Welcome from the Scientific Program Committee Chair

On behalf of the 2015 Scientific Program Committee, I am welcoming you—informatics researchers, practitioners, professionals, students, trainees, colleagues, and most importantly friends—to the AMIA 2015 Annual Symposium here in San Francisco! Hosting AMIA 2015 on the West Coast near Silicon Valley, we offer a special warm welcome to our colleagues in computer science, information science, computational biology, social science. You are joining colleagues from translational bioinformatics, clinical research informatics, clinical informatics, consumer health informatics, and public health informatics eager to meet, collaborate, and learn.

Fueled by the Power of Informatics, the AMIA Symposium is the premier event to present and learn about the latest scientific discoveries, join your colleagues and peers in networking and fellowship, begin lasting collaboration and professional friendships, engage in spirited discussions and debates on controversial informatics topics, learn from others in your field, and connect to the mentors and leaders in informatics.

With two tracks in Foundations and Applied Informatics—often interwoven through joint sessions that allow the leap from base pairs to bench to bedside to patients to populations and back around—the symposium offers a home for all informatics experts to present and share their experience and simultaneously learn both about implementation as well as research.

AMIA 2015 sessions feature full-length papers, abstract presentations, and posters, panel discussions including didactic and interactive panels with extensive audience participation, cutting-edge policy presentations, keynotes, tutorials, system demonstrations, and pre-Symposium workshops. Please review the Schedule-at-a-Glance and use our brand-new mobile App, which is an excellent tool for getting the most out of the meeting.

Highlights

- Keynote Speakers: Avi Rubin, PhD, is a Professor of Computer Science at Johns Hopkins University and will address Information Security in his talk “Hacking Health Care”. Robert M. Wachter, MD is Professor and Associate Chairman of the Department of Medicine at the University of California, San Francisco will focus on Patient Safety
- New in 2015, the Connect-a-Thon pairs AMIA members with leaders in the health care start-up companies to solve problems and develop lasting collaborations.
- Learning Showcase presents new research-focused sessions in the Exhibition Hall
- Student Design Challenge provides students or teams of students with the opportunity to design a solution to an informatics problem.
- The High School Scholars Competition will bring again fresh faces to AMIA to present their work in biomedical informatics summer programs across the country.

I would like to thank my Scientific Program Committee and particularly Vice Chair for Foundations Riccardo Bellazzi, Vice Chair for Applications Sarah Ingersoll and Wanda Pratt, the AMIA 2016 SPC Chair. Along with the amazing AMIA staff, we orchestrated the planning, peer-review, and program design for the AMIA 2015 Annual Symposium. Last, but certainly not least, I would like to thank the 600-plus informaticians who served as subject matter experts in our peer-review process. The success of the Symposium program truly begins with them.

We believe the Scientific Program Committee has prepared a fantastic program. Please be sure to avail yourself of all that the Symposium has to offer—or as much as you can fit in!

Christoph U. Lehmann, MD, FAAP, FACMI
Chair, AMIA 2015 Scientific Program Committee
@culehmann
2015 AMIA Board of Directors

Officers

Blackford Middleton, MD, MPH, MSc, FACMI
Chair
2014 - 2015

Thomas H. Payne, MD
University of Washington
Chair-elect
2015

Steven Labkoff, MD, FACP
Intelligent Medical Objects (IMO)
Treasurer
2014 - 2015

Eneida A Mendonça, MD, PhD, FACMI, FAAP
University of Wisconsin – Madison
Secretary
2014 – 2015

Douglas B. Fridsma, MD, PhD, FACP, FACMI
President and CEO, AMIA

Directors

Martha Bennett Adams, MA, MD, FACP
Working Group Steering Committee Chair
Duke University School of Medicine
2013 – 2015

Wendy W. Chapman, PhD, FACMI
University of Utah
2014 - 2016

Theresa Cullen, MD, MS
Veterans Health Administration
2015-2017

Patricia Dykes, DNSc, MA, RN, FACMI
Brigham and Women’s Hospital
2014 – 2016

Peter J. Embi, MD, MS, FACMI
The Ohio State University
2015 - 2017

Cynthia S. Gadd, PhD, FACMI
Vanderbilt University
2015-2017

John H. Holmes, PhD, FACMI
University of Pennsylvania
2013 - 2015

Curtis P. Langlotz, MD, PhD, FACMI, FSIIM
Stanford University
2015 - 2016

Neil Sarkar, PhD, FACMI
Brown University
2014 - 2016

Dean F. Sittig, PhD, FACMI, FHIMSS
University of Texas Health Sciences Center at Houston
2013 - 2015

Justin B. Starren, MD, PhD, FACMI
Northwestern University Biomedical Informatics Center
2013 - 2015

Jessica Tenenbaum, PhD
Duke Translational Medicine Institute
2015 - 2017

Ex-Officio Board Members

Suzanne Bakken, RN, PhD, FACMI
American College of Medical Informatics President
Columbia University
2015 - 2016

Michael Kamerick, BSCS
Industry Advisory Council Chair
TriNetx, Inc.
2015

Tiffany Kelley, PhD, MBA, RN
Student Working Group Representative
2014 to 2015
Philip Kroth, MD, MS
Academic Forum Executive Committee Chair

Notice

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The authors and the publishers of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standards accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the authors nor the publisher nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete, and they are not responsible for any errors or omissions or for the results obtained from use of such information. Readers are encouraged to confirm the information contained herein with other sources. For example and in particular, readers are advised to check the product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this book is accurate and that changes have not been made in recommended dose or in the contraindication for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.
Model Selection For EHR Laboratory Tests
Preserving Healthcare Context and Underlying Physiology

David Albers¹, PhD, Rimma Pivovarov¹, MA, J Michael Schmidt², PhD,
Noémie Elhadad¹, PhD, George Hripcsak¹, MD MS
¹Department Biomedical Informatics, Columbia University, New York, NY
²Department of Neurology, Columbia University, New York, NY

Introduction
A core task when developing data-driven tools on electronic health record (EHR) data is to model the raw observations in a way that is computationally feasible and that represents the underlying phenomena that generated the observations [1]. While non-parametric models do represent observations in an accurate fashion, their parametric alternative models have the advantages of interpretability (e.g., mean, shape, variance, are all parameters which help describe or summarize raw observations) and known, established properties that can be leveraged (e.g., conjugacy of different known distribution families). Here we study the question of parametric model selection, and focus on laboratory test results (i.e., a range of laboratory tests and the many observed values for these tests in the EHR). Prior work has observed that the health care process (HCP) [1], as defined through measurement context [9] and measurement patterns [2], can influence how EHR data are represented as statistical parameterizations. We present a methodology for model selection of EHR laboratory tests. To assess the value of our methodology, we experiment on two different datasets, generated through different clinical healthcare processes (primary care vs. intensive care). Furthermore, for laboratory tests where the underlying physiology is well established, we examine the validity of the selected model to preserve their underlying physiological properties.

Methods
Study was carried over two cohorts from different contexts. The first includes EHR data collected during a stay in a neurological intensive care unit (ICU) from patients who are comatose. The second cohort (AIM) comprises longitudinal records of patients who visit regularly an outpatient clinic, as well as get admitted and visit the emergency department. The HCPs underlying these data are very different: in the ICU cohort, data are randomly sampled at regular intervals largely independent of the overall health state of patients, while in the AIM cohort, data are sampled primarily during visits, distributed through time as patients gets sick.

We use a kernel density estimate (KDE) [2] of patient laboratory data as a non-parametric gold standard model. We then fit the data to 10 different established, parameterized models (e.g., Gaussian, Gamma [4], Generalized Extreme Value (GEV) [5], etc.). The most representative model is selected using a variation of an information criterion based goodness-of-fit measure, the KL-divergence [3] between the gold standard KDE and our parametric models. This model evaluation technique can be used in a high throughput setting and is applicable to a range of applications from phenotyping to cohort selection. Finally, we verify that the model evaluation methodology (KL-divergence) selects a realistic model by showing that for glucose the best parametric model preserved known physiologic relationships, specifically, that mean-like and variance-like quantities increase simultaneously [7-8].

Results
For the ICU cohort, the parameterization that minimized the KL-divergence was the gamma distribution. The mean-like and variance-like gamma parameters increased simultaneously (Fig. 1). In contrast, no other model, including the next best model (Fig. 2) reproduced that physiologic relationship. That the gamma distribution was chosen is reassuring because it is the maximum entropy model for any system whose mean-like and variance-like quantities are linearly related [4]. In contrast, for the AIM cohort, the GEV was the parameterization that minimized the KL-divergence. The mean-like and variance-like GEV parameters increase simultaneously (Fig. 3), reproducing the known physiologic feature. No other model reproduced that physiologic relationship without human intervention (Fig. 4). The GEV is the generating process for the measurement of extremes of a distribution [5], implying that the AIM data are generated by a process that measures the extremes of the physiologic process, revealing effects of the HCP.

Discussion
We have shown that in different clinical contexts, different models of data may be appropriate, and we believe that the cause is not so much a change in physiology, but a change in the way health is measured in the different contexts. That is, the HCP causes different but measurable biases in the data. In the ICU, the HCP measurement function does not appear to have a strong influence on glucose measurements. This implies that we can treat and use ICU data more like continuously sampled physiologic data. In contrast, the process that generates or collects data from outpatient, or mixed outpatient/inpatient settings, does influence the data collected. If the correct model is not chosen, the physiologically expected relationships between parameters are lost. Fortunately, selecting a model that minimizes the KL-divergence between a model and the KDE, a methodology that can be used in a high throughput setting, can correct for the bias due to context. Meaning, selecting the model that minimizes the KL-divergence seems to minimize the impact of the HCP on the modeling of the data, allowing us to identify the most physiologically faithful representation of the physiologic process within EHR data.

Analysis and Classification of Patient Safety Reports in Computerized Prescriber Order Entry (CPOE) Systems and Refinement of a New Taxonomy for Classification of CPOE-Related Medication Errors

Mary G. Amato, PharmD, MPH 1,2, Alejandra Salazar, PharmD 1, Thu-Trang Hickman, MPH 1, Arbor J.L. Quist 1, Lynn Volk, MHS 3, Adam Wright, PhD 1,4, Dustin McEvoy 3, Sarah P. Slight, PhD, PGDip 1,5, David W. Bates, MD, MSc 1,4, Gordon D. Schiff, MD 1,4

Introduction

CPOE has been shown to reduce medication error rates overall, but can also facilitate the risk of some types of prescribing errors.1 Obtaining the full safety benefits of CPOE demands that organizations develop approaches to identify and address the causes of these new errors. The aim of this study was to classify and analyze errors related to CPOE with ongoing development and refinement of a taxonomy classification system for CPOE-related errors.

Methods

We reviewed medication-related patient safety and error reports from January-December 2013 (n = 2522) from six sites that participated in an FDA-sponsored project examining safety issues in CPOE systems. Two pharmacists reviewed the error narrative reports and identified those that occurred in the ordering/prescribing phase of medication use that were related to the use of CPOE. For those related to CPOE, we assessed whether CPOE facilitated (i.e. actively contributed to) the error or failed to prevent the error (i.e. CPOE system improvements may have prevented the error). A taxonomy which classified errors related to CPOE developed in a previous project was revised and updated in order to classify the reports regarding what happened to the patient, what happened in CPOE, and, if it could be determined from the report, why the error occurred.2 The taxonomy was iteratively refined as more cases were reviewed and different types of errors were found.

Results

Of the 2522 medication error reports reviewed, 1214 (48.1%) were deemed not related to CPOE mainly because they did not occur in the ordering phase or did not involve an electronic order. Of the remaining 1308 reports, CPOE was thought to facilitate the error in 171 (13.1%) and failed to prevent the error in 1137 (86.9%). The final version of the taxonomy included 14 categories describing what happened to the patient, 40 categories describing what went wrong when entering the order in CPOE, and 71 potential factors contributing to why the error occurred. The three most frequently cited reasons for what happened when entering the order in CPOE were “Other: Entered order not routed to/received at intended destination”, “Dose: Ordered wrong dose or strength”, and “Drug: Duplicate order: Same exact drug” (Table 1). A wide variation was seen in the format, categorization, and quality of the narratives, making it difficult to use the taxonomy to classify what happened and why in some cases.

Discussion

The leading errors related to CPOE were those related to transmission errors, erroneous dose, and duplicate orders. Our review of error report narratives was useful in further refining a taxonomy classifying CPOE-related errors. A more standardized safety reporting process using a common taxonomy in systems across healthcare facilities would enable healthcare systems to learn more about the causes of and implement prevention strategies for these errors.

Introduction

In the seminal paper in 2004, van Eaton and colleagues described the content needs of residents regarding electronic rounding and handoff documents (1). Several common themes emerged from this work and subsequent studies (2,3). Despite the decade of literature that has followed since this work, standardization of content of electronic rounding or handoff documents to better inform EHR vendors is lacking. To formulate a basis for electronic rounding and handoff document standards and determine the current needs, we engaged in a three-part investigation: 1) searching the literature to determine content in EHR-based rounding and handoff documents, 2) examining the content of these documents at our own institution, and 3) interviewing resident physicians regarding their attitudes and opinions about present document content.

Methods

Review of the literature revealed at least one existing standard and several common themes in standard EHR rounding and handoff document content (4,5). To gain an understanding of the data elements in rounding and handoff documents in use at our own institution, we gathered 18 documents from 18 different clinical service teams and extracted content headings. We then normalized these to the Clinical Document Architecture (CDA) Continuity of Care Document (CCD) standard and other common data field themes obtained from the literature and tabulated the results. To gain insight into content evaluation by resident physicians, we engaged residents from Internal Medicine, Pediatrics, and Surgery (n=16) in semi-structured interviews. Open-ended questions regarding rounding and handoff document content value and perceived accuracy, as well as missing or desired elements, were asked and answers recorded. Sample rounding and handoff documents were utilized during the interviews. Interview content was analyzed and answers quantified.

Results

Only 3 out of 18 documents described \textit{Code Status} despite this information being highly reported of value in the literature. In contrast, 16 of 18 documents contained some form of documentation on \textit{Plan of Care}, consistent with the high value placed on anticipatory guidance in the literature. Surgical residents demonstrated greater consistency in utilization of data fields, with 4 of 11 categories utilized by 100\% of interviewed subjects. In contrast, neither Pediatric nor Internal Medicine team members unanimously employed any given data field. Internal Medicine teams also had the highest level of mistrust of data elements, with a near equal mix of manually entered and EHR populated elements. When asked about desired improvements, Internal Medicine and Surgery residents both dedicated more than 50\% of their comments to \textit{Medications} and \textit{Hospital Course}, which are fields that contain a near even mix of manually entered and EHR generated data. The predominant themes limiting user satisfaction in EHR generated documents related to timeliness of populated values compared to when the information is used, and excess of “noise” of data not perceived as useful, which precluded efficient identification of valued elements. In contrast, manually entered fields were nearly always considered suspect for accuracy of updates, and their success depended largely on daily work burden associated with maintaining their content.

Conclusion

There has yet to emerge a standard for EHR-based rounding and handoff documents. There appears to be significant overlap of resident physician needs with content elements published in the literature, as well as additional areas of development and improvement desired for these tools to optimize communication and use of these tools for patient care.

STEMPOWERMENT: A Prototype Online Intervention to Improve Outcomes in Stem Cell Transplant Survivors

Martha Askins, PhD1, Jeffery McLaughlin2, Susan Peterson, PhD1, Dongsong Zhang, PhD3

1 MD Anderson Cancer Center, Houston, TX, 2 Radiant Creative Group, LLC, Houston, TX, 3 The University of Maryland Baltimore, County, Baltimore, Maryland.

Abstract

Stem cell transplantation survivors face numerous physical and psychosocial challenges during recovery. Low adherence to recovery behaviors can result in poor health outcomes and increased risk of death. We designed and evaluated a prototype online social intervention that utilized game mechanics to promote post-transplant self-management behaviors among AYA survivors; namely, medication adherence, hydration, and physical activity.

Background

Hematopoietic stem cell transplantation (SCT) is a life-threatening, intensive treatment regimen involving a lengthy hospital stay and a protracted recovery period. During recovery, SCT survivors encounter numerous physical and psychosocial barriers to adherence with medication regimens and maintenance of adequate hydration and physical activity levels; low adherence can result in serious consequences such as organ damage and/or chronic, severe graft vs. host disease. This is especially true for adolescent and young adult (AYA) SCT survivors, whose developing autonomy and enjoyment of peers is often juxtaposed with the constraints of cancer treatment. We evaluated a prototype online interactive intervention utilizing game mechanics to promote post-SCT self-management behaviors among AYA survivors; namely, medication adherence, hydration, and physical activity.

Methods

The prototype intervention implemented an online social network that incorporated game mechanics and collaborative problem solving. Technical merit, feasibility and usability of the intervention were evaluated using the framework of the Technology Acceptance Model (TAM), and incorporated constructs related to system performance, perceived enjoyment, behavioral intention to use the system, and usage behavior. Participants included AYA allogeneic SCT survivors who accessed the intervention site for up to 3 weeks; they subsequently completed an evaluation comprising a 52-item TAM measure and semi-structured interviews.

Results

16 AYA allogeneic SCT survivors participated; 52% were female, mean age was 22 years (range 18-28). The overall mean TAM score was 6.2 (SD=2.1, range 1-7); subscale scores ranged from 5.7 (lowest) on perceived usefulness to 6.9 (highest) on behavioral intention. Qualitative responses indicated that users valued the ability to create personalized profiles, learning self-management strategies, and social networking with AYA SCT survivors. Desired feature enhancements included more interactive activities and information on long-term coping after SCT.

Conclusions

Results showed high usability, feasibility and satisfaction ratings with the intervention, and a desire for long-term coping information post-SCT and more interactive features.
Assessing Variability in Breast Cancer Treatment Paths Using Frequent Sequence Mining

Ravi V. Atreya¹, Thomas A. Lasko, MD, PhD¹, Mia A. Levy, MD, PhD¹
¹Vanderbilt University School of Medicine, Nashville, TN

Introduction
Quality measurement of breast cancer treatment paths can help healthcare providers and organizations improve the delivery of care and engage with patients. A major component of tracking clinical quality is assessing the variability in care. In this work, we aim to use frequent sequence mining to identify frequently occurring event patterns to help us represent infrequently occurring treatment paths. It is important to identify infrequently occurring treatment paths to understand why deviations from the standard of care are occurring and what the resulting patient outcomes are. Given the proliferation of quality measures in breast cancer care, breast cancer centers are facing growing pressures to understand the treatment paths of their patients in order to improve the care they provide.

Methods
We selected adult women diagnosed with stage I-III breast cancer between 2000-2012 from the cancer registry at Vanderbilt. We extracted treatment event data from the cancer registry and focused on the four primary modalities of breast cancer treatment: surgery, chemotherapy, hormone therapy, and radiation therapy. We represented surgical events as either breast conserving surgeries or mastectomies. We generated treatment event sequences by placing events in sequential order based on their timestamps.

We used the SPADE event sequence mining method² in the arulesSequences R package³ to identify treatment event patterns within the event sequences. A treatment event pattern is a subset of an event sequence; for example, a “breast conserving surgery—radiation therapy” event pattern is a subset of a “breast conserving surgery—chemotherapy—radiation therapy” event sequence. We ranked the treatment event patterns by their frequency (0.5% cutoff) and calculated the number event sequences that the most frequent treatment event patterns were present in. This analysis is aimed at representing the variability in the treatment event sequences by using frequently occurring treatment event patterns to assess infrequently occurring treatment event sequences.

Results
We extracted 1528 patient records and their treatment events from the Vanderbilt cancer registry. We generated 265 unique treatment event sequences for the 1528 patients. Ninety percent of the patient population could be represented by the top 126 (47.5%) treatment event sequences. We plotted the distribution of treatment event sequences across our patient population (Figure 1, left). This demonstrates how a majority of the patient population shares a common set of treatment event sequences. The other 10% of the population, however, is represented by the bottom 139 (52.5%) treatment event sequences. This long tail in the distribution represents variability in breast cancer care.

We next identified 144 frequently occurring treatment event patterns using the SPADE sequence mining method and plotted their distribution across our patient population (Figure 1, right). Ninety percent of the patient population could be represented by the 52 (36.1%) most frequently occurring treatment event patterns of at least two events. Of the 153 patients (10% of population) represented by 139 treatment event sequences (the long tail), 95% were successfully represented by the seven (4.9%) most frequently occurring treatment event patterns of at least two events. The most frequent event pattern of at least two events (breast conserving surgery—radiation therapy) is an important quality measure in breast cancer care. Finally, we visually represented a subset of surgically relevant treatment event patterns in hierarchical fashion to show how frequently occurring event patterns can be joined together to generate longer, more infrequently occurring event patterns and, eventually, event sequences (Figure 2).

Discussion
We represented the variability in breast cancer care by assessing the distribution of treatment event sequences and aligning them with our frequently occurring treatment event patterns. Infrequent treatment event sequences (long tail) were represented by the seven most frequently occurring event patterns. The diverse set of treatment paths, could still be represented through a small set of treatment event patterns. We plan to cluster our treatment event sequences using the results of our frequent event sequence mining approach.
Figure 1. Distribution of treatment event sequences (left) and frequently occurring treatment event patterns (right). The left side shows 265 unique treatment event sequences ordered by frequency in the patient population. The right side shows 144 frequently occurring treatment event patterns ordered by frequency in the patient population. The color represents the first event in the sequence & pattern.

Figure 2. Hierarchy of frequently occurring treatment event patterns focused on surgical care. This shows how frequently occurring event pattern parents can be joined together to generate longer, more infrequently occurring event pattern children. While the BCS, Mast, C pattern only occurs in 3% of the population, its parents C,Mast & BCS,C occur in 12% & 21% of the population, respectively. Color scheme similar to Figure 1.

Six Important Requirements for Patient Hand-Off Application in Inpatient Hospital Setting

Soehi U. Ayubi, PhD, Alexandra C. Pelletier, MBA

1Innovation Acceleration Program, Boston Children’s Hospital, Boston, MA

Abstract
We present six important and required requirements for patient hand-off application in an inpatient setting using bring-your-own-device (BYOD). The requirements are learning lessons from developing and piloting a hand-off application at Boston Children’s Hospital.

Introduction
Caring for hospitalized patients with many team members in an inpatient environment is complex, and hand-off communications among the team members are a leading cause of medical errors.1 The members often have many tasks, divide their attention between multiple tasks and patients, and have high demands around communication and documentation.2 Physicians often use paper checklists to track their daily tasks and facilitate hand-offs.3 Paper is really convenient, but is a static, redundant, unstandardized, unshared, and insecure medium.4 Checklists are seldom available in commercial electronic medical records (EMRs) and often lack mobile, live-tracking components, and often provide only limited integration with EMRs.5 Non-EMR checklists applications are also available to emulate these paper task lists, but may not have required security or privacy controls, may not be integrated with EMRs, and may not be supported by local institutions.

Collaborative Real-Time Mobile TaskList Application
The FastTrack Innovation in Technology team at Boston Children’s Hospital (BCH) developed the first custom build BYOD iOS application, TaskList. It lists shared tasks for a patient and allowed the physician team to use their own devices to check and update tasks through the course of the day and automatically provide live updates to the team members (Figure 1). TaskList is integrated with Epic and Cerner EMRs and complies with Health Insurance Portability and Accountability Act (HIPAA) security and privacy standards. The application was piloted with an inpatient pediatric ward resident team. Using usability survey, we found the application is easy and convenient to use and the team found it is helpful in structuring discussion and task management for patients.

Six Important Characteristics for Patient Hand-Off Application in Inpatient Hospital Settings
Before and during the development of TaskList, we identified a list of fundamental and important requirements for patient hand-off application through a review of literature studies, discussion with external security experts, and reviews with Information Systems Department of BCH. Description and implementation on TaskList for each requirement are listed in Table 1. We used these requirements to build the TaskList application.

Conclusion
We developed and piloted an application designed to facilitate collaborative work and learning and hand-off among physicians using their own devices. We identified that Secure, Integrated, Real Time, Mobile, Collaborative, and Usable are six important and fundamental requirements needed to implement such an application.

Capturing Preventive Care Services: Comparing Data Obtained from Manual Chart Review, Automated EHR Extraction, and Insurance Claims

Steffani R. Bailey, PhD¹, Megan Hoopes, MPH², Heather Angier, MPH¹, Rachel Gold, PhD, MPH², John Heintzman, MD, MPH¹, Miguel Marino, PhD¹, Jean P. O’Malley, MPH¹, Jennifer E. DeVoe, MD, DPhil¹²

¹Oregon Health & Science University, Portland, OR; ²OCHIN, Inc., Portland, OR; ³Kaiser Permanente Northwest Center for Health Research, Portland, OR

Introduction

Historically, healthcare quality measures were often derived from: 1) administrative health insurance claims, which fail to capture unbilled services; or 2) manual review of patients’ charts, which is time-consuming, expensive, and often completed on only small subsets of patients. Automated extraction of EHR data presents an efficient, scalable method to assess clinical care quality in large groups of patients. Published comparisons between automated extraction of EHR data and manual chart review have shown mixed results. To further this previous work, we compared automated EHR data extraction to manual chart review on six adult preventive care services that are often performed in the primary care setting (i.e., no referral needed). We also compared Medicaid claims data to manual chart review on the same subset of patients.

Methods

We obtained patient-level data from a linked, hosted EHR serving the OCHIN network of >300 primary care clinics in 16 states. The population was 13,101 adult (ages 19-64), continuously insured Medicaid recipients in Oregon with ≥1 primary care office visit at a study site in 2011. Using automated queries from the EHR, we extracted data on six preventive service metrics ordered or received in 2011: body mass index (BMI), blood pressure, and smoking status assessment; cervical cancer screening; chlamydia screening; and cholesterol testing. EHR data were linked to administrative Medicaid claims data on a unique identification number. From this population, we randomly sampled 150 patients that met age, gender, and clinical eligibility for each screening measure (e.g., cervical cancer screening among women ages 19-64 without total hysterectomy). Manual chart review was conducted by a trained staff member. Prior to completing the chart review, the primary reviewer and a physician-researcher independently reviewed a subset of charts and inter-rater reliabilities were computed. Using standard measures of correspondence (e.g., kappa statistic, sensitivity, specificity), we compared agreement between manual chart review (considered the ‘gold standard’) and the other two data sources on patient-level receipt (yes/no) of each measure.

Results

The patient population from which our subsamples were drawn was primarily female (66%), non-Hispanic white (68%), and low income (92% had family incomes ≤138% of federal poverty level). The mean age was 41 years. Inter-rater reliability was high, with kappa statistics ranging from 0.7-1.0. Automatic data extraction agreed perfectly with manual chart review for BMI and blood pressure assessment and demonstrated very high (>90%) agreement on other measures. Chlamydia screening was captured nearly equally well using the automated method (kappa=.97, sensitivity=.96, specificity=.98), while the assessment of smoking status showed lower agreement (kappa=.66, sensitivity=.97, specificity=.67). Agreement between claims data and manual chart review were low for blood pressure, BMI, and smoking, services that typically do not generate a claim. There was moderate agreement on chlamydia (kappa=.59), cervical cancer (kappa=.67), and cholesterol (kappa=.76) screenings. Agreement between claims data and manual chart review data was lower for all measures compared to agreement between the manual chart review and automated EHR data extraction.

Discussion

Healthcare organizations need accurate methods for evaluating and reporting the quality of care they provide to patients. EHRs are increasingly being used to evaluate quality of care; thus, it is necessary to assess the validity of these data for this purpose. In this study, we found very high to perfect agreement between automated EHR data extraction and manual review of the patient chart, while claims data largely failed to capture unbilled preventive care services typically received in the clinic. These findings suggest that automated EHR extraction is a valid method for capturing preventive service care quality, with advantages over claims data.

Introduction

Healthcare providers prescribe medications with the intention to treat or prevent disease. However, according to the World Health Organization, only half of the patients in developed countries adhere to their prescribed medication regimen.

Medication management for pediatric patients poses higher safety risks because children are less able to tolerate errors due to limited internal reserves. It is important that medications for a pediatric patient are administered as intended by the provider. A PubMed search for (“Inpatient” [Mesh]) and (“Medication Compliance” [Major]) did not return any studies conducted on medication compliance for a pediatric inpatient cohort. We studied the compliance rate for pediatric inpatients concentrating on medications not administered to the pediatric inpatient population of the Vanderbilt Children’s Hospital (VCH), which is part of the Vanderbilt University Medical Center (VUMC).

METHODS:

With the IRB approval, we collected order and administration data for pediatric inpatients from the Enterprise Data Warehouse (EDW) at VUMC. We focused only on the medication orders and excluded the orders for which the administration was not mandatory (e.g., PRN orders), was not routinely recorded as medication (e.g., intravenous fluids), or those for discontinuation of medications. We identified the orders without a corresponding administration record as ‘missed-admin’. The set of orders for which the corresponding administration records suggested non-administration was labeled “non-admin” set. Nurses at VUMC must indicate a REASON if a medication was not administered or delayed. We also analyzed the ‘missed-admin’ & ‘non-admin’ sets with respect to the medication class.

RESULTS:

We isolated 1,570,994 medication orders, spanning 42 months (July 1, 2010 through December 31, 2013), corresponding to 117,188 distinct pediatric inpatients. There were 3,742,013 matching administration records for these orders. Only 596 distinct medication order records did not have a valid matching administration record (missed-admin) (Table 1).

For the non-admin, we grouped the REASON-CODEs into three categories: “Administered per protocol” (medication was given but in a modified manner – e.g., when the patient was off the unit), “D/C per protocol” (circumstances like being in surgery prevented administration), and “Not administered”. There were 101,688 administration records in the “Non Administered” category, corresponding to 41,099 medication orders. The top two medication classes comprising the missed and non-administered doses were “Alimentary tract and metabolism drugs” (e.g., Docusate Sodium, Creon) and “Nervous system drugs” (e.g., Morphine, Fentanyl)

DISCUSSION and CONCLUSION:

The medication process (ordering, dispensing, and administration) in pediatric care is complex. Health information technology can help to measure the quality status of the medication process at various levels. To our knowledge no studies have ever evaluated medication administration compliance in a children’s hospital.

The small number of missing administration records (596 of the total 1,570,994 orders – < 0.05%) demonstrates the robustness of the electronic Medication Administration Records (eMAR), which prompts nurses to document every scheduled dose. This small gap could reflect truly not administered and undocumented doses. The non-admin records corresponded to < 3% (41,099) of the distinct orders. The absolute number may seem concerning, however breakdown of reasons demonstrates that the majority were compliant.

Our findings suggest that the medication process in pediatric practice is rational and reliable.

The Hidden Life of Nurses’ Cognitive Artifacts

Jacquelyn W. Blaz, MS1, Alexa K. Doig, PhD, RN1,
Kristin G. Cloyes, PhD, MN, RN1, Nancy Staggers, PhD, RN, FAAN1
1University of Utah, Salt Lake City, UT

Introduction

Standardizing handoffs is recommended to improve communication, with electronic tools as the primary approach. However, nurses continue to rely on paper-based tools to support handoffs, indicating a deficiency in available electronic versions. Nurses’ paper tools have been described as cognitive artifacts1,2—tools that provide cognitive support by offloading part of the cognitive work required for a task from the human mind to an external object. Characterization of nurses’ cognitive artifacts as merely handoff tools may be a limited view of the purposes these objects serve and the processes leading to their construction. Previous research hints at uses beyond handoff, but little work has been done to examine uses outside the context of handoff1,2. Electronic tools developed to support nursing handoff that disregard nurses’ cognitive needs beyond handoff may be doomed to be underutilized. The purpose of this research was to develop a deep understanding of the use and production of nurses’ paper cognitive artifacts in a medical oncology unit.

Methods

A grounded theory approach3 was used to explore nurses’ handoff artifacts. Seventy-three hours of field observations in a medical oncology unit in a cancer specialty hospital led to 13 purposively sampled nurses. These nurses were shadowed for an entire shift and interviewed after giving handoff to the next shift. The data corpus included images of paper cognitive artifacts, transcribed interviews, field notes, and analytic memos. Consistent with grounded theory techniques, the data were coded and collected into categories of similar ideas. Concepts emerged from further analysis and interpretation of codes and categories.

Results

Nurses' paper-based artifacts are deemed by nurses to be personal, dynamic, living objects that traverse a life cycle during each shift and evolve during the course of a nurse's career. The life cycle has four phases. Origin occurs with the creation of a new artifact at the beginning of the shift; the second phase is the use of the artifact throughout an entire shift; reproduction is the transfer of information by a nurse from an old artifact to a new one; and the final phase occurs with the destruction of an artifact when it is considered no longer useful.

Nurses' paper artifacts experience an evolutionary process over nurses’ careers. Evolution in a nurse's individually styled, paper artifact is triggered by a change in the nurse's environment that reshapes cognitive needs. If an artifact is not able to provide cognitive support in a new environment, it is modified into (adapted), or abandoned for (made extinct), a different format that will provide the necessary support. For example, a newly hired nurse may create an area to record information related to chemotherapy regimen to an existing paper tool s/he created for use on a general medical unit. With each new nursing shift and artifact life cycle, a nurse may either abandon or modify the artifact until a new design solidifies that is “good enough” for the nurse's cognitive needs.

Discussion

The two processes of nurses’ cognitive artifacts--life cycle and evolution--point to the need for extreme flexibility in future designs of standardized handoff tools, especially electronic versions. Individual cognitive needs may not always be in congruence with group needs, thus a ‘one-size-fits-all’ approach to design for an electronic handoff tool is not recommended. Not only must electronic tools have the ability to be updated quickly and easily by the user during a shift, but the overall display design must also be changeable by an individual nurse for the immediate context of work, the patient's condition and to accommodate changes in cognitive work over time. This could be addressed with periodic evaluations of how an electronic form is working for nurses on a unit, especially following policy changes affecting nursing workflow or by utilizing a display design consisting of modules of related information placed according to the preference of individual nurses.

Introduction: Active learning techniques are to select samples for annotation based on an estimation of their utility for predictive modeling, rather than at random. They have been studied in biomedical natural language (NLP) tasks, such as assertion classification for clinical concepts1, word sense disambiguation in biomedical literature2, and phenotyping from electronic health records.3 These studies have demonstrated that active learning can help achieve high-quality supervised classification models with reduced annotation cost. Most of these simulated studies assume that annotation cost for each sample was identical. In reality, however, annotation cost (i.e. the time required by an annotator) can be very different from one sample to another. In this study, we evaluated the real-time performance of active learning versus passive learning for a clinical named entity recognition (NER) task. Active LEARNER, an active learning enabled annotation system for NER, was developed to support the user study. We collected the annotation data from two nurses and generated learning curves, analyzing F-measure of NER models as a function of real annotation time, for both active and passive learning. We find that active learning is not guaranteed to reduce actual annotation time to achieve a model with desired performance, when compared to passive learning.

Methods: The clinical NER task in this study was to extract problem, treatment, and lab test concepts from clinical notes. We used the 2010 i2b2 NLP challenge dataset to generate the querying pool and test set for the NER model assessment, and to evaluate the annotation quality. Our study consists of three parts: (1) development of Active LEARNER, (2) user study design, and (3) evaluation:

(1) We propose Active LEARNER, which uses a preprocessed unlabeled corpus as the input, actively queries sentences and presents them to the interface for annotation, and generates NER models in real time. There are three major components of the system: annotation interface, learning engine, and querying engine. For the annotation component, the system embeds “brat”, a rapid annotation tool2, as an interface for entity tagging. The learning engine is based on the CRF algorithm implemented by CRF++.7 The querying engine implements our newly developed active learning algorithm called CAUSE (Clustering and Uncertainty Sampling Engine), which considers both uncertainty and diversity of sentences in the corpus. Figure 1 presents the multi-thread workflow design of Active LEARNER. The learning process, which mainly includes CRF model encoding and unlabeled sentences ranking, is parallelized with the annotation process. We upload a video online6 to demonstrate the annotation process using our interface.

(2) In the user study, CAUSE and RANDOM sampling methods represent active learning and passive learning, respectively. We recruited two nurses to participate in the user study of Active LEARNER. To ensure that the results from the two methods are comparable, users need to be well trained and perform consistently in both experiments. Therefore, the user study includes two parts: (a) annotation training, and (b) the main study. Annotation training includes review of annotation guidelines, a review of some sentence-by-sentence annotations, and annotation practice. Once users had completed the training, they started the main study for each method with section management.

(3) We analyzed users’ responses over time on both methods in the main study. The evaluation metrics included words/sentences per minute (average sentence length), entity annotations per minute (annotation speed), words per minute (reading speed), and F-measure (annotation quality, based on i2b2 gold standard). We plotted the annotation curves for some of these responses (e.g. entities versus annotation time and words versus annotation time) for the two users across the two methods. We also show the learning curves of NER modeling (e.g. F-measure versus annotation time) across the two methods and the two users. A survey of the two users was done to gain their general impression on the difference between the two methods from the perspectives of annotation difficulty, clinical relevance of sentences, diversity of sentences, etc.

Results: Figure 2 shows the annotation curves of reading speed and annotation speed by RANDOM and CAUSE for user 1. Figure 3 shows the same types of curves for user 2. In terms of the overall annotation speed, user 1 annotated 7.83 and 7.71 entities per minute by RANDOM and CAUSE, respectively, while user 2 annotated 7.28 and 7.94 by RANDOM and CAUSE, respectively. Both users achieved F-measures ranging from 0.79-0.81 for overall annotation quality for each method. Figure 4 presents the learning curves of NER modeling by the two methods from the two users. The learning curves show that RANDOM performed slightly better than CAUSE (by eye) for user 1, while CAUSE slightly outperformed RANDOM for user 2.

Discussion: Active learning selected longer and more clinically relevant sentences compared to random sampling. However, annotating the actively selected sentences was more difficult (by survey) and took more time. While previous studies have found increased NER performance per training sentence using active learning, we found no reliable increase in performance per annotation time, suggesting that the increased information content of actively selected sentences is strongly offset by the increased time required to annotate them. Moreover, the higher annotation speed from users induced better learning curves. Interestingly, the overall reading speed is also higher for randomly sampled sentences (62-68 words per minute) compared to actively selected sentences (53-54 words per minute). Our results demonstrate the need to benchmark active learning algorithms using real-world practical measures (such as user time) in addition to more theoretical measures (such as the number of training sentences). The next phase of our work will include improving our active learning algorithms against the practical measures.

A REAL TIME ELECTRONIC REGISTRY AS A KEY INTERVENTION TO REDUCE TREATMENT DISPARITIES IN EARLY STAGE, NON-SMALL CELL LUNG CANCER: PRELIMINARY RESULTS

Samuel Cykert, Paul Walker, Peggye Dilworth-Anderson, Maria Cirino-Marcano, Lloyd Edwards

INSTITUTIONS:
1. General Medicine and Clinical Epidemiology, University of North Carolina, Chapel Hill, NC, United States.
2. Leo Jenkins Cancer Center, Brody School of Medicine, Greenville, NC, United States.
3. Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States.
4. Pulmonary and Critical Care, University of South Carolina School of Medicine, Columbia, SC, United States.

INTRODUCTION: African-Americans (AA) with lung cancer experience a higher annual death rate compared to Whites (W) with AA men particularly affected (78.5 vs 65.7 deaths per 100,000 population). Despite this risk, Bach and others have shown that over the last 3 decades surgical rates for AA patients with potentially curable stage 1 and non-small cell cancer lag behind surgical rates for W patients. Although stereotactic radiation cures some patients with smaller lesions, lung cancer surgery remains the treatment of choice according to National Comprehensive Cancer Network guidelines. These guidelines were further supported by Gray et al. who demonstrated in a small areas analysis that regions of the U.S. with high surgical rates (>79%) have less lung cancer mortality than areas with lower surgical rates even considering high risk patients. These results make the treatment difference all the more remarkable. Because of the surgical gap and associated mortality differences, we launched a multifaceted interventional trial designed to optimize lung surgery rates for all patients with early stage lung cancer reduce disparities associated with AA race. We report the early results of this effort.

METHODS: We first performed a 3-year retrospective chart review for all patients with biopsy proven lung cancer at 3 academic institutions to establish baseline surgical rates according to demographic features, including race, and severity of illness. Starting September of 2012, we prospectively recruited patients with Stage 1 or 2 non-small cell lung cancer who were identified at initial visit scheduled with a pulmonologist, surgeon, or at a multidisciplinary lung cancer clinic at the 3 institutions where the retrospective chart reviews were performed. Patients were approached if he/she had either biopsy proven disease or qualified through a Bayesian probability algorithm based on the results of a recent chest computerized tomography scan. This report includes patients who reached study endpoints (treatment given or no treatment administered within 4 months of enrollment) by January of 2015. Immediately after enrollment, we then applied the multipronged intervention that used digital systems, quality improvement techniques and an enhanced care team at each study site. The specific intervention components are as follows:

(1) a real time electronic registry that provides an electronic warning within the registry if either a patient misses an appointment or doesn’t reach a designated milestone in care. Data in the registry for appointments, procedures, and diagnostic tests are derived from electronic health records. Warnings were either noted by the enhanced care team or delivered to members of the usual care team.

(2) quarterly feedback of surgical rates by race and co-morbid illness to providers and other cancer care personnel in the participating centers. This data reporting creates an environment of transparency.

(3) a specially trained navigator who develops patient rapport early then reengages patients immediately after any lack of adherence to appointments or recommended care. If a real time registry warning occurs because a care milestone has not been reached, the navigator is also empowered to address this circumstance with the care team.

Given that electronic health records are now ubiquitous, interventions (1) and (2) were used for all patients and compared to retrospective controls. Consented patients were randomly assigned (3) to special navigation or usual care.

RESULTS: Baseline surgical rates from the retrospective analysis of 714 early stage, non-small cell patients were 69% for W and 66% for AA patients. When controlling for comorbidities, COPD, age, and other demographic data, the Odds Ratio for surgery for AA compared to W lung cancer patients was 0.64 (95% CI 0.43, 0.96). To date 157
patients have prospectively reached study endpoints including 54 AA patients (34%). The mean age for this study group is 65 years; 53% are female. 49% were assigned to special navigation. Preliminary findings show an overall surgical rate of 81% (82% W, 78% AA, p = 0.5). In multivariate analysis, using demographic variables, comorbid illness, pulmonary function, and patient perceptions of communication as independent variables, age > 70 (OR 0.18, 95% CI 0.38, 0.83) and a forced expiratory volume < 40% of predicted (OR 0.04, 95% CI .001, 0.19 ) were associated with lower surgical rates. Notably, AA race and medical comorbidity scores did not affect surgery.

CONCLUSION: Early results from a multifaceted intervention designed to optimize lung cancer surgery and narrow the surgical gap between AA and W patients appear promising.

Improving Care Team Communication: Early Experience at Implementing a Patient-centered Microblog

Anuj K Dalal, MD,1,2 Jeffrey L Schnipper, MD, MPH,1,2 Anthony Massaro, MD,1,2 Kelly McNally,1 Patricia Dykes, RN, DNSc,1,2 and David W Bates, MD, MSc,1,2

1Brigham and Women’s Hospital, Boston, MA, 2Harvard Medical School, Boston, MA

Introduction: Care team communication in acute care settings is fragmented, inefficient, and difficult.1,2 Inpatient and ambulatory providers frequently communicate asynchronously via alpha-numeric pagers, network email, and increasingly, unsecure texting to discuss and coordinate the patient’s plan of care. We engaged institutional stakeholders in the design and development of a patient-centered microblog. The patient-centered microblog aims to facilitate seamless care team communication by accurately and reliably identifying care team members and directing providers to a single conversation thread on which to view and contribute to the patient’s plan of care discussion. The platform supports access from web-enabled desktop computers and mobile devices and is a component of two institutional initiatives–PROSPECT and PCORI Transitions–that serve to promote patient-centered care team communication during hospitalization. The purpose of this study is to describe our experience at implementing the patient-centered microblog in the acute care setting.

Methods: This study took place at a large academic medical center in Boston, Massachusetts. The system was implemented on 2 MICU, 2 Oncology, and 2 General Medicine units. We presented a structured overview to attendings, housestaff, physician assistants, fellows, nurses, social workers, care coordinators, primary care physicians, and case managers throughout the study. During each session we reviewed secure log-on, core functionality (real-time care team member identification, read-receipts, persistence of messages on threads, admission and message notifications, etc.), workflow integration, and mobile access. We measured messaging activity over a 2-month period after core functionality was fully implemented. We recorded all feedback. We conducted three, 1-hour focus groups with 4-6 providers (housestaff, physician assistants, and nurses who had worked on intervention units). We conducted ½-hour interviews with intervention unit leadership (3 physicians, 3 nurse managers). We addressed the following categories: core functionality, actual clinical use, notifications and alert fatigue, barriers to use, and desired enhancements. We used content analysis methods to interpret descriptive data from focus groups and interviews. We used a 2-person consensus approach to identify major themes.

Results: In general (Figure 1), the volume of weekly messages increased over time (Figure 1a), but varied by type of clinical unit (Figure 1b). Of 11,277 message notifications sent, 8308 (74%) were viewed by the notified recipient. See Table 1 for descriptive feedback and derived themes. Overall, core functionality was favorably received and actual clinical use matched intended use-cases. Concerns regarding alert fatigue were present but reflected variable understanding of functionality that was incorporated to minimize excessive notification. Barriers to using the system–namely, competing messaging systems (e.g., email) and maintaining accuracy of care team member role assignments from scheduling systems–did not seem insurmountable. Strategies to overcome these barriers included active participation by intervention unit leadership and alignment with institutional culture change initiatives. Requests for enhancements were a promising indicator of the system’s potential. Finally, providers were willing to adopt and enhance the tool, even among those who were initially skeptical (Box 1).

Conclusion: Overall, our experience at implementing a patient-centered microblog to improve care team communication has been positive. Although intervention unit leadership supports its use, overall adoption has been variable so far. In instances when the system has been used, the perception of its value to coordinating the plan of care among care team members has been favorable. Our next steps are to continue to promote adoption and consider how to sustain and expand scope of use as our institution transitions to a vendor-based electronic health record.

Box 1: Comments and Feedback from Providers

“I was skeptical about using this tool at first, but after using it, I am a convert. It keeps all the messages about the patient in one place, not interspersed with email in my inbox. I changed the care that my patient received.” – A hospitalist attending

“I think it has a lot of promise. Can see it being very nice for keeping PCPs up-to-date with the smaller details… It is easy enough to read a discharge summary, but some of the details get lost.” – A primary care physician

“I was a consultant but rotated off after a week….it would be nice to have a button on the bottom of the message saying ‘Remove Me’” – A subspecialty consultant

Using a Software Program to Support Shared Decision Making about Participation in Breast Cancer Clinical Trials

Prudence Dalrymple, PhD, MS, Lisl Zach, PhD, Michelle Rogers, PhD
Amy Leader, DrPH, MPH, Tiffany Avery, MD, MPH, Anna Quinn, MPH, Anett Petrich, RN, Massimo Cristofanilli, MD, Russell Schilder, MD, Ronald Myers, PhD
1College of Computing & Informatics, Drexel University, Philadelphia, PA;
2Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA

Introduction

In the United States, over 230,000 women will be diagnosed this year with invasive breast cancer, resulting in about 40,000 deaths. Although treatment advances depend on clinical trials, numerous barriers to participation exist and interventions to promote informed, shared decision making may increase trial participation. We report on the use of an online decision support tool based on Analytic Hierarchical Processing to help breast cancer patients and their physicians make more informed decisions about trial participation.

Methods

Prior to an appointment with their oncologist, eligible patients meet a health educator and complete a baseline knowledge survey about clinical trials. Together, they review a one-page grid comparing risks and benefits of trial participation; they then use the online Decision Counseling Program (DCP) to elicit the patient’s preferences about trial participation. The patient expresses her top 3 reasons “pro” and “con” participation and rates their importance. The factors and their rating are entered into the DCP; the algorithm calculates a preference score from 0.000 to 1.000 and then produces a one-page summary report (SR) (see Figure 1). The patient takes the SR to her doctor’s appointment where trial participation is discussed. At 30 days, a telephone survey assesses the patient’s enrollment status, satisfaction with decision-making, and perceptions of the decision counseling session. The clinician documents trial enrollment.

Results

To date, 19 patients have enrolled in the study. “Pro” factors (36) included learning of new treatment options and believing that participation could benefit others. “Con” factors (19) were fear of unknown side effects and concern about managing trial logistics. The mean decision preference score was 0.6742 (SD=0.1465). Categorical assessment showed that one patient did not favor participation, 3 were equivocal and 15 favored participation. Eleven of the 19 patients have completed an endpoint survey at 30 days (5 were lost to follow-up and 3 are not yet due). Patient knowledge increased an average of 1 point, from 7 correct answers at baseline to 8 correct at endpoint. Ninety day chart audits indicate that trial enrollment has increased from an historical rate of 10% to a rate of 30%.

Discussion

The decision counseling process--preference clarification plus education--prepares patients and clinicians for shared decision-making by presenting the patient’s current attitudes and beliefs in a consistent format in the clinical workflow. These features address issues that have been problematic in other studies. Although this study focuses on cancer, the DCP can be adapted to other clinical situations. Furthermore, the DCP aggregates patient responses in an online database that allows researchers to identify the most frequent and important factors; these data can be extracted and analyzed to determine patterns in subpopulations. Additional research is needed to examine the characteristics of patient-provider communication to examine its effect on shared decision-making.

Conclusion

By supporting the patient through education and clarification of preferences and values, the DCP provides a supportive tool that appears to reduce decisional conflict and increase satisfaction while advancing the twin goals of shared decision-making and patient empowerment.

An EHR-Integrated Shared Decision Making Mobile App for Prostate Cancer Screening

Frank C. Day, MD, MPH, Majid Sarrafzadeh, PhD, Stephanie Smith, MPH, CPHQ, Mohammad Pourhomayoun, PhD, Costas Sideris MSc, Amogh Param MS, Jonathan Ben-Hamou BA, Deidre Keeves, PT, Michael A. Pfeffer, MD, Douglas S. Bell, MD, PhD  University of California, Los Angeles, CA

Introduction

Engaging patients in shared decision making (SDM) is important to optimize patient-centered outcomes and help control health care costs and patients who use SDM decision aids have had superior outcomes. Electronic health record (EHR) patient portals do not enable patients and families to engage in SDM, a difficult, time-consuming process. To do SDM, a patient needs a clear comparison of the likelihoods of benefit and risks of harm associated with each option, and guidance to the choice most congruent with the patient's values and preferences. Quantitative risk comparison is difficult because the concept of probability is hard to understand, particularly for outcomes that are binary in any individual. A large RCT to evaluate a SDM web app (with visual risk comparison diagrams to convey the risk tradeoff inherent to the PSA screening decision for prostate cancer) found patients' ratings of SDM did not differ between groups, but the app did positively affect the quantity and content of SDM discussions that physicians subsequently had with their patients. A mobile app will read EHR data (to generate risk diagrams based on the documented race and family history of prostate cancer), and write data in real-time to the EHR based on a patient's inputs (activation level, updated risk factors, values selections, and decision preference).

Methods

A multidisciplinary team (including patient advisor, health IT, computer science, and vendor technical services) is producing a mobile app/EHR integration with machine learning (ML) analytics. Our timeline (Mar 2014 – Nov 2015) includes the adaptation of a web-based SDM app to a mobile platform, establishing the architecture for secure data exchange that complies with privacy regulations and maintains data integrity, and limited usability testing with live patients. The target population is 55-69 year old men, who will use the app in primary care clinic and at home. Outcome measures will include usability and ML metrics. Multiple ML methods (e.g. support vector machine, decision trees, naive Bayes) will be analyzed for best fit of an expected ~300 dimension space (measured and derived from EHR, location and social media data) hyperplane to predict outcome variables (which patients specify a decision preference, which preference is specified, and whether preferences are congruent with subsequent medical management).

Results

Having committed support from the health system and a dedicated project management expert is key to overcome the numerous challenges with a project of this scope and timeline. Continual emphasis on both improving patient-centered care and maintaining data integrity, security and privacy is critical to maintain the alignment of goals for a diverse set of teams. Constraining the EHR interface to 9 data elements, and adapting a preexistent web app with established efficacy (that requires minimal new content development for a mobile platform) enables the team to focus on the data security, regulatory and policy/governance issues that arise with an early mHealth initiative. IRB approval provides the expectation of outcomes data and can be an effective driver to prioritize the allocation of necessary human resources.

Discussion

Secure bidirectional data exchange with an EHR is feasible and may increase patient engagement and improve patient-centered outcomes (AI–II.B: Clinical decision support and guideline systems). A ML algorithm may find unexpected predictors of optimal SDM outcomes within EHR, location and social media sources (FI–I.B: Social Media and mobile technology (mHealth)).

Polychromatic X-Ray Absorptiometry to Quantify Breast Density Volume, Ratio and their Associated Breast Cancer Risk in Full-Digital Mammography

Luis de Sisternes, PhD, \(^1\) Joseph H. Rothstein, MS, \(^2\) Abra M. Jeffers, \(^3\) Weiva Sieh, MD, PhD, \(^2\) and Daniel L. Rubin, MD, MS, \(^1,4\)

\(^1\) Department of Radiology, \(^2\) Health Research and Policy, \(^3\) Management Science and Engineering, and \(^4\) Medicine, Stanford University, Stanford, CA, USA

1. Introduction

Mammographic density, which refers to breast tissues other than adipose tissue (like epithelial or stromal tissue), is one of the strongest cancer risk factors\(^1\). Several area-based\(^2\) and volume-based\(^3,4\) approaches to quantitate breast density have been widely used. As screen-film mammography is being replaced by full-digital mammography (FFDM), existing methods originally described for digitized film mammograms were adapted to FFDM and many other are emerging given the easier implementation of advanced applications in a digital setting.

The semi-automated, area-based Cumulus approach has been reported to have the strongest cancer risk predictive ability\(^5\) in FFDM images, although it is limited by intra- and inter-reader variability in establishing a threshold for differentiating dense from surrounding fatty tissue. Our aim is to develop a novel, fully automated method to provide direct dense tissue measurements presenting higher association with cancer risk than Cumulus, while also eliminating any subjective judgement in such measurements. Our method is based on polychromatic X-ray absorptiometry (PXA), nonlinear programming, and image processing techniques to estimate dense volume and ratio of dense to adipose tissue on a pixel-by-pixel basis throughout FFDM images. We evaluated its ability to predict breast cancer risk, and compared it to Cumulus dense area and percent density (PD) measurements.

2. Methods

The idea behind our proposed method is based on single energy X-ray absorptiometry\(^6\), but taking into account the fact that the mammogram is produced by a polychromatic X-ray source (we do not assume a monochromatic source). The method does not require a phantom in the acquired images. Following the well-known Beer-Lambert law and assuming that breast is mainly composed of adipose and dense tissue, the raw intensity values recorded at the detector can be expressed in the terms shown in Figure 1. This expression can be solved for the ratio of adipose and dense tissue at each pixel location using a constrained non-linear optimization technique\(^7\), where the energy-dependent attenuation coefficients of each tissue type are known\(^8\), the source spectrum is simulated\(^9\), and breast thickness can be estimated in a similar manner as in de Sisternes et al\(^10\). Two overall measurements were computed from the pixel-by-pixel estimation: (1) absolute PXA dense volume, computed by adding pixel by pixel the result from the multiplication of dense ratio and breast thickness; (2) PXA volumetric percent density (VPD), computed by averaging the pixel-based dense ratio values throughout the mammogram, weighted by breast thickness.

We evaluated our methods in 131 mammograms from unaffected breasts prior to a cancer diagnosis in the contralateral breast (cases) and 239 mammograms from healthy women without breast cancer (controls). Control women were chosen to match the case patients by age and race. Patient demographics are summarized in Table 1. The study protocol was approved by the Stanford University Institutional Review Board. Cumulus dense area and PD values were collected by an expert user of the software for comparison to those produced by our methods.

3. Results

We compared the distribution of patient demographics, Cumulus and PXA measurements in case and control women by computing false discovery rate adjusted q-values (Table 1). Table 2 summarizes the odds ratios (OR) estimated for the two methods as quartiles (defined among controls) and as continuous variables (in SD increments), unadjusted and adjusted for age, BMI, race and menopausal status. We computed the area under the receiver operating characteristic curve (AUC) for each method to compare their ability to discriminate between cases and controls. Overall, slightly higher associations with breast cancer risk were observed for our proposed method.

4. Discussion

Both Cumulus and PXA measurements were positively associated with breast cancer risk, with the strongest continuous association observed for each SD increment of PXA VPD. Women in the top quartile of PXA VPD had 5.30 (1.99 to 14.16) times the risk of women in the bottom quartile. PXA measurements were fully automated and not operator-dependent, eliminating any possible subjective variability. Although a highly-trained reader generated the Cumulus measurements, reader judgement may have contributed to their slightly weaker associations with breast cancer risk. PXA measurements also showed a slightly greater ability to discriminate between cases and controls in terms of AUC. These AUC values were low (0.64 for dense volume and 0.65 VPD), but similar to that previously reported by others, indicating its limited value in individual cancer risk prediction. Therefore, the PXA method presented here appears to be a valid automated alternative to the labor-intensive semi-automated Cumulus approach for quantifying breast density when raw FFDM images are available for analysis, and it also offers the possibility of pixel-by-pixel analysis of volume-based methods. These quantifications, alone or jointly with other risk factors, might be useful to stratify women in the population according to risk for tailored screening or interventions.

Characterizing the Frequency of Pharmacogenomic Biomarker-Guided Prescribing for Drugs with Pharmacogenomic Biomarker information in the FDA Labelling: A Pilot Study Using Data from an Electronic Health Record

Beth Devine, PhD, PharmD, MBA1,2,3, Maher Khelifi, PharmD2, Katelyn Keyloun, PharmD1, Nathaniel Hendrix, PharmD1, Patrick Mathias, MD, PhD4, Christian Bock1,4+, Peter Tarczy-Hornoch, MD, FACMI1,4,6

1Pharmaceutical Outcomes Research and Policy Program; 2Department of Biomedical Informatics and Medical Education; 3Department of Health Services; 4Department of Laboratory Medicine, 5Department of Pediatrics, Division of Neonatology; 6Department of Computer Science and Engineering, University of Washington, Seattle, WA, USA

*(now University of Heidelberg, Germany)

BACKGROUND
Based on self-report, approximately 39% of United States-based physicians obtain pharmacogenomic (PGx) testing information from drug labelling. However, physicians may broadly underutilize this information to guide practice.1 The recent large-scale availability of clinical data from electronic health records (EHRs), coupled with the rapid decrease in the per-test cost of genotyping, and the capability of advanced clinical decision support systems to guide therapy, make the investigation of PGx-guided prescribing in real-world settings an area of research that is now feasible and timely. The objective of this pilot study is to use clinical data from the EHRs and other clinical systems within the University of Washington Medicine system (inpatient and outpatient), to estimate and characterize PGx biomarker use, assess the association between characteristics of PGx-med pairs and the use of PGx tests, and estimate the temporal association between medication prescribing and PGx testing.

METHODS
Using our institutional clinical data warehouse, we extracted data from 2 EHRs and an organization-wide laboratory information system from January 2010 through March 2014. We identified patients ≥ 18 years of age who had an incident, index prescription (for outpatients) or medication administration event (for inpatients) for the medications which contain a drug label the includes a recommendation for PGx testing. By linking laboratory data with index medication events, we estimated the frequency of associated PGx-biomarker testing for this group of medications, and established the temporal association between each medication order and PGx testing order. In addition, we examined the medications with the highest proportion of PGx testing to examine differences by therapeutic area.

RESULTS
The patient cohort consists of 188,783 patients who each received one or more of 137 medications that correspond with one, one or more of 47 distinct PGx biomarkers, which together constitute 155 PGx-med pairs. The dataset captures 408,603 index prescriptions (outpatient) or medication administration events (inpatient) and 22,441 PGx tests. Across all eligible index prescriptions in the study period, 0.9% were associated with a PGx test, with an increase from 0.77% of index medications in 2010 to 1.12% in 2013 (Figure 1). Greater than 50% of PGx tests were performed within 60 days of the index medication prescription/administration (Figure 2). The top 25 most frequently prescribed/administered medications accounted for 81% of index medications but only 0.3% of such events had an associated PGx test performed. Oncology medications accounted for 17 of the top 20 medications (85%) with the highest rate of associated PGx testing (Table 1).

DISCUSSION
By integrating data from multiple EHRs and other clinical systems, we examined over 400,000 eligible medication prescriptions and administration events. We determined that <1% had a corresponding PGx biomarker test, and the low overall percentage was driven by frequently ordered medications such as omeprazole or simvastatin that rarely had an associated PGx test performed. Over the 4 full years covered by the study, the use of PGx testing has increased with time. A majority of the PGx tests we captured were performed within 2 months of the index medication event. As expected, oncology medications represented a significant majority of the top 20 medications with the highest proportion of associated PGx testing. Our study informs the field of PGx biomarker use by providing an estimate of the frequency of use in real-world clinical practice, enabling investigation of the characteristics of PGx-med pairs most frequently associated with biomarker use, and estimating the temporal association between incident medication use and biomarker testing.

2 Years Later: Follow-up to Analysis of Electronic Medication Orders with Large Overdoses

Judith W Dexheimer, PhD, Eric S Kirkendall, MD, MS, Michal Kouril, PhD, Thomas Minich, BSpH, Philip Hagedorn, MD, Cecilia Mahdi, MBA, S. Andrew Spooner MD
Cincinnati Children’s Hospital Medical Center (CCHMC), Cincinnati, OH

Introduction

A major challenge facing pediatric medicine is the management of weight-based dosing rules in electronic health records (EHRs). EHRs implement rules supplied by third-party vendors to help guide the dosing process. Since many of these rules are conservative, they result in noisy alerting, and are therefore overridden by users. EHR implementers typically customize these vendor-supplied rules to reduce this noise. In a previous report, we examined users’ responses to large overdoses and characterized user-CPOE actions associated with these large overdoses. In this paper, we provide an update to our original manuscript with 24 months’ additional data. We track the original trends and how well our medication rules are performing.

Methods

Cincinnati Children’s Hospital Medical Center (CCHMC) is a 587-bed, freestanding, academic, pediatric medical center with more than 1.2 million patient encounters annually and over 800 faculty members. It has over 30,000 admissions, 33,000 surgeries, 900,000 ambulatory encounters, and 125,000 emergency department visits per year. CCHMC uses an enterprise EHR system from Epic™ (Verona, WI), initially configured to use the Medi-Span database that includes dosing rules (Wolters Kluwer Health, Philadelphia, PA). The CCHMC pharmacy team customizes these rules per local dosing guidance. Up to 80% of alerts are triggered by customized rules (Figure 1). There are approximately 28,684 medication orders written monthly; approximately 87% of the alerts related to these medications are overridden at the time of ordering (Figure 2). Of these, approximately 5,831 are non-filtered single-dose overdose alerts seen at the order-entry phase; 90% of these are overridden. We focused on large (≥500% of the maximum rule-based dose) overdoses. We assume that if a user cancels the ordering session after seeing the alert dialog box, it is likely that the user cancelled the orders because of one of the presented alerts, so we define alert salience as the number of orders associated with an alert cancellation divided by the total number of alerts presented.

Results and Discussion

As the result of regular modification of dosing rules over several years, we have seen a decrease in the number of alerts shown to users. The updated data are shown in figures 2-4. We have also seen a decrease in % of all orders that had a single dose overdose alert by 3% from a peak of around 10% to roughly 7% (Figure 1). With this decrease in large overdose alerts (Figure 3), we have seen an increase in alert salience (Figure 4). An example of the increased salience of alerts as a result of rule modification is illustrated in figure 4 for clindamycin. The user burden
for alerts in our system is small (8% of orders) (Figure 3). Over the course of tailoring alert parameters, we have seen this burden fall from 10% to 7%. We have evidence to suggest that decreasing this alert burden increases salience.

**Figure 2.** Medications with >= 500% overdose alerts.

**Figure 3.** Order Alert Rates in enter orders.

**Figure 4.** Salience rates for single dose over dose alerts and for medications with >=500% overdose rates.

Completeness and Timeliness of Notifiable Disease Surveillance Data 
Submitted by Providers to Public Health Authorities 

Brian E. Dixon1,2, Patrick T.S. Lai3, Uzay Kirbiyik1, Zuoyi Zhang2, Debra Revere4, Rebecca Hills4, P. Joseph Gibson5, Jennifer Williams2, Shaun J. Grannis2

Fairbanks School of Public Health, Indianapolis, IN; 2Regenstrief Institute Center for Biomedical Informatics, Indianapolis, IN; 3IU School of Informatics and Computing, Indianapolis, IN; 4University of Washington, Seattle, WA; 5Marion County Public Health Department, Indianapolis, IN

Introduction
Surveillance is the cornerstone of public health practice. Traditionally, health departments have relied on passive reporting of communicable and infectious diseases by hospital, laboratory and clinic staff to public health authorities. However, passive approaches are known to be burdensome for reporters, producing incomplete and delayed reports which can impede assessment and potentially delay recognition of patterns and outbreaks.

Increasingly, surveillance practice is shifting toward greater use of electronic receipt of disease information. The adoption of electronic health record (EHR) systems and health information exchange (HIE) among clinical organizations, driven by policies like the ‘meaningful use’ program, is creating an information infrastructure that public health organizations can leverage. Data from the U.S. Office of the National Coordinator for Health Information Technology indicate that health departments receive up to 62% of their total laboratory-based reports for notifiable diseases by electronic transmission (1). Although provider-based reporting continues to be paper-based, EHR systems and HIE networks provide a framework for electronic submission of treatment, corollary results, and other details not available from laboratory information systems.

Methods
We are conducting a controlled trial of an informatics intervention designed to improve the completeness and timeliness of provider-based information to public health authorities for notifiable disease cases. Our study occurs in the context of the Indiana Health Information Exchange (IHIE), a large, robust HIE network that delivers clinical results to over 25,000 physicians. Using components within the IHIE information infrastructure, including the Notifiable Condition Detector, our intervention is pre-populating the official Indiana State Department of Health communicable disease reporting form (paper) with patient demographics, notifiable disease confirmatory test results, and provider information using ELR data. The pre-populated form is delivered electronically to the provider using the HIE for review and completion. A process that previously began with a human in the clinic noticing a result which should be reported to public health then completing a blank, paper form that was eventually faxed to the local health department. A detailed description of the study protocol was described previously (2).

The study focuses on seven representative diseases (Salmonella, Hepatitis C, Hepatitis B, Chlamydia, Gonorrhea, Syphilis, Histoplasmosis) commonly investigated by local health department staff. Like most states, Indiana utilizes a dual-reporting structure: mandatory case reporting by providers and reporting of test results by laboratories. Prior to deploying the intervention, we gathered baseline reporting information from fax and paper notifiable disease reports submitted by both providers and labs to the Marion County Public Health Department. The time period for collecting data varied based on disease prevalence. We gathered reports for more prevalent diseases (e.g., Chlamydia) over a three-month period (May to July 2012), while reports for less prevalent diseases (e.g., Histoplasmosis) were gathered over two years (2010-2012). We similarly gathered electronic laboratory reports for the same conditions within the same timeframe from the NCD within the IHIE infrastructure.

Key information, that which is used by the health department to initiate case investigation, was abstracted from each report and collated by disease. We evaluated the completeness of reporting data elements for paper, fax-based, and electronic lab reports sent from providers and labs using methods previously described in prior work on just electronic lab reports (3, 4). Timeliness (elapsed time) was measured using the difference in number of calendar days between the date of the positive lab result and the date which the report was submitted to the first public health authority (local health department or state health agency).

Results
A total of 12,098 reports representing 8,353 unique patients provided the baseline dataset. Providers submitted 2,740 paper/fax reports for 2,314 patients; labs submitted 1,447 paper/fax reports for 1,134 patients; and labs submitted
7,911 ELRs for 6,294 patients. Some patient files (N=2,450) included multiple, duplicate reports from providers and/or labs. For example, in some cases both the infection control staff at a hospital and the patient’s primary care provider submitted a report. Table 1 describes the completeness of data fields on paper, fax-based and ELR reports of notifiable diseases.

Discussion

Completeness of data in notifiable disease reports is heterogeneous. In general ELR data are more complete than paper- and fax-based reports from labs and providers, with the exception of provider contact information which is more complete in faxed lab reports and ethnicity which is more complete in provider reports. Interestingly, lab-based reports often contained more complete provider contact data than documents submitted from clinics and infection control. With respect to timeliness, the mean difference in days for ELR is superior to both faxed-based lab and provider reports. The results are similar to our prior analyses involving ELR data sources (3-5).

Completeness patterns call into question the need for dual-reporting laws in states that require both providers and labs to report the same information to public health for accurate surveillance of notifiable diseases. Laboratory data sources possess unique strengths with only minor weaknesses. Given that EHR and HIE systems are increasingly interfaced with health departments for ELR to achieve the aims of the meaningful use policies, there is an opportunity to supplant manual, paper-based processes with enhanced data from integrated electronic data sources. This could be a victory not only for health departments who desire more complete and timely data but also providers who find public health reporting processes time-consuming and challenging given competing priorities.

Pharmacy drug dispensing after physician discontinuation (cancel) orders

Tewodros Eguale, MD, PhD1,2,3,4, Aman Verma, PhD4, Enrique Seoane-Vazquez, PhD1,2, Rosa Rodriguez-Monguio, PhD5, David W. Bates, MD, MSc2,3, Robyn Tamblyn, PhD4 and Gordon D. Schiff, MD2,3

Background: Physicians discontinue previously prescribed drugs due to considerations of safety, effectiveness, and cost, but it is unclear what effect these discontinuation orders have on pharmacy dispensing. New electronic health records (EHR) allow us to monitor discontinuation orders, discontinuation reasons, and actual dispensation data.

Objectives: Using data from an EHR, we assessed the frequency of pharmacy drug dispensation after physicians discontinue orders, and modeled how the discontinuation reasons affected pharmacy dispensation.

Methods: We conducted the study in two Canadian cities where family physicians use the MOXXI EHR, which allows physicians to prescribe and discontinue drugs and send the information to the pharmacy. We included all discontinuation orders issued between 2005 and 2012 for patients fully covered by provincial drug insurance. Using logistic regression, we modeled pharmacy dispensation of discontinued drugs within 12 months of the discontinuation order as a function of the discontinuation reasons, and patient and drug characteristics.

Results: Between 2005 and 2012 there were 40,452 drug discontinuation orders, of which 7,325 (18.1%) were dispensed within 12 months (75% within the 1st month). Many drugs were discontinued because they were “no longer necessary” (27.3%), ineffective (18.7%) or caused adverse drug events (18.2%). Drugs discontinued due to adverse drug event [OR: 0.7 95% CI: (0.70.8)] and allergic reaction [OR: 0.6 95% CI: (0.41.0)] had low risk of dispensation compared to drugs stopped because they were “no longer necessary”, while drugs discontinued because they were ineffective had a higher odds [OR: 1.3 95% CI: (1.21.5)]. Compared to gastrointestinal drugs, central nervous system drugs [OR: 1.5 95% CI: (1.31.6)] and cardiovascular drugs [OR: 1.1 95% CI: (1.01.2)] had higher odds of dispensation and anti-infective drugs had lower odds [OR: 95% CI: 0.5 (0.40.6)].

Conclusions: Patient safety may have been compromised when discontinued drugs were dispensed to patients, especially those discontinued due to an adverse drug reaction. The next generation of electronic health records should better integrate with the pharmacy, to avert dispensation of discontinued drugs and curb cost to the patient and the payer.
Computer-Mediated Intervention to Improve Medication Literacy in Seniors with Diabetes Results in Better Patient-Reported Outcomes and Glycemic Control

Joseph Finkelstein, MD, PhD, McKenzie E. Bedra, MPH
Chronic Disease Informatics Program, Johns Hopkins University, Baltimore, MD

Abstract

The purpose of this study was to compare interactive continuous patient education (iCOPE) to a brochure in a randomized controlled trial. Older adults taking oral diabetes medications were randomly assigned to receive the same diabetes medications curriculum via iCOPE or printed brochure combined with periodic reminders. At 3 months significant improvement in medication knowledge, self-efficacy and glycemic control was found in the intervention group whereas changes in the control group remained not significant.

Introduction

Low medication literacy was shown to be prevalent in older adults and to negatively affect quality of life and clinical outcomes. Ongoing patient empowerment addressing medication literacy results in patient activation and improved health outcomes. Interactive health communication technologies have been shown effective in promoting health education and improving medication literacy, however, its potential in older adults has not been uncovered systematically.

Methods

Interactive continuous patient education (iCOPE) system was used to deliver medication literacy intervention via touch screen tablet computers using personalized avatar-based interface. The platform supports continuous patient engagement and empowerment driven by adult learning theories as previously described [1]. Eligible participants included older adults who were 65 years of age and older, currently taking or have taken an oral diabetes medication in the past, and had a Mini Mental State Examination score of at least 23 [1]. The study subjects were randomly assigned to receive the same curriculum via iCOPE or a printed brochure. The enrolled participants were asked to complete the oral diabetes medication curriculum within 24 hours at their own pace. During 6-month follow-up, patients in the intervention group periodically received interactive engagement materials via e-mail or text messages whereas the patients in the control group received printed materials via mail on a regular basis. The participants were assessed at baseline, 24-hr, 1-mm, 3-mm, and 6-mm visits using established questionnaires reflecting medication literacy, self-efficacy, quality of life and self-management skills. In addition, HbA1c was measured at each visit but 24-hr. Socio-demographic background, disease history, health and computer literacy were collected at baseline.

Results

Overall, 101 older adults were randomized to intervention and control groups with no differences at baseline; 59% were females and the average age was 75; 81% responded that the tablet education was not difficult to use, whereas in the control group 59% reported the sentences used in the educational materials were difficult. At 3 months significant improvement in medication knowledge, self-efficacy and glycemic control was found in the intervention group whereas changes in the control group remained not significant (Table 1). There was a threefold difference in mean knowledge score increase (6.5±5.8 vs. 2.0±3.4) and 4-fold difference in mean HbA1c decrease (-0.41±1.24 vs. -0.13±1.48) between intervention and control groups at 3 months compared to baseline (Figure 1).

Discussion and Conclusion

Education via a touch screen tablet resulted in knowledge gains. Continuous patient engagement and empowerment delivered via interactive mobile tools is effective means to improve medication literacy in older adults with diabetes.

Figure 1. Mean outcome change over time.
Feature Selection Based LapSVM to Classify Medical Event Reports and Enhance Patient Safety

Samah Jamal Fodeh, PhD¹, Cynthia Brandt, MD MPH², Perry Miller, MD, PhD³, Michele Koss RN⁴, Andrea Benin, MD⁵

(¹-⁴) Yale University School of Medicine, Yale University, New Haven, CT, 06520
(⁴,⁵) Connecticut Children’s Medical Center, Hartford, CT

Introduction. Timely reporting and analysis of adverse events and medical errors is critical to driving forward programs in patient safety. Due to the large numbers of event reports accumulating daily in health institutions, manually finding and labeling certain types of events needs to be replaced with automated classification methods. In semi-supervised learning, methods usually utilize unlabeled data in addition to labeled data to perform a certain classification task. In this work we propose feature based Laplacian support vector machine (FS-LapSVM) to identify two major error events: patient mismatches errors and patient weight errors.

Problem. Event reporting systems rapidly accumulate incident reports, therefore the manual review of the reports became very challenging and prohibitively resource-intensive. Although most reporting systems provide a coding system for classifying major patient safety events, labeling a report using the coding system remains a subjective matter determined by the person documenting the report which results in inconsistency in how reports are classified. Also, coding systems do not necessarily provide a match to the event to be classified. One alternative to address these issues is to automatically classify event reports by exploiting their narratives using text-based classification from machine learning. While classification has been successfully used to detect AE in the EHRs, its utility has been relatively unexplored on event and medical error reports.

Methods In semi-supervised learning, a classification function is estimated using labeled and unlabeled data. We propose FS-LapSVM; a hybrid method that combines F-score feature selection [1] with Laplacian support vector machine [2]. Although many feature selection approaches have been combined with LapSVM, the F-score selection approach has not been tested before with LapSVM. We labeled (~9000) reports that we extracted from Quintros reporting system at Connecticut Children’s Medical Center. The labeled reference standard contained 1102, 85 reports of patient mismatches and weight errors respectively and the remaining reports were assigned the category “other”. Because LapSVM utilizes labeled and unlabeled reports, for each event category, the sample included three types of reports: (1) labeled reports from the category to be detected, (2) equivalent number of records from the “other” category and (3) unlabeled reports equivalent in size to 15% of both categories.

Results: With 20% reduction of features, Table 1 shows that FS-LapSVM classifier outperformed standard LapSVM in classifying patient mismatch across all metrics on the validation set. Superior performance of FS-LapSVM finding weight error reports was observed compared to LapSVM; an increase of 10%, 5%, 5% in terms of PPV, F-measure, and accuracy, respectively when the respective models were evaluated on the validation set.

Table 1: Performance comparison between FS-LapSVM and LapSVM

Conclusions. We demonstrate the utility of FS-LapSVM which we utilized to identify two important events: patients’ mismatches and weight errors. FS-LapSVM can effectively decrease the size of the feature set and achieve better results compared to LapSVM. Next, we will explore the effect of adding more unlabeled data on performance.

Developing a Collaborative Evaluation Framework for Utah’s APCD

Jennifer H. Garvin, PhD, MBA, RHIA1, 2, 3, Kristina Doing-Harris, PhD1, Jonathan H. Cardwell, MS1, Kailah Davis, PhD4, Charles Hawley, MA4, and Wu Xu, PhD1, 2, 4, 1Department of Biomedical Informatics, 2Division of Epidemiology, University of Utah, Salt Lake City, UT; 3VA Health Care System, Salt Lake City, UT; 4Utah Department of Health

Abstract: We developed an evaluation framework based on a collaborative evaluation model for a large-scale, federally-funded information system improvement project with the Utah Department of Health. In this presentation, we describe the development of the framework and its elements, all of which form an essential foundation with regard to the objectives of Utah’s All Payer Claims Database (APCD) as well as process evaluation results.

Introduction: The overall goal for the Cycle III grant is to improve the Utah All Payers Claims Database (APCD)1 by developing analytic capacity and producing online pricing/cost transparency reports for consumers, employers, researchers, and the general public in Utah. In order to facilitate success for this large-scale APCD implementation, we chose a collaborative evaluation model that paralleled the project management process chosen by the APCD principal investigator2. We present the results of the evaluation at year which relates to processes used. Evaluation of use cases will occur in year 3. Prior APCD development efforts did not include collaborative evaluation methods.

Methods: Development of the evaluation framework began by identifying our process of change, which brings the entire evaluation program to a concise focus. Once identified, evaluation questions were formed to support that process of change, delineating what, when, who, and how the data will be collected until each evaluation question has been answered. Logic models are also developed collaboratively with project groups. This collaborative process between the project groups and evaluation team set a foundation from which to monitor and evaluate the attainment of the project’s objectives and facilitated the use of evaluation data by the project teams. Evaluation components were shared and iteratively developed with project groups via email and meeting presentations.

Results: Through a total of 71 communications with 16 project groups, we determined our evaluation plan. During this iterative development we also determined key use cases to drive improved APCD data quality, new health information technology development, and analytic capability expansion using a total of 274 communications. The ability to undertake uses cases will be assessed in year 3. During year 1 and 2 we evaluated the use of components of best practices for improving claims data quality, large-scale health IT (HIT) development, healthcare information security and privacy, and software development. As reflected in Table 1, there was significant and increasing use of component parts of best practices. We also used logic models with each team.

Conclusion: Our collaborative evaluation framework was instrumental in the development and success of Utah’s APCD implementation to date. The framework elements, such as best practices, are foundational to the support of the use cases and are essential to accomplishing the project’s objectives. Collaborative program evaluation processes provided additional data, processes, and value to facilitate successful completion of the project. The evaluation process will benefit stakeholders by improving online pricing/cost transparency reports for consumers, employers, researchers, and the general public in Utah.

Acknowledgements: We thank the stakeholders and members of the Utah Cycle III project team for their engagement with the program evaluation team. This publication is funded by CMS Grants to States to Support Health Insurance Rate Review and Increase Transparency in Health Care Pricing, Cycle III [Grant Number: 1 PRPPR140059-01-00], through a subcontract with Utah Department of Health Office of Health Care Statistics.

**Introduction**

Clinical decision support (CDS) is becoming an increasingly important component of health care designed to improve the clinical processes and outcomes of care (1). While much has been written about CDS targeting physicians’ decision making (2, 3), comparatively less is known about the outcomes for CDS targeting nurses, particularly for bedside acute care nurses (4, 5). In this abstract, we report on our preliminary results of an integrative review of studies regarding CDS for acute care bedside nurses.

**Methods**

We conducted a comprehensive integrative review (6) of published research articles on the design and evaluation of nursing CDS. To avoid overlap with previous reviews, we included articles published from 2006-2013. Our search strategy included original studies identified across 6 databases (CINAHL, EMBASE, IEEE Explorer, MEDLINE via PubMed, Scopus, and Web of Science). We used the following subject headings and key words: computer-assisted decision making, computers, clinical decision support systems, expert systems, information systems, hospital, nursing informatics, nursing homes, nursing staff, reminder systems, and derivatives of the word, “nurse”. Inclusion criteria included: peer-reviewed articles, focused on nursing decision support in an acute care settings. Exclusion criteria included: conference proceedings, articles without exclusive focus on RN (Registered Nurse)-directed decisions, CDS that was not computerized, non-acute settings, or included RN’s in combination with other clinicians. A structured data form and definitions including purpose, methods, study design and outcomes, and integration with Electronic Health Record (EHR) was developed for data abstraction and used for data analysis.

**Results**

Our search yielded 2477 unique articles that were systematically reduced to 28 articles that met the inclusion criteria (see Figure 1). Inter-rater agreement was established at 89-91% across the steps of review and data abstraction. Of 28 articles included, randomized controlled trials (n=1), quasi-experimental (n= 11), single correlational (n= 4) and single descriptive or qualitative (n=12) were identified. The purposes of CDS in acute care nursing was most often to enforce guideline adherence (36%), and support nursing diagnostic decision making (36%). Less often, CDS was used to support medication dosing with algorithms, situational awareness and emergency triaging. CDS was integrated into the EHR less than a third of the time (32%) and most often required manual entry of data (54%). Studies of CDS for pediatrics and obstetric populations were absent.

The most common outcomes measured were process outcomes (79%). These included accurate interpretation by nurses of CDS information (25%), accuracy of CDS information (29%), situation awareness (32%), workload (21%), efficiency (21%) and errors (18%). Thirteen of the 22 studies measured >1 process outcomes. Four studies reported statistically significant improvements in processes; two for nurse accuracy and two for efficiency. Assessment of usability outcomes was also common (68%), including 4 types: global usability (21%), learnability (29%), subjective satisfaction (14%), and value/usefulness (32%). Statistically significant improvement was found in 14% of the studies measuring usability. The least common outcomes measured were patient outcomes (18%), of this small group of studies only two demonstrated statistically significant patient improvement.

**Discussion/Conclusions**

While CDS targeted to nursing decisions hold promise for improving patient care, this review found statistically significant improvement in outcomes in only 40% of the studies. Process measures improved for 4 studies, usability improved for 5 studies and patient outcomes improved in 2 studies. There are several reasons for the relatively small number. First, 15 included studies reported only descriptive or qualitative results. Second, for patient outcomes, there were 14 studies in which patient outcome measurement was not applicable (e.g. lab based studies). For the lab-based studies, it is not clear if the CDS are now used in practice and therefore suitable for patient outcome measurement. In summary, for nursing CDS to deliver on the promise of improved care, research must progress beyond the lab stage and evaluate measureable patient outcomes using inferential statistics and more sophisticated study designs.
Figure 1. Records Selection Process

1. Title review: Not in English (28), conference proceedings (644), not exclusively focused on R.N.s (750), not healthcare related (50), and not inpatient acute care (305)

2. Abstract review: Not research (86), a review (17), students as the only subjects (9), not only RNs (133), not automated as health information technology (98), not CDS in its current form (154), or CDS was not patient care related (18)

3. Article Review: Not research (4), students were the only subjects (1), not exclusively R.N. focused (4), not health information technology (2), not CDS (4), or the CDS was not related to caring for patients (2)

Automating Guidelines for Clinical Decision Support (CDS): A Categorization of Knowledge Engineering and Implementation Decisions

Mary K. Goldstein MD MS,1, 2 Samson W. Tu MS,2,1 Connie Oshiro PhD,1 Susana Martins MD MSc,1 Dan Wang PhD,1 Amy Furman PharmD,1 Michael Ashcraft MD,1 Jonathan Mendoza,1 Paul A. Heidenreich MD MS1,2, Kaeli Yuen,1 1VA Palo Alto Health Care System, Palo Alto, CA; 2Stanford University, Stanford, CA

Introduction: ATHENA-CDS [1] is a CDS system developed at VA Palo Alto Health Care System and Stanford University. ATHENA-CDS has encoded complex clinical practice guideline recommendations from five clinical domains: hypertension, chronic kidney disease, heart failure, hyperlipidemia, and diabetes. As part of a project to deliver CDS to health professionals for VA patients whose data do not meet one or more performance measures, the CDS is being integrated into an existing clinical Dashboard that flags patients not meeting performance measures. In this study, we seek to validate and to extend the 13 steps Shiffman [2] identified for translating the knowledge contained in guideline text into a computable format and to integrate the information into clinical workflow.

Methods: We identified 119 decisions made at project meetings over an 8-month period. One project member, an experienced knowledge engineer, evaluated each decision to categorize the decisions into Shiffman’s steps, and, when such categorization was not possible, proposed new categories. A senior clinician evaluated the initial categorization and, working with the knowledge engineer, developed a consensus categorization of the decisions.

Results:

Discussion: Some of Shiffman’s steps, such as atomize, de-abstract, and disambiguate, are not reflected or are under-represented in ATHENA-CDS’s formally recorded decisions because project knowledge engineers perform them without requiring the whole team making decisions about them. A number of factors account for decisions that cannot be classified using Shiffman’s categories. First, ATHENA-CDS generates recommendations for patients who may have multiple co-morbidities, making interactions among guideline recommendations an important concern. Shiffman’s steps envision formalizing a set of recommendations within a system where the implementers can make their own decisions about such things as how to disambiguate concepts. In contrast, because ATHENA CDS is being integrated into an existing Dashboard, we have to take into account decisions that developers of the Dashboard have already made. We can also make use of data analytics (e.g., patients’ adherence to prescribed medications) that the Dashboard makes available. With the proliferation of health information technology (HIT) tools, this is likely to be a common scenario for CDS developers. ATHENA-CDS is implemented using a rich guideline model, not rules with decision variables that Shiffman assumes. Thus we have to make decisions about knowledge representation (e.g., how a domain ontology should be organized) that are not recognized in his methodology. Finally, ATHENA-CDS is a working system, not just an implementation specification that Shiffman’s methodology produces, making issues such as local adaptation, terminology mapping, testing, and project management important.

Conclusion: We validated and extended steps in Shiffman’s approach to making guideline recommendations computable. We identified additional knowledge engineering and implementation categories needed because of multiple comorbidities and guidelines, actual system implementation, and integration with existing HIT tools.

Abstract. There are over 126 billion functional genomics data points from more than 1.6 million digital samples in public functional genomics experiments amassed over the last 15 years. This highest-quality, NIH-funded functional genomics Big Data can be translated into large-scale drug and biomarker discovery as our lab and others have repeatedly shown. However, individual samples remain poorly described by unstructured free text that represents complex bio-ontologies that are shared by samples across independent experiments. Thus far, strictly computational approaches to annotate GEO en-masse such as text mining have largely failed to recapitulate biological annotations with any measured reliability. Therefore, to address this growing Big Data problem and to scale the precise annotation and useful interpretation of open digital samples, we previously built the Search Tag Analyze Resource (STAR; stargeo.org) to allow anyone to describe GEO sample phenotypes uniformly across different studies and to characterize gene expression signatures for disease. Here, we design and implement a validation system based on STAR annotations to reward concordance among expert inter-raters and converge on precision annotations at scale. Furthermore, we use meta-analytics across many thousands of samples with shared phenotypes to estimate a molecular nosology, or classification of disease, for over 20 different autoimmune, infectious, or neoplastic clinical conditions. Our innovative approach uses emerging Internet technologies such as crowdsourcing and social networks to translate open Big Data in biomedicine into structured knowledge that can be used at scale for massive drug and biomarker discovery.

Introduction. The NCBI’s Gene Expression Omnibus (GEO) is perhaps the largest of a number of public data repositories¹⁻³, and it currently shares the gene expression measurements of over 1.6 million samples drawn from functional genomics over the last 15 years.⁴⁻⁶. The term ‘crowdsourcing’ was first described in 2006,⁷ and it describes the process of breaking a complex problem into smaller ‘micro-tasks’ that engage a crowd of participants to jointly undertake. Crowdsourcing is rapidly being applied to bioinformatics problems that require human involvement⁸⁻¹⁰, and colleagues have had recent success in using crowds to annotate PubMed abstracts for mentions of disease and genes with non-specialized curatorsⁱ¹, while others have had mixed results making biological annotations on unstructured text with a naive or uninformed crowd.¹². We previously developed the Search Tag Analyze Resource (STAR) web application¹³ (http://stargeo.org) to leverage crowdsourcing among biomedical curators to annotating GEO.¹⁴ The STAR annotation process included a web interface for curators to design regular expressions (RegExs), a standardized syntax in computer science,¹⁵ to efficiently match and extract text, as shown in in Figure 1.

Figure 1: STAR annotation process. The flow chart shows how unstructured free text attributes from GEO are annotated by specialized curators across Tags. The crowd repeatedly makes multiple passes at the annotation until at least two independent experts agree. The figure also shows a screenshot of the STAR annotation process for Tagging the experimental study (GSE12351) entitled “Melanoma: comparison between common nevi, radial-vertical growth phase melanoma, metastases and dysplastic nevi”. The melanoma Tag is assigned a RegEx that maps unstructured ‘melanoma’ free text attributes to GEO sample descriptors. STAR automatically highlights matching samples based with by real-time RegEx search. Therefore, by entering only the unstructured text attributes that discriminates ‘melanoma from ‘common acquired melanocytic nevus’ as shown in this example, a curator can quickly annotate disease, outcome, phenotype or any other experimental qualifier. This process is repeated across different studies.
Methods. We reimbursed $10,000 to curators at a rate of 10c for every concordant sample annotated with 5c apiece going to each curator. We integrated reimbursement by electronic gift cards directly into the STAR web interface using the Tango Card (http://tangocard.com) API for access to over 70 retailers including Amazon, Wal-Mart, and Starbucks. We used meta-analysis performed by STAR to estimate a nosology for over 20 diseases whose annotations were crowdsourced by biomedical experts. For each gene across every disease phenotype, we calculated the significance of effect of that gene in disease as the inversely scaled estimate of statistical significance of the mean expression difference of cases and controls assuming a random effects model. We then used agglomerative clustering significance plot a dendrogram as a molecular classification for disease or nosology.

Results. We used Twitter to strategically recruit STAR curators that would be interested in learning about disease and defining genomic disease signatures by querying key words like “biomedicine”, “translational medicine”, “research”, etc. In 8 months, we have acquired approximately >485,000 annotations, and we have demonstrated high (>90%) precision among curators that cross annotated each others efforts (Figure 2). Current projections suggest that within three years we can achieve complete coverage of GEO data with at least one STAR annotation (Figure 3). Therefore, STAR crowdsourcing may be the only way to completely annotate GEO. We clustered all the diseases analyzed by the significance of their estimated meta effects over 11,267 genes that were measured across all samples to estimate a molecular nosology of 20 different disorders (Figure 4).

Discussion. STAR represents an annotation layer built on GEO data, and it provides convenient tools for biomedical experts to derive robust gene signatures from open big data. Here, we implement a validation system that converges on precision of annotations at scale. We do so by rewarding concordance among expert raters. Furthermore, we use machine learning of meta-effects across many thousands of samples with shared phenotypes to estimate a molecular nosology, or functional classification of disease. Our innovative approach uses emerging Internet technologies such as crowd-sourcing and social networks to translate open Big Data in biomedical into structured knowledge that can be used at scale for subsequent large-scale drug and biomarker discovery.

The nosology we estimate very cleanly segregates cancer (PAC=pulmonary adenocarcinoma, HCC= hepatocellular carcinoma, HNSCC=Head and neck squamous cell carcinoma, Lymphoma, Medulloblastoma) from other non-neoplastic disorders. Moreover, this functional representation of disease may suggest clinical utility to repurpose drugs indicated for one disease to another functionally related disease. A good example in our current tree is the proximity of HCC and PAC suggests to consider shared treatments as a potential therapeutic option for either.

Conclusion. Our results prove the translational utility of STAR as an online platform and the feasibility of using crowdsourcing as a paradigm to completely annotate GEO within three years. As we continue to extend our STAR platform, we demonstrate how Internet innovations such as social networks can be used to help characterize disease using open functional genomics Big Data. By estimating a robust and precise molecular nosology of disease, our work allows for massive and systematic drug and biomarker discovery in the near future. Therefore, we are defining the utility of crowdsourcing to translate open biomedical Big Data into useful medical innovation.

Figure 2: STAR annotations. The figure shows the cumulative distribution of 485,054 total annotations over nine months with >90% concordant (green) and <10% discordant (red) annotations that were performed twice, relative to the sample annotations that were only performed once (gray). Blue dashed box labels the effect of $10,000 reimbursement to yield over 360,000 biological annotations in only 6 weeks.

Figure 3: STAR sample annotation. The graph shows the cumulative accumulation of (blue) GEO samples vs coverage with (red) STAR annotations. Linear models (dashed lines) project complete STAR coverage of GEO within three years at current rates.

Figure 4: Tree of disease. The figure shows the clustering dendrogram across 12767 genes across 20 different diseases. For each disease, the number of studies (GSEs), genomic platforms (GPLs), and samples (GSMs) is listed.
Making nursing visible in health information systems

Nicholas R. Hardiker, RN PhD FACMI¹, Nicola Fortune, BSc², Kay Jansen, RN DNP³, Claudia C. Bartz, PhD, RN, FAAN³
¹University of Salford, UK; ²University of Sydney, Australia; ³University of Wisconsin-Milwaukee

Introduction

Nurses are the largest group of health workers in most health care systems. While data-based information can be used to characterize nursing care activities and costs, and to demonstrate the value of nursing, the actual use of information for these purposes has been patchy, making local, national or international comparisons difficult, if not impossible. The World Health Organization’s (WHO) International Classification of Health Interventions (ICHI) is being developed as an international standard for collecting, reporting and analyzing data on health interventions. ICHI spans all sectors of the health system and a wide range of potential applications are envisaged, including use of the classification as a building block for international casemix development. Inclusion of nursing interventions in ICHI is essential to ensure that nursing is represented in the international health information infrastructure of the future. The International Council of Nurses (ICN) is contributing to the development of ICHI, using the International Classification for Nursing Practice (ICNP), a Related Classification within the WHO Family of International Classifications, as a resource for nursing content. The work described in this paper comprises a comparison of content and a gap analysis, using ICNP as a source to identify potential additional content for ICHI.

Methods

There were two phases to the work, centering around two distinct sub-sets of ICNP: a) a set of interventions that were subsumed within the OWL representation of ICNP by the intervention types informing, determining, managing and performing (as more indicative of direct care actions) and b) a much broader set of the remainder of ICNP interventions. In both phases approximate initial candidate mappings between ICNP and ICHI were identified by a member of the ICHI team. Where no mapping could be found, the construction of new interventions by combining relevant ICHI Target and Action categories was suggested (and new categories proposed as necessary). Members of the ICNP team provided advice as to whether ICNP interventions were conceptually equivalent or represented a subclass (more detailed concept) or superclass (broader concept) in relation to the suggested ICHI intervention, using the standard practice of independent review with follow-up consensus work.

Results

In the first phase, potential mappings were identified for 480 ICNP interventions. Reviewers agreed on 324 mappings from ICNP to ICHI (67.5%). Proposals were made to the ICHI development team for the inclusion of new ICHI content, which resulted in sixty-seven new nursing-relevant interventions and seven new Target categories. In the second phase, potential mappings were identified from the remaining 337 ICNP interventions to ICHI. There were 183 additional agreed mappings from ICNP to ICHI (54.3%). This second phase has resulted in further proposals to the ICHI development team, which will inform the inclusion of additional ICHI content.

Discussion

In total there were 817 suggested mappings from ICNP to ICHI, of which 507 were agreed (62.1%). There are a number of reasons behind the lack of mappings for the remaining ICNP interventions, including a) differences in scope between ICHI and ICNP - the focus for ICHI is primarily on direct care activities while ICNP takes a broader view of nursing interventions (a possible explanation for the lower proportion of mappings for the second phase), and b) the absence of ICHI Target categories able to adequately describe some ICNP interventions. This work, a comparison of content and gap analysis, has served as a useful starting point for a larger program of research around nursing and casemix involving an exploration of a) the ability of ICHI to capture existing data-based ICNP-encoded data, in order to concentrate attention on those interventions that nurses actually perform in practice, rather than on a potentially much larger group of interventions that nurses might perform, and b) the potential contribution of ICHI to existing tried-and-tested systems for nursing resource management.

WHO estimates that there are 29 million nurses and midwives across the world; however their contribution remains largely hidden within today’s health information systems. The foundational work described in this paper, and the ongoing research, seeks to help expose the true value (and true cost) of nursing.
A survey of social media for understanding patient-reported medication outcomes

Kimberly Harris, MS\textsuperscript{1}, Boshu Ru, MS\textsuperscript{1}, Lixia Yao, PhD\textsuperscript{1}

\textsuperscript{1}Department of Software and Information Systems, The University of North Carolina at Charlotte, Charlotte NC 28223

**Introduction:** Pre-marketing clinical trials provide limited perspectives about new drugs’ safety and risks, due to marginal patient enrollment and short-term experiments. It is essential to continuously monitor medication outcomes among large and diverse patient populations, in order to thoroughly understand drugs’ long-term effectiveness, side effects, and life impacts [1,2]. Failure to do so may cause serious morbidity or even mortality (e.g., the withdrawal of Vioxx [3]). In response, the United States Food and Drug Administration (FDA) maintains the Adverse Event Reporting System (FAERS) to collect adverse drug events from clinicians, pharmaceutical companies, and patients. However, this system is often criticized for its low reporting rate, undesirable data quality, and potential conflict of interest [4]. In contrast, there is an emerging trend by consumers to discuss their diagnoses and treatments with other people that have similar symptoms and ailments on popular social media platforms, such as PatientsLikeMe and Twitter. In this project, we plan to investigate whether social media can be a complementary data source for medication outcomes research.

**Methods:** We selected four chronic diseases, namely asthma, rheumatoid arthritis, type 2 diabetes, and cystic fibrosis. For each of these diseases, we picked two to three commonly prescribed drugs. Thus, for the total of 11 disease-drug pairs, we investigated three particular questions: (1) do consumers report their medication outcomes and experiences on social media? (2) what social media platform is the best to study consumer-reported medication outcome, according to data volume and quality? (3) what challenges are there to fully analyze the textual data shared by consumers on social media platforms? We selected two professional health social media sites and two general-purpose social media sites as our data sources. The selection of each social media site took into account both its prevalence in the population and data accessibility. The user comments for the 11 disease-drug pairs were downloaded from WebMD, PatientsLikeMe, YouTube, and Twitter. Disease and drug synonyms were used in the search to ensure the completeness of the results. Afterwards, all users’ posts were put into one of four categories: effectiveness, side effect, adherence, and cost at the sentence level, using terminologies, such as Consumer Health Vocabulary. In the end, we did the sentiment analysis using the Stanford sentiment analysis tool [5].

**Results:** Table 1 summarizes the number of user posts from WebMD, PatientsLikeMe, YouTube, and Twitter for each disease-drug pair. The results demonstrate that consumers did post a lot of information on social media relevant to medication outcomes for all four diseases. Though there were fair amounts of relevant text content posted on each social media platform, WebMD contained the richest information regarding medication outcomes among the four. Both WebMD and PatientsLikeMe provided rating schemas to reflect users’ opinions of medication outcomes in a quantitative manner. The Pearson’s correlation coefficient equaled to 0.728 and demonstrated consistency in user reports of drug effectiveness for these two sites. On PatientsLikeMe, however, only 3% of the users described their medication experiences in free text. Majority of the posts on YouTube and Twitter contained irrelevant content, such as drug related news, commercial advertisement, and clinical study or publication announcements, with few relating to medication outcomes and experiences. Figure 1 illustrates the sentiment analysis results associated with the users’ comments on different medication outcome topics. Negative comments and side effects dominated on all four social media platforms.

**Discussion:** While reviewing the comments retrieved, we found a few users discussed how the drugs they were taking unexpectedly helped their secondary conditions, which exemplified potential opportunities for drug repositioning [6]. Users on WebMD and PatientsLikeMe appear to be more conscious and knowledgeable about their drug therapies. Their feedback is usually more informative than those on YouTube or Twitter, which often lack context. Also, majority of the posts consists of adult-results, and not those reflective of teenagers or children. It will be interesting to see how and where the younger generation posts their observations in future studies. Furthermore, consumers wrote with language that is challenging for computers to process, such as sarcasm, grammatical errors, typographical facial expressions, comparative opinions about different drugs, and various phrases for analogous attitudes. Despite those challenges, we believe social media can be a complementary new data source because of its high prevalence in the population and its independence from other data sources, which enables us to use it to validate the patterns identified in the traditional data sources. Our future works will focus on implementing natural language processing and text mining methods suitable for using social media to systematically mine medication outcome contents on a large scale.

Impact of Electronic Health Records on Quality of Care: Evidence on Inpatient Mortality, Readmissions, and Complications

Tina Hernandez-Boussard, Doug Morrison, Swati Yanamadala, Catherine Curtin, Kathryn McDonald

Research Objective: It has been suggested that health information technology, particularly electronic health records (EHR), will improve quality and efficiency of healthcare organizations and many hospitals have implemented these systems. However, little evidence exists on the association between EHR adoption and improved quality of care across a broad range of medical and surgical conditions. We hypothesized that hospitals with fully-implemented EHR-systems [Full-EHR] would have lower levels of inpatient mortality, 30-day all cause readmissions, and complications (measured by Patient Safety Indicators [PSIs]), compared to hospitals with no or partially implemented EHR-systems [No-EHR and Partial-EHR, respectively].

Study Design: We used data from the Healthcare Cost and Utilization Project (HCUP) and the American Hospital Association annual surveys (AHA) from California, Florida, and New York, 2008-2011. Cross-sectional random-effect logistic regression models were used to determine associations between EHR implementation level and quality of care. Relative-risk difference in differences analyses (DiD) were used to determine the effect of implementing an EHR-system on quality of care.

Population Studied: We included surgical patients undergoing coronary artery bypass graft, pulmonary lobectomy, open abdominal aortic aneurysm repair, endovascular abdominal aortic aneurysm repair, or colectomy (n=202,936) and medical patients receiving care for acute myocardial infarction, coronary heart failure, and pneumonia (n=439,410).

Principal Findings: Medical and surgical patients sought care at hospitals reporting No-EHR (10.1%), Partial-EHR (56.5%) and Full-EHR (33.4%). Patients at hospitals with a Full-EHR had the lowest rates of inpatient mortality, readmissions, and PSIs followed by patients at hospitals with a Partial-EHR and then patients at hospitals with No-EHR. (p<.05); surgical patients demonstrated between a 9-15% decrease and medical patients had between a 5-12% decrease in rates. Adjusting for patient and hospital characteristics, both medical and surgical patients at hospitals with Full-EHR had between 7-24% lower relative risk for inpatient mortality, readmission, and PSIs compared to patients at hospitals with No-EHR and Partial-EHR. However, the DiD found EHR implementation had a minimal effect both in medical and surgical patients on inpatient mortality readmission, and complications.

Conclusions: Patients seeking care at hospitals with either a fully implemented or partially implemented EHR-system had lower rates of inpatient mortality, readmission, and PSIs compared to patients at hospitals with No-EHR. These benefits were significant for both surgical and medical patients and varied by
specific medical condition and procedure. However, the DiD analysis suggests that factors other than EHR implementation account these differences in quality.

**Implications for Policy and Practice:** As federal incentives encourage EHR adoption and hospitals strive for meaningful use, it will be important to understand the benefits received from EHRs. Under the healthcare reform, all parties focus on the quality of care received and EHRs might play a smaller role than expected. Our results suggest that EHR-associated improved quality, safety, and efficacy might vary by type of care and meaningful use targets should reflect such variations.
Discharge Instructions: What Do Patients Remember?
Brent Hill, RN MS PhD, Qing Zeng-Treitler, PhD
University of Utah, 421 Wakara Way, Ste 140, Salt Lake City, Utah 84108

Introduction When a patient leaves the hospital, he is provided with instructions for his post-hospitalization care, follow-up appointments and tests, and other patient education information. However, patients have a difficult time understanding their discharge instructions.[1-3] The objective of this study is to understand the types of information patients remember and do not remember in their discharge instructions. This information will be used to inform informatics interventions to improve patient comprehension, recall and adherence to discharge instructions. This study builds on prior research in which illustrated versus non-illustrated discharge instructions were tested with 144 patients to evaluate their recall of and satisfaction with their discharge instructions.[4, 5] The first 50 discharge instructions were analyzed for this pilot study.

Methods Patients on a Cardiovascular Medical Unit at the University of Utah Hospital were asked to remember the content of their disease or procedure specific discharge instructions after their final discharge teaching was completed by their nurse and they were discharged to go home. Study participants were asked to review their instructions for up to 15 minutes then prompted by the study nurse to recall their instructions as the nurse asked them to state all of the information they could remember as the nurse read the title of each discharge instruction section such as diagnosis, signs/symptoms to be vigilant for, wound care, activity restrictions until each section was reviewed. Finally, the patient was asked for any additional information they recalled. Three levels of analysis were conducted for this study. The first level of analysis consisted of reviewing discharge instructions by section. The second level of analysis consisted of reviewing discharge instructions in detail by individual instruction. The third level of analysis evaluated the information based on the immediacy of the need for the instruction. Patient’s discharge instructions were based on their diagnosis or procedure so instructions varied. Content analysis was completed by quantification of instructions by remembered or did not remember and a ratio was calculated based on the percentage of participants who received that instruction who did or did not remember the instruction.

Results The results for the first level of analysis revealed the percentages patients did/did not remember in the following sections of discharge instructions: Diagnosis (78/22), General Care (17/83), Wound Care (26/74), Activity Level (22/78), Restrictions (39/61), Diet (24/76), Other (4/96) (Table 1). The second level of analysis presents selected discharge instructions and the percent of patients that did and did not remember the instruction (Table 2). The third level of analysis examined the immediacy of instructions versus general health education. A cardiologist independently evaluated the discharge instructions for immediacy of information by highlighting information that he deemed necessary for the patient’s first week post-hospitalization. Analysis of the instructions revealed that 27% of the discharge instructions were necessary for 1 week post-hospitalization and 73% of the discharge instructions consisted of general health education.

Discussion It is necessary to understand how patients retain information from discharge instructions in order to prioritize the content and delivery of discharge instructions. Suggested improvements include: simplify text, stratify information based on need, and use different delivery methods such as traditional paper, electronic via email or PHR, and utilize info graphics or pictographs. This information will be used to inform informatics interventions that will tailor and deliver information for the patient that can support the patient during this transition of care.

What Are Frequent Data Requests from Researchers? A Conceptual Model of Researcher’s EHR Data Needs for Comparative Effectiveness Research

Gregory W. Hruby¹, MA, Praveen Chandar¹, PhD, Julia Hoxha¹, PhD, Eneida A. Mendonça²,³, MD, PhD, David A Hanauer⁴,⁵, MD, MS, Chunhua Weng, PhD¹
¹Dept. of Biomedical Informatics, Columbia University, New York, NY; ²Dept. of Pediatrics; ³Dept. of Biostatistics and Medical Informatics University of Wisconsin, Madison, WI; ⁴Dept. of Pediatrics, ⁵School of Information, University of Michigan, Ann Arbor, MI

Introduction

Data request forms are the key communication media linking medical researchers and informaticians¹. A recently published Carpenter framework organizes data needs for cancer comparative effectiveness research². It complements the PICO framework that defines the Patient, Intervention, Comparison, and Outcome constructs for specifying clinical information needs³-⁵. Our goals are to validate, enrich and generalize the Carpenter framework utilizing three data sources representing researcher information or data needs. We posit the Carpenter model may serve a standard template for data needs specification as it contains semantic structural similarities to the PICO framework. We redefined the model as a representation of abstract medical concepts used in research. We extended the Carpenter framework by expanding the model’s breadth to multiple medical research domains.

Methods

We utilized three data sources for this study: Clinical trial inclusion/exclusion criteria, EHR SQL project queries, and EHR data request logs. Each source represents a unique aspect of data needs specification across different research needs and different medical disease domains. For example, clinical trial inclusion/exclusion criteria provide ideal data needs specification for the definition of cohort identification across a diverse set of diseases while the EHR SQL project queries provide a comprehensive list of explicit granular concepts organized within the context of real world data needs used for retrospective CER of benign and malignant urologic diseases.

We parsed each dataset to the sentence/variable level. From the clinical trial inclusion/exclusion criteria and the EHR data request logs, we randomly selected 1,000 and 897 sentences, respectively. From the SQL project files, we extracted 1,445 distinct variables. Each dataset was iteratively annotated with the Carpenter framework by one coder (GH). Nodes were removed or added to the Carpenter framework when the concept was not used, or the concept did not previously exist, respectively. The proposed model was created with the enriched concept list. Domain experts evaluated if the functionality of the enriched model meets the intended purpose: a guideline to aid the specification/elicitation of EHR data needs used in research.

Results

Figure 1 represents the enriched framework. Six original child nodes were pruned from the Carpenter framework. Pruned nodes, e.g. Local disease burden, health norms, care process guidelines, and care systems and coordination, are not well represented in the EHR and as such, many medical researchers would forgo any mentioning of these concepts. Fifteen additional leaf nodes were added to the representation and are shown by an underlining of the concept within the figure. The Organizational/Provider Characteristics parent node (the boxes) was moved to the second column in the proposed model, as the data suggested it was more related to the parent nodes, Detection/Diagnostics and Intervention, rather than the Patient node. For the attribute of completeness, the model correctly identified 88% (63/72) of the medical concepts generated by our expert evaluators. For the attribute of generalizability, the model accurately identified medical concepts from diverse medical domains with a median accuracy rate of 91% (60-100%). For the attribute of reusability, the enriched model reused 68% (53/78) of the concepts from the original Carpenter model.

Discussion

This study contributes an enriched conceptual model representing the medical concepts used in clinical research. The major contribution of the enriched model is not the granular nodes, but it’s representation of the researcher’s conceptual organization of medical concepts used for research. This may serve as a bridge between the medical researcher and the informatician by aligning the informatician’s mental model to researcher’s. Both stakeholders may use this model to specify and elicit key medical concepts needed for the research project.
Figure 1. The enriched model. The blue directed edges represent a temporal process as the patient moves through the care continuum. The cyclical nature of this graph implies the patient can re-enter the care cycle. The undirected edges indicate an association between the modules. The boxes represent parent nodes and the concepts within the boxes are the child nodes related to the parent nodes.

Introduction: Patient portals can improve patient engagement and health among patients with chronic diseases, but uptake and use of portals differs across racial/ethnic and socioeconomic groups. This study aims to examine the association between level of internet access, a possible underlying cause of the observed differences, and patient portal use among patients with chronic conditions in a large integrated health system.

Methods: In an integrated health delivery system with a web-based patient portal since 2005, patients can access personal medical information and interactive tools to manage health care at no charge, including viewing lab results and visit summaries, secure email messaging with health care providers, medication refill orders, and wellness programs. We studied use of the portal in 2013 by adult patients (aged 18 or older) in the chronic disease registry for risk of cardiovascular events (including diabetes, coronary artery disease, stroke, abdominal aortic aneurysm, and peripheral vascular disease) who were also continuously enrolled in the health system in the previous year. Level of internet access was measured by federal data for percent of households with a residential fixed high-speed internet connection in the census tract of the patient’s residence, categorized as low (<60% of households have internet connection), medium (60-80%) and high (>80%). We used logistic regression models to examine the association between level of internet access and portal use in 2013 (any portal use, lab result review, and secure messaging), adjusting for age, gender, neighborhood socioeconomic status, race/ethnicity, number of comorbid conditions in 2012 (as a measure of clinical need), history of medication adherence (as a measure of patient engagement), and medical center, and then used model results to calculate adjusted rates.

Results: Among 273,815 patients, 56.9% were 65 or older, 45.8% had non-white race/ethnicity, 21.0% lived in a low socio-economic-status neighborhood, and 49.2% were not adherent to previously prescribed chronic medications (proportion of days covered by medication <80%). Overall, 10.5% of all patients lived in a neighborhood with low internet access, 40.8% with medium, and 48.7% with high levels of internet access. Among all patients, 64.7% had used the patient portal for any tool (56.3% used the tool for lab results review and 58.6% used the tool for secure messaging) in 2013. Descriptively, use of the portal varied among patients with different level of internet access (low: 52.0%; medium: 61.4%; high: 70.2%). After adjusting for patient socio-demographic and clinical characteristics (Table), patients with higher level of internet access were more likely to use the portal overall (among low access: 58.1% used the portal, 95%CI: 57.4%-58.8%; among medium access: 62.1%, 95% CI: 61.8%-62.5%; among high access: 68.4%, 95%CI: 68.0%-68.7%). Those with higher internet access were also likely to use the tool for lab results review (low: 49.6%, 95% CI: 48.9%-50.3%; medium: 53.5%, 95% CI:53.2%-53.9%; high: 60.0%, 95% CI: 59.6%-60.4%) and more likely to use the tool for secure messaging (low: 51.7%, 95% CI: 50.9%-52.4%; medium: 56.1%, 95% CI: 55.7%-56.5%; high: 62.3%, 95% CI:61.9%-62.7%) . These patterns were consistent in analyses restricted to patients who had registered to use the portal.

Discussion: Patients with higher levels of neighborhood-level internet access were more likely to use patient portals, including specific lab result review and secure messaging tools, even after adjusting for patient socio-demographic characteristics, clinical need and patient engagement. The findings suggest that lack of home internet access may be a barrier to patient portal use. Future research should compare neighborhood-level measures with individually-reported access measures, including through mobile devices.

Usability Testing of an Ambulatory Navigator

Introduction

Although EHRs are widely used in clinical practice, poor user interface (UI) design continues to be a significant barrier to effective use of these systems for clinical care. These design problems can be tied to poor system usability. One approach to make EHRs more usable is to follow user-centered design (UCD) practices, which often includes formal usability testing. In response to clinician problems and challenges with a navigator in a new EHR, individuals at a large health system redesigned an ambulatory navigator within the EHR. Usability evaluations of two versions of an ambulatory navigator were conducted to understand if the new navigator improved user performance and satisfaction.

Methods

The original navigator (Figure 1) consisted of a column of links divided into domains. The redesigned navigator (Figure 2) was created in an iterative process in which clinicians from different specialties were directly involved in providing design guidance and testing of the navigator and had opportunity to provide guidance and feedback. In the final design of the new navigator, there are two buttons called “Intake” and “Charting”, and clicking either of these tabs show options pertaining to nursing/clinic staff and provider roles. The evaluation of the navigators utilized an EHR training environment replicating the production EHR with synthetic standard patients. Five patients of similar complexity were selected. Users completed a set of tasks for each patient, designed to align with Meaningful Use Stage 2 requirements. Tasks were first pilot tested with two residents and found to be similar in complexity, taking a similar amount of time to complete and being subjectively reported as similar difficulty. A convenience sample of residents (n=8) was recruited for this study. Participants completed three patient cases in each navigator and were randomly assigned to start with the original or redesigned navigator. Participants were asked to think aloud while performing tasks, and completed a set of surveys after each case and at the end.

Results

Participants were experienced EHR users but were not experienced using either of the two versions of the ambulatory navigator. Time to complete tasks varied widely across participants. Within participants, each of the six patient cases took similar amounts of time, indicating that the cases were of similar complexity. Average time to completion for five of the six patient cases was longer in the new navigator. Scores on the systems usability survey suggested that participants had mixed preferences between the two navigators, with a slight overall preference for the new navigator. Data from the think aloud procedure revealed that all participants encountered usability problems while completing tasks in both navigators and expressed differing preferences between the two navigators.

Discussion

Despite the time and effort given to redesigning the navigator, provider preferences were mixed, and time to complete tasks was longer with the new navigator. This indicates that designing EHR interfaces is a very complex and difficult process, even for a single section of an EHR interface. This study is limited by its small sample size of residents from one specialty at one institution, and participants had varying levels of skill using EHRs. Efforts to redesign EHR interfaces are complicated by differences in user preferences and experiences and tension exists between the benefit of standardization and allowing for customization based on preferences. Future work should further explore how the design process can account for differing preferences in EHR interface design and to measure how changes in EHR interface design impact perceived workload and time to complete tasks.

Process Mining of Growing Adoption of Genomic Precision Medicine Testing Using Commercial Claims and Encounters Database

Vojtech Huser, MD, PhD

1Lister Hill National Center for Biomedical Communications, National Library of Medicine, National Institutes of Health, Bethesda, MD

Introduction

Many studies show increasing penetration of genomic testing to support precision medicine. In 2012, the American Medical Association created new codes to facilitate billing of molecular pathology (MoPath) tests using Current Procedural Terminology [CPT] codes 81200 – 81479 and G0452). Many genetic labs admit that such enumeration of genomic tests is incomplete1 and that they often have to resort to generic codes (eg, CPT:81479 “Unlisted molecular pathology procedure”). Despite these limitations, examination of a large administrative dataset can offer unique national level insight into the gradual adoption of precision medicine molecular testing; we present such an analysis. In addition, we reviewed test catalogs of several laboratories to compare genomic tests linked to the same CPT code with a special focus on how exome sequencing is presented and billed by different labs.

Methods

We used MarketScan Commercial Claims and Encounters (CCAE) dataset that contains data from privately insured population and contains patient-level de-identified claims data from inpatient and outpatient visits and pharmacy claims of multiple insurance plans. Access to this dataset was provided by the Innovation in Medical Evidence Development and Surveillance (IMEDS) project of the Reagan-Udall Foundation (RUF) for the Food and Drug Administration. CCAE is one of the largest current healthcare datasets with data on 141.8 million patients (Mean age: 36 (SD:18.57); Time-span: 2003-2013; Drug records: 2.8 billion NDC pharmacy dispensing claims + HCPCS/CPT/ICD9Proc drug codes (inpatient/outpatient claims); Dx:4.6 billion ICD9 codes (inpatient/outpatient claims); Procedures: 10 billion HCPCS/CPT/ICD9Proc codes (inpatient/outpatient claims); Laboratory data and observations: 385 million LOINC-coded outpatient results). We used process mining techniques, Structured Query Language (SQL), R language and tools developed by the Observational Health Data Sciences and Informatics (OHDSI) community.

Results and Discussion

To facilitate comparison and execution on other datasets, we used the R Markdown format designed for reproducible science that combines the analysis code with the resulting analytical report (see project repository for code [*.Rmd] and output reports [*.docx]). Because the CCAE dataset is formatted in the OHDSI Common Data Model (CDM v4; mainly tables PROCEDURE_OCCURENCE, PROCEDURE_COST and PERSON), our analysis can be repeated on refreshed data or on comparable datasets (in CDM format) from other institutions. We extracted 324,334 molecular pathology testing events for a total of 143,811 patients. 62,358 patients (43%) had more than one genomic test. We classified all molecular test claim codes into three categories: (1) gene-specific codes, such as “KRAS gene analysis, codons 12 and 13”; (2) pharmacogenetics codes, such as “CYP2C19 gene analysis, common variants”, and (3) generic codes (CPT Tier 2), such as “Molecular pathology procedure, Level 8 (eg, 26-50 exons)”. Table 1 presents an overview of selected set of parameters for a demonstrative subset of codes. For each test we looked at usage over time (sample shown in Figure 1 for a MLH1 gene test used in Lynch syndrome), associated diagnoses (using CDM’s ‘relevant_condition_concept_id’ column) and average costs (paid by the health plan and the patient) and cost variability. See project repository for a complete list and all generated graphs. This analysis is part of our larger effort to characterize EHR data of genomic precision medicine patients. From an informatics standpoint, our analysis also represents a case study where a distributed cloud database (RedShift engine running on an Amazon cluster of eight dw1.xlarge servers; total of 16 vCPUs, 120GB memory and 16TB storage) provided highly performing analytical environment. The genomic tests extraction that involves a join of two largest tables in the largest IMEDS dataset (10 billion rows with joined cost data) executed in 5.2 minutes.

Claims data show increasing adoption of genomic testing over time. Review of laboratory catalogs reveals significant differences that are also reflected by highly variable cost data. Recent FDA regulatory actions that may limit laboratory-developed tests may lead to further standardization of claims data. Standardization of genomic events using non-CPT based approaches in non-claims-only EHR data can enable much more detailed analyses.

A Road Map for a National Health Information Technology Safety Center

Douglas Johnston, MTS¹, Andrew Gettinger, MD², Kathy Kenyon, JD³, Stephanie Rizk, MS⁴, Colene Byrne, PhD⁵, Linda Dimitropoulos, PhD⁶
¹, ⁴-⁶RTI International, Raleigh-Durham, NC; ²,³Office of the National Coordinator for Health Information Technology, Washington, DC

Abstract
Prior work by federal advisory committees and agencies identified the potential value of a national health IT safety center. We describe the process for developing a road map for such a center – including its vision, objectives, core functions and operating model. Whether or not a center is funded, this road map identifies potential high value functions and activities requiring multi-stakeholder engagement in order to maximize the potential for health IT to make care safer.

Introduction
Recent studies present accumulating evidence that adoption of health IT has made progress toward important quality and safety goals.¹ At the same time, some studies have found that health IT is a contributing factor to adverse events and near misses.²,³ A number of reports have further described health IT safety risks and the actions needed to address them.⁴⁻⁵ Recently, the draft FDASIA report proposed creating a national health IT safety center as a trusted convener of health IT stakeholders in support of these efforts.⁶ In September 2014, the Office of the National Coordinator for Health Information Technology (ONC) contracted with RTI International to convene a multi-stakeholder task force to provide input into a road map for a potential health IT safety center. The methods and inputs used to develop the road map, and its results, are described below.

Methods
To develop this road map, a task force of nationally-recognized experts and stakeholders was convened to provide input on the center’s vision, core functions, and operating model. The task force represented the likely participants and audiences for a national health IT safety center. To guide road map development, the task force was provided a list of operational considerations as well as a summary of federal agency authorities that would limit a center’s abilities to conduct certain activities (Table 1). The task force both defined the general functions of the center, as well as priority areas – such as the development of actionable solutions for high risk safety issues – to ensure value for stakeholders participating in the center. Central to all functions was engaging private-sector stakeholders in ways that support and advance (and do not supplant) their health IT safety initiatives and responsibilities.

The health IT safety center as envisioned would potentially work with individuals and organizations in the private sector and government to create a learning system committed to 1) using health IT to make care safer and 2) to continuously improving the safety of health IT. To meet these fundamental objectives, its activities will lead to improvements in: identification of health IT safety events and hazards; evidence, awareness, and knowledge around health IT safety; health IT safety tools, best practices, interventions, and education; safe use of health IT through improvements in design, usability, competence, and other areas; and uses of health IT to improve patient safety. The center is envisioned as a public-private entity, potentially governed by a multi-stakeholder body of representatives from research and academic institutions, health IT vendors, patient safety organizations, insurers, provider organizations, patient advocates, federal agencies, and others.

Results and Discussion
The health IT safety center road map will be completed in late spring of 2015. In addition to the overview provided above, our proposed presentation in the November 2015 AMIA Annual Symposium will review the core elements of the road map. Our talk will provide AMIA audience members with an opportunity to learn and ask questions about the road map, and to discuss a potential health IT safety center as well as other mechanisms to foster multi-stakeholder collaboration to address the core high value functions and activities identified in the road map.

Introduction

Genome-wide Association Studies (GWAS) provide hypothesis-free investigation of the whole genome. However, GWAS have limited ability to identify clinically significant variants, and account only for a portion of the predicted phenotypic heritability. In addition, most GWAS-significant single nucleotide polymorphisms (SNPs) are located in intergenic regions, which make the interpretation of biological mechanisms more challenging. As a complement to GWAS, Phenome-wide association studies (PheWAS) offer insights into the biological mechanisms that predict disease susceptibility, and help to determine promising polymorphisms or variants for further study.1

Methods

As part of the eMERGE network,2 we developed and validated a rule-based algorithm to find cases and controls for diverticulosis and diverticulitis in adult eMERGE subjects using electronic health record (EHR) data. At all but two sites, we selected subjects from patients having colonoscopies or abdominal imaging: Natural Language Processing (NLP) was performed on the reports from those procedures, and any subject that had any asserted mention of “diverticul*” in those reports was recorded as cases, plus any with an asserted mention of diverticulitis were noted. Conversely, controls had at least one colonoscopy and no asserted mentions of “diverticul*” in those reports. For two sites where NLP of all reports was not possible, cases were selected as above, plus only those diagnosed (using ICD-9 codes) with diverticulosis or diverticulitis within 7 days after the procedures were selected as cases. Conversely, controls were also the same, but in addition had to have no diagnosis ever for diverticulosis or diverticulitis. Three sites validated3 algorithm performance by chart review of a combined total of 300 randomly selected charts of cases and controls to ensure a high positive predictive value (PPV). We performed GWAS of diverticulosis cases, versus the subset of those with diverticulitis, and versus controls, stratified by race. We selected the top SNPs associated with diverticulosis versus controls, and versus diverticulitis for the PheWAS. We used logistic regression adjusted for age and sex assuming an additive genetic model, on the eMERGE adult cohort of ~38,000 individuals, and also on various subsets, including just those with diverticulosis, and diverticulitis, using the R PheWAS package.4

Results

Validation of the phenotype algorithm resulted in 98-100% PPV at 2 sites for cases and controls, and 88% PPV at a third site for cases, which has subsequently updated their NLP system to correct the errors found. We identified 6297 diverticulosis cases, of which 734 had diverticulitis, and 5090 controls. The GWAS found 39 SNPs to be highly associated (p<10^{-6}) with either diverticulosis and/or diverticulitis and we selected the top SNPs (rs76633992, rs62382461) with the lowest p-values (p=9.28E-08 and p=4.62E-08) that were also near known genes from each population of European and African Americans, respectively, for further investigation by PheWAS. The PheWAS identified several significant associations with cardiac disorders, including abnormal electrocardiogram and cardiac arrhythmia (Figures 1, 2), and with several types of skin disorders (Figure 2).

Discussion and Conclusion

Our findings reinforce the utility of PheWAS as a tool for not only replicating genotype-phenotype associations but also providing insight into potential promising pathways for further investigation. In particular, one of our results replicates the previous GWAS finding of an association between the CAV2 gene and cardiac arrhythmia.5 In addition, as a disease of epithelial cells, the association of these SNPs associated with both diverticulosis and skin disorders is biologically plausible and may suggest a possible disease pathway. Ongoing work is underway to validate the GWAS results for all adult eMERGE diverticulosis case and control subjects, and performing additional PheWAS analyses.
Figure 1. PheWAS plot showing correlation of SNP rs76633992 (correlated with diverticulosis via GWAS) with cardiac arrhythmia in European American cohort.

Figure 2. PheWAS plot showing correlation of SNP rs62382461 (correlated with diverticulosis/diverticulitis via GWAS) with abnormal ECG(electrocardiogram) and various types of skin disorders in African American cohort.

Natural Language Processing facilitates delivery of individualized recommendations at the point of care

Mayo Clinic, Rochester, MN, USA

Introduction

Mayo Clinic has made significant strides in developing knowledge assets and the tools to manage them. To fully realize the value of these assets, it is pertinent not only to embed the knowledge into the clinical workflow but also contextualize the knowledge to individual patients. To ensure the delivery of standard guidelines, we have created care process models (CPMs) for various conditions. However, individualized patient care according to CPMs requires the review and obtainment of relevant clinical information from both structured data fields and unstructured sources of information such as clinical notes, lab reports, etc. While information in structured fields is highly useful, the integrated information from both structured and unstructured repositories at various time points provides comprehensive views during personalized decision-making. Here, we discuss a multi-stage iterative development of an NLP system that extracts data elements needed for automating care process models for hyperlipidemia, atrial fibrillation and heart failure. We also investigated how NLP helps to fill the information gap that exists in structured data sources and empowers clinical decision-making at the point of care.

Methods

As the first step, we developed a gold standard corpus, which was identified through stratified sampling from a retrospective cohort for the data elements pertaining to the three care process models (CPMs) namely Atrial Fibrillation, Heart Failure and Hyperlipidemia. Two nurse abstractors carried out the annotations based on the guidelines (Supplementary File1) outlined by domain experts. The nurse abstractors annotated 165 clinical notes in three batches (55 clinical notes per batch). Based on the gold-standard annotations from clinical notes and standard ontological sources such as ICD9-CM, SNOMED-CT, we developed regular expressions using MedTagger to extract (See Supplementary File2) the data elements from selected sections in clinical notes. The choice of a rule-based approach stems from the overall goal of the project to achieve a very high precision (~100%), at the cost of lower recall. We used an iterative approach (Figure 1) to develop the rule-based NLP system. At the end of the first batch annotation, we used the gold standard annotations to design regular expressions to extract the data elements from clinical notes. We iteratively refined the rules developed to extract data elements based on the analysis carried out after each run.

Results

The system was evaluated against the gold standard annotated data set in an iterative manner. Table1 lists the performance of the NLP system in terms of precision, recall and F-measure (standard metrics for evaluation) against batch2 and batch3 data sets. In the first iteration, the system developed based on batch1 gold standard was evaluated against batch2 data set (Row 2 in Table1). In the second iteration, we refined the rules to fix errors observed in iteration 1 and evaluated the resultant system against the batch3 data set. After a couple of iterations, the system achieved desirable levels of performance. The above evaluation reflects the ability to extract data elements by the NLP algorithm on a smaller data set. We also conducted a pilot evaluation regarding the impact of NLP on individualized care recommendations made on 14,000 patients. Based on the data outlined in Table 2 & Supplementary File3 we infer that when the NLP system decisions when combined with the information in structured data made significant differences to the care recommendations to 1,730 patients. From Table 3, Supplementary File3 and 4 we can infer that the NLP system while reversing the care recommendations for 155 patients, has suggested alternative care recommendations to 1, 885 patients. We will soon realize the robustness of the NLP recommendations as the physicians are reviewing the care recommendations made by MEA in the pilot study.

Conclusions and Future work

We have successfully integrated an NLP system into an EMR agnostic care recommendation solution system, MayoExpertAdvisor. The adopted batch-wise iterative system development has yielded a robust NLP system with acceptable performance.

Population Level Clinical Analytics Using the MapReduce Framework and a Production Rule System
Neelima Karipineni, MD, MMSc1,2,3, Howard S. Goldberg, MD1,2,3
1Partners HealthCare System, Wellesley, MA; 2Division of General Internal Medicine and Primary Care, Brigham and Women’s Hospital, Boston, MA; 3Harvard Medical School, Boston, MA

Introduction

We have demonstrated use of a highly scalable web-service-based decision support service, the Enterprise Clinical Rules Service (ECRS), in several patient-centered clinical decision support applications1-3. We repurposed this system to author population level rules that calculate a risk score for thromboembolic events in patients with non-valvular atrial fibrillation, the CHA2DS2-VASc score4, and determine whether the patient is appropriately anticoagulated. We found utilizing our production web service in batch mode, as we do to retrieve real-time clinical decision support recommendations, to be inefficient for large volume data. Hadoop is an open-source Apache Foundation project which at its core includes an implementation of a parallel computing framework, MapReduce, and a distributed file system, the Hadoop Distributed File System (HDFS). This framework has a number of potential benefits over our current process, including decreased network usage and ease of scaling clusters.

Methods

The ECRS architecture integrates a commercial production rule system, Operational Decision Manager (IBM, Armonk, NY) with internally developed terminology and classifications services. The system allows clinical analysts to write decision support rules in an English-like language against a shared patient information model (PIM), which is populated from input data in standard formats, such as the Continuity of Care Document (CCD). We extracted the rule application as a Java package and used a distribution of the ODM execution engine to execute the rules in the Map portion of a MapReduce process. We tested combinations of custom Map and Reduce implementations, as well as input file formats, on a set of 5,060 PIM XML files. We compared CPU, memory, and disk usage for each, averaging results over three runs. All tests were performed on a single virtual machine running CentOS 6.6 and Hadoop 2.6.0 in pseudo-distributed mode, with 8GB of memory and four Intel(R) Xeon(R) CPU E5-2690 v2 3.00GHz processors, giving us the ability to run three concurrent Mappers per job.

Results

As shown in table 1, all five tested configurations gave us significant performance improvement over sequential calls to a web service, which took approximately 117 minutes with the same data set. As expected, the configuration without a Reduce phase gave us the best performance and least resource utilization. Of the configurations including a Reducer, using the core SequenceFileInputFormat was the most efficient, primarily due to decreased disk reads from HDFS. However, sequence file creation from individual XML files added an additional 1.64 minutes in overhead, negating much of the time performance benefit. The first and second comparisons gave similar performance, with a small, not statistically significant advantage in the configuration deserializing the Patient object from XML in the Mapper rather than in the record reader.

Discussion

While our distributed process reduced runtime by as much as 97%, we found a fundamental mismatch between our use case and the MapReduce framework: the framework is optimized for simple logical operations performed on a very large amount of unstructured or semi-structured data provided in a few large files. We, however, tested an implementation of fairly complex logic on a small amount of well-structured data provided in many small files. The process of extracting data from clinical systems, transforming it into interoperable models, and running classification and translation terminology services far outweighed the time taken to execute the rules by any compared method. Using a MapReduce framework would be best suited to persistent, pre-existing patient data sets. On an average day, the Partners HealthCare clinical document repository stores upwards of 12,000 CCDs for outpatient clinic visits alone. In the future, we would explore techniques for de-identification and institutional barriers to use of existing patient data repositories such as this for large scale analyses. We would further explore scalability in terms of data set size and cluster size.
 Configuration (InputFormat Mapper <K,V> Reducer <K,V>) | Elapsed time (min) | Total CPU vcore-seconds | Total memory megabyte-seconds | Total local data (bytes) read written |

Demonstrating the Advantages of Applying Data Mining Techniques on Time-Dependent Electronic Medical Records

Uri Kartoun, PhD1,2, Vishesh Kumar, MD1,2, Su-Chun Cheng, ScD3, Sheng Yu, PhD3, Katherine Liao, MD, MPH2,4, Elizabeth Karlson, MD2,4, Ashwin Ananthakrishnan, MBBS, MPH2,5, Zongqi Xia, MD, PhD2,5, Vivian Gainer, MS6, Andrew Cagan, BSc6, Guergana Savova, PhD2,7, Pei Chen, MS2,7, Shawn Murphy, MD, PhD6, Susanne Churchill, PhD5, Isaac Kohane, MD, PhD2,5, Peter Szolovits, PhD5, Tianxi Cai, ScD3, Stanley Y. Shaw, MD, PhD1,2

Division of Rheumatology, Brigham and Women’s Hospital (BWH), Boston, MA; 5. i2b2 National Center for Biomedical Computing, BWH, Boston, MA; 6. Research Computing, MGH, Boston, MA; 7. Clinical Natural Language Processing Program, Boston Children’s Hospital, Boston, MA; 8. Computer Science and Artificial Intelligence Laboratory, Massachusetts Institute of Technology, Cambridge, MA.

**Summary:** We demonstrate several advantages of applying data mining techniques on time-dependent Electronic Medical Records (EMR), specifically: 1) combining structured and unstructured variables improves the accuracy of a type-2 diabetes (T2D) classification algorithm, 2) conducting a quantitative survey of multiple comorbidities is important in T2D especially cardiovascular complications with hazard ratios, 3) analyzing time dependent variables can clarify time dependent contributions to variety of comorbidities, and specifically of the “obesity paradox”, and 4) demonstrating that an unbiased examination of physician treatment patterns reveals changes over time consistent with clinical trials.

**Background:** Cohorts assembled from EMR present a potentially powerful resource to study T2D and cardiovascular complications at population scale. Recent reports have demonstrated the utility of EMR analysis to discover genotype-phenotype correlations, sub-categories of disease, and adverse drug events.

**Methods:** We developed a classification algorithm to identify T2D patients based on characteristics including clinical notes, diagnosis and procedure codes, medications, and laboratory tests. We analyzed an EMR database at MGH and BWH considering patients who received care between 1990 - 2013. We applied logistic regression with the adaptive LASSO using different combinations of variables such as structured variables only, unstructured variables only, and combination of all variables. To determine the level of association between clinical and demographic variables with mortality we developed baseline and lagged-time varying Cox regression models that included an adjustment to ethnicity and time varying covariates. To assess how therapeutic choices change over time, we calculated sparse covariance matrices for heart failure related concepts extracted from clinical notes.

**Results:** Our classification algorithm identified 65,099 T2D patients with a specificity of 97% and PPV of 96% based on “gold standard” physician chart review. 56,691 patients (87.1%) had two and 38,449 patients (59.1%) had four or more chronic conditions, demonstrating the complexity of the cohort. Cox regression models indicated statistically significant HRs > 1 for CHF, CAD, and CVD, and HRs < 1 for PCI and CABG. Increasing BMI was associated with lower mortality as compared to the reference BMI (< 25 kg/m²). Further stratifying the results into 1, 3 and 5 years analysis, this “obesity paradox” is strikingly obvious at short-term follow-up of 1 year, suggesting that patients with low BMI were suffering from chronic medical conditions (e.g., malignancy or inflammatory conditions) increasing their 1 year mortality. However, at 3 and 5 years follow-up, we do see increase in mortality with increasing BMI levels likely related to increase in the burden of cardiovascular events.

**Discussion:** We implemented classification, prediction, and natural language processing techniques in multiple scenarios to create and to analyze a highly complex and large cohort. This cohort recapitulates many findings from traditionally ascertained cohorts while enabling additional analyses (e.g., utilizing physician notes or richer temporal data), illustrating its utility for a variety of discovery efforts.

Using Patient-Centered Technological Design to Improve Inpatient Fall Prevention

Zachary Katsulis¹, Waiyin Leung, MS², Awatef Ergai, PhD¹, Laura Schenkel¹, Amisha Rai, PA-C⁴, Jason Adelman, MD⁴, James Benneyan, PhD¹, David Bates, MD²,³, Patricia C. Dykes, PhD RN²,³

¹Healthcare Systems Engineering Institute at Northeastern University, Boston, MA; ²Brigham and Women’s Hospital, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Montefiore Medical Center, Bronx, NY

Introduction: Falls are a serious patient safety issue. Each year, somewhere between 700,000 and 1,000,000 people in the United States fall in the hospital.¹ Hospitalized patients are especially at increased risks for falls and fall injuries.² Most of these falls, however, are considered “preventable” by the Centers for Medicare & Medicaid Services (CMS).³ An earlier study we conducted tested a FALL TIPS (Tailoring Interventions for Patient Safety) Toolkit that used HIT to link routine nursing fall risk with evidence-based interventions to prevent patient falls. The study demonstrated that fall rates were reduced by 22% in intervention units and the toolkit was particularly effective with patients aged 65 years and older.⁴ Based on previous findings, an extension project funded by the Agency for Healthcare Research and Quality (AHRQ), called the Patient-Centered Fall Prevention Toolkit, seeks to use a patient-centered approach to improve inpatient fall prevention through the use of existing iPads at the patient’s bedside. Keeping human factors analysis in mind, patient surveys were conducted at two hospitals serving different socio-economic populations to understand how demographic factors might affect patients’ openness or perceived ability to use technology at the bedside. Using these results we aim to develop an initial patient-centered electronic prototype that accommodates all users in achieving the safest care.

Methods: We conducted patient surveys in pilot units participating on our Patient Safety Learning Labs project (e.g. oncology units at Brigham and Women’s Hospital (BWH) and medicine/surgical units at Montefiore Medical Center (MMC)). Three of the survey questions, seen in Figure 1, related to the patient’s openness, ability, and use of technology. A five point Likert scale was used, with increasing agreement or hours of use corresponding to the increasing scale. Demographic information including age, ethnicity, and highest level of education completed were collected. We compared user preference by analyzing the difference in responses between BWH and MMC, as well as between older (65 or older) and younger patients (less than 65). Due to the inability to assume normal distribution, the comparison of response means between older and younger patients was conducted using a two tailed T-test; whereas a two tailed Z-test was used to compare response means between BWH and MMC (N>30 for each group). Calculated p-values were used to determine significant difference (p-value<0.05) between means.

Results: Table 1 presents the three technology-related patient survey questions along with their calculated p-value and corresponding group means at MMC and BWH. Of these three survey questions, the two patient age groups showed significant difference (p-value = 0.0117 < α = 0.05) for only question 11 at BWH. Figure 1 shows the disparity in demographics between the patient populations at the two hospitals. In addition to demographics, roughly 46% of patients at MMC received some form of higher education (some college or greater) in comparison to 76% of patients at BWH. Table 2 showcases there was no significant difference between patient openness, ability, and average use of technology despite the disparity in ethnicity and education level at the two hospitals.

Discussion: At BWH, older patients reported that they are more likely to be less open to using an electronic device in their care plan than younger patients. This same trend was seen at MMC but was not significant. We believe this to be due to the small sample of older patients and we would expect to see the same trend given a greater sample size. We believe it may be beneficial to consider involving family members in using HIT for fall prevention particularly for frail senior patients, as caregivers (often younger and not functionally impaired) can play an important role but are often overlooked targets for expanding portal use at the bedside.⁵ Based on our data, we believe that on our target units, ethnicity and education level will have no significant impact on the openness, ability, or average use of an electronic device, such as an iPad, in their care plan. This supports prior research that blacks and whites have nearly identical rates of smartphone ownership and use, despite a previous “black/white ‘digital divide’”⁶ Using these survey results and patient feedback, we will continuously engage patients in the iterative design process of our iPad application with the ultimate goal of increasing usability and decreasing inpatient falls.

Identifying and Understanding Data Quality Issues in a Pediatric Distributed Research Network

Ritu Khare, PhD\textsuperscript{a}, Levon H. Utidjian, MD\textsuperscript{a}, Greg Schulte, MS\textsuperscript{a}, Keith Marsolo, PhD\textsuperscript{c}, L. Charles Bailey, MD, PhD\textsuperscript{a}

\textsuperscript{a}Children’s Hospital of Philadelphia, Philadelphia, PA, \textsuperscript{b}Children’s Hospital Colorado, Aurora, CO, \textsuperscript{c}Cincinnati Children’s Hospital Medical Center, Cincinnati, OH

Introduction
Collaborations across multiple institutions are very essential to achieve adequate cohort sizes in pediatrics research\textsuperscript{1}. PEDSnet is a newly established clinical data research network (CDRN) that aggregates electronic health record (EHR) data from eight of the nation’s largest children’s hospitals\textsuperscript{2,3}. With the ultimate goal of supporting a variety of comparative effectiveness research, a prerequisite in PEDSnet is to ensure that the network’s data is “high quality.” The prominent challenges include the lack of EHR data’s fitness for immediate research use, semantic heterogeneity across systems, and data peculiarities in pediatrics\textsuperscript{1,4}. While previous studies have presented frameworks and techniques to validate the EHR-derived data, the process of data quality assessment in CDRNs continues to remain “behind the scenes” with no published empirical results\textsuperscript{4,5,6}. In this study, we implement a comprehensive set of validity checks in PEDSnet to identify, understand, and report a range of data quality issues (see Table 1)\textsuperscript{4,6}.

Methods
The PEDSnet network uses the OMOP Common Data Model (CDM), a widely accepted schema for observational medical data\textsuperscript{7}. Each partner site prepared an instance of the CDM by performing the extract-transform-load (ETL) operations from its EHR according to network-wide conventions. In this study, we focused on attribute-level data quality assessment\textsuperscript{5}, and developed data analysis scripts to ensure adherence to the CDM, perform data domain checks, and compute frequency distributions\textsuperscript{6}. The output report comprises a visual summary (e.g. bar graphs) and a list of automatically detected data quality issues (e.g. out-of-range values) for each attribute. We executed the scripts on each site’s data, and reviewed the graphs to identify additional issues (e.g. unusual shape or peaks). Next, we classified each issue as an “ETL issue” that could be resolved by fixing the ETL logic or a “provenance issue” that exists due to an anomaly, data characteristic, or an error in EHR\textsuperscript{9}. Finally, each issue was communicated to the originating site, which was responsible for validating the cause of the issue and resolving the issue.

Results
At the current stage of this project, we have collected data from all partner sites (total 8), representing 4.4 million children and over 75 million encounters. Table 2 organizes the total number of issues by various data quality dimensions. The fidelity dimension corresponded to the cases where the distribution of the EHR values did not match with that in the CDM, due to ETL errors or due to data characteristics, such as differences in granularities between the coding systems used in the source (e.g. ICD-9) and the CDM (e.g. SNOMED CT). The consistency dimension included the cases where the attribute values were not aligned with the conventions (ETL issue), or were abnormal, e.g. a gestational age value greater than 42 weeks (provenance issue). The accuracy dimension included discrepancies between sites, e.g. significant differences in variation of body weights. Finally, the feasibility dimension corresponded to missing data in the EHR or incomplete ETL mappings.

Discussion
A key challenge in building a CDRN is to define and achieve an optimal degree of data quality. In this study, we have conducted a data quality assessment of the PEDSnet network using rigorous data checks and manual reviews of statistical plots. While this study only focused on attribute level analysis, we have learned several important lessons. In spite of defining network-wide conventions, hosting a shared repository of ETL scripts\textsuperscript{8}, and organizing regular web conferences across sites, we identified over 320 data quality issues across three sites. This strongly suggests that proactive project management and documentation are not sufficient to ensure data validity in a CDRN. We judged nearly 37% of the identified issues as ETL mistakes, and despite the diversity of experiences and backgrounds of various teams, the site-wise contributions to these issues were significantly similar. This reinforces that a formal data quality assessment process is critical in building a CDRN. Our future work includes operationalizing advanced assessment levels\textsuperscript{5}, extending to more clinical domains, and reporting longitudinal results.

Evaluating the Effects of Cognitive Support on Interpreting ICU Patient Data

Peter Killoran, MD^1,2; Swaroop Gantela, MD^1; Sahiti Myneni, PhD^1; Khalid Almoosa, MD^2; Bela Patel, MD^2; Thomas G. Kannampallil, MS^3; Vimla L. Patel, PhD^4; Trevor Cohen, MBChB, PhD^1.

^1School of Biomedical Informatics and ^2School of Medicine, The University of Texas Health Science Center at Houston, Houston, TX. ^3College of Medicine. University of Illinois at Chicago, Chicago, IL; ^4New York Academy of Medicine. New York, NY.

**Introduction**: Clinicians’ attention is a precious resource, often consumed by the need to aggregate and synthesize information while making clinical decisions^1^. Cognitive Support Systems (CSS) seek to mitigate these cognitive burdens while also enhancing the clinical comprehension necessary to make decisions^2^.

In this work, we characterize the effects of a CSS (SIRSi) designed to organize ICU data in accordance with frameworks of expert clinical decision making regarding Systemic Inflammatory Response Syndrome (SIRS). SIRSi organizes relevant information along “intermediate constructs” – diagnostically and prognostically relevant clusters of clinical information that are representative of experts’ knowledge organization^3^.

In this study, we describe the effects of SIRSi on clinical comprehension based on the analysis of verbal (“think-aloud”) protocols produced by 19 participants (3 Attending and 16 Resident physicians).

**Methods**: SIRSi’s architecture includes web application and knowledge engine servers for executing semantic queries using a custom ontology to retrieve data from MIMIC-2, a de-identified ICU database^5^ (see ^3^ for further details). Our experimental design involved creation of two different interfaces for viewing the same data, one organized by “intermediate constructs” (Concept), and the other organized by data source, as is typical in most contemporary Electronic Health Record systems (Control) (Figure 1). Two patient cases of similar acuity were viewed by each subject after reading a short vignette summarizing the patient’s clinical condition. Assignment of the case to the interface (Concept vs. Control) and the viewing order were randomized for each subject. Subjects then completed a think aloud protocol (in the tradition of ^6^) as they viewed patient data. Participant verbalizations were transcribed, coded, and both the order and frequency of data element mentions were extracted. While data were normalized for all data elements within a given subject, our analysis focused on how subjects attended to data concerning the criteria for SIRS (PaCO2, Respiratory Rate, Heart Rate, White Blood Cell Count, and Temperature). Of note, criteria for SIRS were objectively met for both patient cases.

A transition probability matrix, representing the sequences of transition across data elements was also generated.

**Results**: As expected, the order in which each data element was considered closely followed the interface layout. Participants generally followed a linear, top-down viewing order for both the Concept and Control views (Figure 2). However, attention to the SIRS criteria, a critical component of SIRS-related decision making, was greater for 18/19 participants when using the Concept view. Comparison of the frequency with which SIRS-related variables were mentioned across all participants also showed significantly more attention to SIRS criteria when using the Concept vs. the Control interface (paired t-test, t(18)=4.12, p<0.001). Of note, six out of the nineteen participants using the Control interface did not mention the PaCO2, and two of these did not mention respiratory rate, indicating that they had not adequately assessed the respiratory status of the patient. All six of these participants showed better performance using the Concept interface, as suggested by greater attention to the SIRS criteria, with only one participant failing to mention respiratory rate when using the Concept view.

**Discussion**: Participants generally attended to information in the order in which it was presented. These results are consistent with previous work showing that the layout of information in a clinical display has a significant impact on its interpretation^1^.

Furthermore, our findings show significantly greater attention to SIRS-related data variables with cognitive support. These findings suggest that in the context of complex clinical data associated with critically ill patients, CSS offer advantages over traditional information displays. Future work is needed to validate these findings in real clinical settings.

A Framework for Person-centered, Community-wide Care Coordination

Katherine K. Kim, PhD, MPH, MBA1, Janice F. Bell, PhD, MPH, MN1, Charles Boicey, MS, RN-BC, CPHIMS2, Janet Freeman-Daily3, Susan Hull, MSN, RN-4, Anna McCollister-Slipp5, Jill G. Joseph, MD, PhD1

1University of California Davis, Sacramento, CA; 2State University of New York Stony Brook, Stony Brook, NY; 3Seattle, WA; 4Wellspring Consulting, Healdsburg, CA; 5Washington, D.C.

Introduction and Objective

The increasing prevalence of complex chronic conditions such as diabetes, heart disease, and cancer is of great concern. Health care is fragmented and involves diverse participants and resources, pointing to the need for community-wide care coordination (CWCC). While technology may help, little is known about the specific coordination challenges for individuals or about the dynamic nature of coordination across teams and timespans.

Materials and Methods

Content analysis was applied to publicly available data from a one-hour #HCLDR tweetchat held on 10/28/2014. Data were collected from three Twitter search engines to assure complete data capture. 1569 tweets and retweets were posted by 134 participants. 108 tweets pertained to the question “What are the most important challenges that patients, family members, caregivers face in coordinating care?” A framework was developed from literature review1,2 and content analysis. The study team included patients, clinicians, researchers, and informaticists.

Results

The five most frequently mentioned themes are related to patient, family, caregiver challenges and needs in care coordination include: layers and silos of care (25%), data sharing (17%), verbal communication (13%), shared care planning (10%), and family, caregiver needs, expectations, burdens (9%). These data highlighted requirements for HIT to address multiplicity of relationships, dynamic vs. static states, and comprehensive vs. compartmentalized information. Examples of HIT functions for these needs, mapped to themes are suggested (Table 1). The CWCC conceptual framework offers a way to organize HIT functions to assure these needs are addressed. Domains 1-3 are principles while 4-6 indicate dynamic states requiring coordination.

1. Person-centered Coordination: Empower individuals to exercise autonomy, collaborate in decision making, and optimize coordination. Support teams in delivering coordination activities that respond to individuals’ values, needs, and preferences.

2. Shared Care Planning: An inclusive (of individual, family teams, healthcare teams, and/or community teams as appropriate) process of comprehensive assessment, goal-setting and planning, implementation, and evaluation of an individuals’ course of health over the lifespan. The resulting documentation, a shared care plan, may have greater detail on shorter time periods when intensive focus is necessary.

3. Health Information Technology Enablement: Help individuals and teams fulfill CWCC activities with the information and tools to achieve individuals’ health goals, efficiently manage groups of patients, contribute to population health goals. Enable coordination at points of need.

4. Within teams: Three types of teams are family teams, healthcare teams, and community teams. Within each team there are certain roles and responsibilities, specific activities that regularly occur, particular information that is helpful, and unique workflows.

5. Across teams: The individual, family teams, healthcare teams, and community teams interact with each other. The interactions among teams vary in depth and breadth.

6. Over time: CWCC perspective on time is over the continuum of care, and the lifespan of a person. Different teams are active at different times, and the level of participation also varies.

Discussion and Conclusion

Discussions about the need for CWCC must enable dynamic collaboration, be flexible to support changing informational needs, and adapt to multi-setting, multi-team workflows. Mobile applications and social networking technologies can be used to tailor data collection and display while supporting user-driven communication. These applications should be integrated with electronic health records and personal health information tools.

Representing Nursing Content within a Multi-Disciplinary Terminology

Tae Youn Kim, PhD, RN1,2, Nicholas Hardiker, PhD, RN2,3, Penni Hernandez, ND, RN4, Jane Millar4

1University of California Davis, Sacramento, CA, USA
2International Council of Nurses, Geneva, Switzerland
3University of Salford, Salford, UK
4International Health Terminology Standards Development Organisation, Copenhagen, Denmark

Introduction
The International Classification for Nursing Practice (ICNP) is a logic-based nursing terminology developed by the International Council of Nurses (ICN) to support the documentation and exchange of nursing data worldwide.1,2 As SNOMED® CT is considered to be one of the most comprehensive multi-disciplinary terminologies for healthcare, the representation of nursing domain knowledge within SNOMED CT is critical if the terminology is to capture a holistic view of healthcare. Under a collaboration agreement between ICN and the International Health Terminology Standards Development Organisation (IHTSDO),3 the authors agreed work to build linkages for nursing diagnostic/outcome concepts, working with the IHTSDO Nursing Special Interest Group (SIG) to ensure broader involvement of the profession. The objective of this work was to facilitate a transformation pathway between ICNP-encoded data and SNOMED CT, to ensure that nursing continues to be reflected in global multidisciplinary healthcare information systems. This involved a gap analysis and production of an equivalence table.

Methods
A series of activities were undertaken to identify and validate equivalences within SNOMED CT for the 783 pre-coordinated diagnosis or outcome statements within the 2013 release of ICNP, drawing together the results of previous work: 1) pre-existing equivalencies4 within the Unified Medical Language System (UMLS) maintained by the U.S. National Library Medicine5; and 2) candidate equivalencies identified manually for the remaining statements.6 The combined equivalency table was then validated by the IHTSDO Nursing SIG. Any disagreements were further discussed with the ICN eHealth team and IHTSDO terminologists until consensus was reached. Work began in 2011 and has continued through various releases of both terminologies.

Results
The first two steps yielded 196 equivalencies within UMLS and 175 from the manually identified equivalencies. Following validation, there were a total of 336 equivalencies (43% of the total number of ICNP statements). Certain nursing diagnosis/outcome statements within ICNP are negative in nature (relating to illness) (n = 535), while others are positive (relating to wellness) (n = 248). Coverage within SNOMED CT for negative ICNP diagnosis/outcome statements was encouraging (62%). Positive statements represented a large proportion (55%) of the complete set of unmatched concepts (n = 447).

Discussion
The value of this work extends beyond a simple assessment of content coverage. As a result of the activity 126 new concepts have been added to SNOMED CT (January 2015 release). For example, a new concept ‘deficient knowledge of symptom (finding)’ were added to SNOMED CT as an equivalent to the ICNP concept ‘lack of awareness of symptoms’. The validation activity has served also to enhance significantly the quality of both terminologies, for example through greater clarity of meaning for individual statements. For instance, the ICNP concept ‘effective verbal communication’ was renamed to ‘able to communicate verbally’ (in line with SNOMED CT syntax) as the adjective ‘effective’ in ICNP is semantically equivalent to ‘able to do’ (note that any changes in either terminology can be tracked through their respective history mechanisms). Finally, the validation activities (in addition to activities around the identification of equivalencies) have resulted in an effective way of working that will support further planned work between IHTSDO and ICN on the representation of nursing interventions within SNOMED CT. Both terminologies continue to evolve and the collaborative work is ongoing. The updated results for the most recent releases of ICNP (2015 release) and SNOMED CT (July 2015 release) will be presented at the conference.

Evaluating the Accuracy of Automated Notifiable Condition Detection in Free-Text Electronic Laboratory Report Results Using Contemporary Text Mining and Machine Learning Methods

Uzay Kirbiyik, MD, MPH\textsuperscript{1,2}, Patrick T. Lai, MPH\textsuperscript{2,3}, Brian E. Dixon, MPA, PhD\textsuperscript{1,2}, Shaun Grannis, MD, MS\textsuperscript{2,4}, Suranga N Kasthurirathne, BEng\textsuperscript{2,3}

Introduction

Electronic Laboratory Reporting (ELR) refers to the process of electronically transmitting laboratory reports that identify reportable conditions from laboratories to public health stakeholders, and has been shown to improve timeliness and completeness of disease reporting.\textsuperscript{1,2,3,4} The volume of electronic reporting to state agencies is expected to increase given Stage 2 “meaningful use” program incentives from the U.S. Centers for Medicare & Medicaid Services that require eligible hospitals and encourage eligible providers to submit notifiable disease laboratory results to public health agencies using ELR.\textsuperscript{5} However, the process of identifying positive cases typically requires human review which takes time and it is infeasible both for clinical providers to manually review increasing volumes of plaintext laboratory reports and also for health departments to sift through all potentially reportable items to identify true cases. Here we demonstrate an approach for automatically identifying notifiable disease from plaintext electronic laboratory results using Salmonella as an exemplar condition.

Methods

We received 1,586 ELR’s for Salmonella through our notifiable condition detector (NCD) system from August 1\textsuperscript{st}, 2010 to July 31\textsuperscript{st}, 2012. A total of 286 unique laboratory result messages were identified after removing duplicates. We manually reviewed these laboratory messages and labeled them as either positive or negative for Salmonella. Informed by methodology developed by SNK, we removed stop words and stemmed the remaining words to identify a complete list of single-word tokens from all reports. For convenience, only tokens with an overall frequency of 3 or higher were retained and analyzed using Weka (figure 1).\textsuperscript{6} We used an information gain feature selection method\textsuperscript{7} to first rank and select tokens. We then evaluated logistic regression and random forest classifiers using the selected feature (tokens) using 10-fold cross-validation for testing the models.

Results

Text mining of 174 manually-reviewed positive and 112 negative ELRs revealed 1,102 unique tokens (out of 10,826 words). Further filtering revealed 333 tokens for our final set. After ranking by information gain, we choose the first 4, 10, 19, and 38 tokens for analysis. Our results show both random forest and logistic regression classifier methods successfully predicted the report results compared with manual review (Table 1).

Discussion

Both models exhibit higher accuracy than the current operational notifiable condition detection (NCD) system.\textsuperscript{8} Thus we conclude that it is both feasible and effective to apply text mining methods and machine learning approaches to support automated detection of public health notifiable diseases. The standard language and focused vocabulary used in the results sections may contribute to the high accuracy observed, and thus our future work will seek to evaluate the effectiveness of these methods across several other high-value notifiable diseases. These results suggest an automated system for ELR result decisions is promising; quicker and improved accuracy of automated disease detection will help not only public health and clinicians but hospital systems for their reports and planning.
Figure 1. An overview of our analysis of the notifiable disease reporting system. Lab results are transmitted via the HIE to the notifiable condition detector (NCD). Lab report transactions indicating a salmonella test were then sampled and manually labeled as positive or negative. The reports were preprocessed and discriminating tokens selected. Tokens served as features in both logistic regression and a random forest decision models, and their accuracy evaluated.

Table 1. Change on the model accuracy with the number of tokens included. Tokens were grouped based on clustering of their rank scores.

| Model accuracy | Classifier: | | | Classifier: | | |
|----------------|------------|------------|------------|------------|------------|
| Tokens used    | Logistic   | Random      | Logistic   | Random      |
|                | Sensitivity| specificity| ROC        | Sensitivity| specificity| ROC        |

Abstract
In this study we develop a text processing and reporting tool that processes clinical notes and identifies ill-formed constructions and extracts medical named entities. The medical named entity extraction score improves when the ill-formed constructions are identified and eliminated from the test dataset. We take cues from social media analytics studies and employ supervised machine learning algorithms and several rule based engines.

Introduction
Clinical notes have been analyzed in greater detail to harness important information for clinical research and other healthcare operations, as they depict rich, detailed medical information. For example, entity extraction systems process clinical text and extract instances of named entities that can be further grouped into specific semantic categories [1], [2], [3] and others. However, there is no significant study or analysis of processing ill-formed sentences in medical notes toward developing a system that identifies ill-formed constructions. Authors in [4] provide guidelines for parsing clinical text based on an annotated corpus to process syntactically ill-formed sentences. Other approaches such as [5] and [6] focus on increasing the robustness of the parser by enhancing accurate semantic representation. Also, there has been some work done in the field of social media on ill-formed text. Authors in [7] analyze Twitter data for text normalization using SVM and heuristic-based methods. We present an exploratory study into (1) identifying ill-formed constructions and (2) preparing a medical report based on clinical documents. The ill-formed identification module extracts text that is syntactically incorrect. The medical reporting module produces medical named entities (MNEs) that are presented chronologically in a tabular format. In this study we show that the MNE extraction scores improve if we identify ill-formed constructions in the input text. We define ill-formed constructions as constructions that are syntactically and typologically incorrect. For future work, we plan to improve the identification score and normalize the ill-formed phrases to correct phrasing.

Method
Data. We collected clinical notes - patient discharge summaries and doctor’s notes from i2b2 datasets (https://www.i2b2.org/NLP/DataSets/). We divided the datasets (2100 sentences) into randomly selected 70/30 splits for training and testing respectively. All text documents were tokenized into sentences for further processing. These sentences were manually annotated by a physician for three categories: (1) MNE-m – medical entity depicting medication; (2) MNE-s – medical entity depicting symptoms; (3) MNE – all other medical entities.

MNE Extraction. We use a combination of machine learning classifiers along with some rule-based methods. We developed a supervised linear-chain Conditional Random Fields (CRF) model based on the Stanford Named Entity Recognition (NER) system using 10-fold cross validation on the training set data. All the previously mentioned classification categories are encoded with the Begin-Inside-Outside (B-I-O) scheme. We extracted lexical and morphological features (n-gram tokens), syntactic features from the parse and dependency trees. In case of multiple MNEs, we selected MNE closest to the time entity in the parse tree. We curated a dictionary of medical phrases and abbreviations from UMLS and SNOMED CT and on-line resources (http://www.delmarlearning.com). Additional features (from [8]) specific to dosage such as mode feature set, frequency feature set etc. were also used.

Ill-formed Text Handling. In addition to the previously curated dictionary, we used aspell (http://aspell.net/) to decide outside-of-vocabulary (OOV) and inside-vocabulary (IV) terms. We extracted dependency graph features from a parse tree, in addition to N-gram features. Contextual features were key to understanding the ill-formed tokens. In addition, we modified a linear kernel SVM liblinear [9] for making decisions on ill-formedness. For ill-formed constructions, tokens which were not part of the dictionary were considered ill-formed. Also, word patterns which have periods like “p.o. q. day” were considered as IV, because they may be representing dosage etc. Similarly, words with #,@,/ like “Insulin 70/30” etc. were also considered as IV. An example of OOV constructions is: She was initially continued on Cipro/Zosyn.
**Experiment Design.** We designed three experiments using the I2B2 dataset. In the first experiment using ill-formed identification module we extracted ill-formed text from the input text. In the second experiment we extracted MNEs without extracting out the ill-formed constructions. In the third experiment we manually eliminated the ill-formed constructions first, and then processed the ‘clean’ text using the MNE extraction module.

**Results**
An illustration of MNE extraction output is given in the Table 1. For paucity of space we only show MNE extraction and not MNE-m or MNE-s extractions.

**Input Text:** September 11, 1994, coronary artery bypass surgery. He came to the emergency room with chest pain on July 22, 1994, relieved with sublingual nitroglycerin. The patient in September of 1993 had 3-4 millimeter ST segment elevation in V1 through V4 and depression in II, III, and AVF.

Preliminary results of this study are depicted in Table 2. We use standard Recall, Precision and F-score as evaluation metrics. The first column in Table 2 depicts MNE extraction for dataset for which ill-formed-sentences are not identified and eliminated (Experiment 2). The second column gives MNE scores for the dataset for which ill-formed construction are eliminated (Experiment 3). The third column provides performance of medical entity extraction by Patrick and Li [8]. The fourth column provides ill-formed identification and extraction scores (Experiment 1). We compare this work with [8] because they record highest overall precision in the extraction of phrase level horizontal evaluations category in the I2B2 2009 medication challenge and the method is very similar to our work.

**Discussion**
In this study we developed a medical reporting tool that extracts medical named entities and presents them in tabular format along with respective dates. Prior to extracting MNEs, this tool identifies and extracts ill-formed constructions in the input clinical notes. We show that fixing the ill-formed construction in the input dataset will yield better medical entity extraction results. However, our MNE module failed to identify longer NP strings (longer than 3 tokens) and NPs that are rarely encountered in the training set. For ill-formed text, the system does not identify medically ill-formed constructions (abnormal dosages, wrong medication and procedures etc.). In the future we will analyze ill-formed constructions with medical inadequacies and recommend possible correct options.

Human Factors of Health Information Exchange: Barriers and Facilitators to Use of the VA’s CPRS and a Regional Health Information Exchange

Andre W. Kushniruk, MSc, PhD, FACMI1, Elizabeth M. Borycki, RN, MN, PhD1, Helen Monkman, MA1, Kenneth Boockvar, MD, MS2

1School of Health Information Science, University of Victoria, Canada; 2James J. Peters Veterans Affairs Medical Center, Bronx, New York

Introduction

Currently, worldwide there is an increasing demand for interconnection between electronic health records and regional databases and health information exchange organizations (RHIOs)1,2. The issue of how to evaluate such integration among dissimilar systems from a human factors perspective has arisen and is addressed in this podium presentation. Issues related to usability and workflow have been noted3,4,5. In addition, it has also been noted that if not done carefully, integrating systems may inadvertently lead to errors in using and interpreting information across those systems6. The objective of this study was to observe providers’ use of VA’s CPRS in conjunction with use of a RHIO tool (which were loosely integrated, requiring users to switch between the CPRS and the RHIO tool) to identify system and provider factors that impede and facilitate adoption of information exchange for routine use.

Methods

IRB approval was obtained and 12 healthcare providers were observed as they interacted with the VA’s CPRS while accessing information from the Bronx RHIO. The protocol involved audio recording the providers’ interactions with both systems in a natural environment, e.g., an office or hospital meeting room while they interacted with their own patient cases. Two observers took notes regarding what screens, system components and systems (i.e. CPRS or RHIO) were used. Participants entered data into the patient record system while “thinking aloud” or “verbalizing thoughts” in deciding on a course of action. Sessions took 30-50 minutes per participant. The resulting think-aloud protocols were audio taped, transcribed verbatim and linked in time with the record of participant-computer interactions. A coding scheme was developed to analyze the transcripts. Using multiple close readings, investigators performed initial independent coding of each transcript, generated a list of concepts and a coding scheme. Codes were then reviewed to determine if additional codes were necessary (e.g. RHIO understandability, content issues etc.). Content analysis was conducted and themes in the transcripts were identified.

Results

Analysis of the log files indicated a number of recurrent themes. In majority of the transcribed sessions, issues around participants having difficulty remembering their passwords and login to the RHIO prevented regular use of the RHIO. Other emergent themes included the perceived desire to have more data available in the RHIO (e.g. a more complete listing of out-patient medications and discharge summaries) to make the time expenditure for using it justified. The need for improved integration between the CPRS and the RHIO (i.e. not requiring users to switch between systems) was noted by a number of participants. Others indicated the need to improve the usability and organization of the information contained in the RHIO, including removing duplicate information and allowing for cut and paste features that would retain formatting. All participants indicated the need to streamline the interface and workflow to reduce time taken to access the RHIO through more seamless integration between systems when working with a heavy patient load. Another suggestion was for regular notification of improvements to the RHIO.

Discussion

Using our methodological approach (borrowing from human factors research) we found substantial barriers for VA providers in the course of using or trying to use a RHIO Exchange interface while using the CPRS. For some provider participants, these barriers outweighed the usefulness of the RHIO and they did not use the RHIO in the course of routine clinical care. In contrast, a minority of providers felt that the information in the HIE was important so they used the RHIO no matter what the workflow barriers were. These findings are being used to optimize the integration between the CPRS and the RHIO, as the method taken has been able to identify specific key barriers that can be targeted for removal in future iterations, with improved integration expected to lead to greater usability.

Collection and Documentation of Sexual Orientation and Gender Identity Demographic Data in the Electronic Health Record: The Patient Perspective

Brandyn D. Lau, MPH, CPH1,2,3, Laura Vail, MS2, Lisa M. Kodadek, MD1, Ryan Y. Shields, BA1, Danielle German, PhD3, Susan Peterson, MD1, Adil Haider, MD, MPH4
1Johns Hopkins School of Medicine, Baltimore MD; 2Armstrong Institute for Patient Safety and Quality, Baltimore MD; 3Johns Hopkins Bloomberg School of Public Health, Baltimore MD; 4Center for Surgery and Public Health, Brigham and Women’s Hospital, Boston, MA

Abstract
We assessed patient perspectives regarding collection and documentation of sexual orientation (SO) and gender identity (GI) demographic data in the electronic health record (EHR). Patients are more willing to report their SO and GI when all patients are routinely asked using standardized tools, and allow these data to be stored in EHRs if security and privacy concerns are addressed, and protections and training are in place to ensure appropriate information use and attention by providers.

Introduction
The Institute of Medicine and The Joint Commission have endorsed routine collection of sexual orientation (SO) and gender identity (GI) demographic data in clinical settings to better understand the health of lesbian, gay, bisexual and/or transgender (LGBT) patients.(1,2) While there is an abundance of expert opinion regarding the collection, documentation, and use of SO and GI data in the electronic health record (EHR), patient perspectives are largely unexplored. (3,4) The purpose of this study is to assess patient perspectives related to collection and documentation of patient SO and GI demographic data in the EHR and the use of these data within hospital emergency departments (EDs).

Methods
A purposive sample of participants was recruited for one-on-one in-depth interviews. Participants were recruited through community outreach, flyers, and social media. A semi-structured interview guide was developed by an expert panel of patients, community activists, and healthcare providers. Individual interviews were conducted by one of two researchers and audio data were subsequently de-identified, transcribed, and independently coded using the constant comparative method common to grounded theory. This study was funded by Patient Centered Outcomes Research Institute (PCORI) and approved by the Johns Hopkins Medicine Institutional Review Board.

Results
Fifty-three patient participants were interviewed including 9 lesbian, 12 gay, 12 bisexual, 2 queer, 14 straight and 4 participants who identified as pansexual, asexual or unsure; 16 of the 53 participants identified as transgender, bigender or genderqueer. Participants ranged in age from 22 to 67 (mean age 41.8 years) and 42% were white (non-Hispanic). Three main self-reporting tools were identified for collecting SO and GI demographic data from patients in the ED: paper form, electronic kiosk, and cellphone app. Patient perspectives regarding reporting of SO and GI demographics were categorized into six major themes: privacy, medical relevance, normalization, recognition, patient-provider relationship, and ED flow (Table 1). Participants were more willing to provide SO and GI demographic data when it is clear that all patients are routinely being asked in a standardized manner and when offered a rationale about why the information is needed and how the information will be used.

Recognition that SO and GI demographic data would ultimately be stored in the EHR made private reporting of this information on an electronic kiosk or smartphone app more appealing than verbal reporting during the clinical encounter. Patients commonly cited privacy concerns about storage of SO and GI demographic data within EHR systems, including access by third parties such as employers and insurance companies, as well as unintended disclosure to family and friends. Patients noted that documentation of SO and GI demographic data within the EHR may facilitate proper recognition of preferred name, pronouns, and relationships by providers throughout the ED encounter. Further, patients felt that self-reporting prevented the possibility of judgment or discrimination by the provider and alleviated the need to pre-judge the provider for cues to safety or acceptance of SO and GI minorities. Patients reported multiple benefits associated with electronic collection and documentation of SO and GI
demographics including the ability to update/modify their responses, use their own devices (e.g. cellphone app, patient portal), and having more control over own data. Commonly, patients cited privacy concerns with paper-based documentation of SO and GI demographic data due to less perceived monitoring than electronic methods.

Conclusion

Research surrounding the health status of LGBT individuals in the United States is limited because SO and GI data are not routinely collected nor documented in clinical settings. National organizations advocate for collecting these data from patients, but have offered little patient-centered guidance for the most appropriate methods for collecting, documenting, and using these data. This is the first study to ascertain patient perspectives regarding the collection and documentation of SO and GI demographic data in the ED. Our study suggests that patients are more willing to report their SO and GI demographics when this information is asked routinely as part of standard policy. Furthermore, patients are generally willing to allow their SO and GI demographics to be stored in EHR systems if security and privacy concerns are addressed and protections and training are in place to ensure appropriate information use and attention by providers. Furthermore, patients consider that asking these questions during intake signals that the ED recognizes and respects sexual and gender minorities. Future work will engage a national sample of patients to develop appropriate, patient-centered methods to collect SO and GI demographic data in EDs.

Rethinking Document Retrieval for Scientific Literature: A Learning to Rank Approach
Jesse M. Lingeman¹, Hong Yu, PhD²
¹University of Massachusetts Amherst, Amherst, MA, ²University of Massachusetts Medical School, Worcester, MA

Introduction

With the rise of natural language queries from smart phones, full document queries for article recommendation, prior art for patents, or document duplication, search needs have been moving towards longer queries. Search using a full document as a query makes it helps the user as they don’t have to guess which keywords to use or form complicated Boolean queries. However, previous work has shown that simply using an entire document as a query does not work well¹. A long document is too noisy and it is difficult to identify the important parts of a document. Previous work has used translation models²,³, collaborative filtering⁴, NLP techniques⁵, topic models⁶, and other approaches.

In this work we approach query document search from a learning to rank perspective. Learning to rank works as follows: An initial query is run to retrieve a subset of the corpus, and then a feature vector is generated between the query and each document in the subset. The feature vector is a list of measures relating the document to the query. Learning to rank algorithms then build a supervised model that ranks a set of judged documents.

The primary contributions of this study are as follows: 1) Introduce a novel recommendation task with its own unique challenges. 2) Provide a simple yet effective framework for crowdsourcing tasks that require a domain expert to perform. 3) Apply a learning-to-rank framework to the task of query document search.

Methods

We apply our model to a crowd-sourced dataset. Given the full text of an academic publication, we want to rank its citations in order of importance. We collected recent publications from PLOS journals and asked the authors to rank by importance 5 citations we selected from their recently published paper. In total we collected 90 fully annotated publications. For each document and its citations we calculate text similarity features, citation position features, and the age of the citation. Citations were ranked using the LambdaMART⁷ implementation in the RankLib package from the Lemur toolkit⁸ and with SVMRank⁹. Normalized discounted cumulative gain (NDCG) is used as our performance metric. NDCG penalizes incorrect ranking of highly relevant documents more harshly than less relevant document.

Results

We first introduce two baselines: 1) a random baseline where we randomly shuffle the relevance judgments and 2) a model that uses the original pseudo-relevance judgments we used to select the citations to send to the authors. We find from testing that our random baseline has an average NDCG of 0.73. The data are split into 100 random train/test splits with 80% training data and 20% test data. SVMRank obtains an NDCG of 0.808 using the annotated data and 0.792 using the pseudo-relevance judgments (p < 0.05). LambdaMART obtains an NDCG of 0.81 using the annotated data and 0.75 from the pseudo-relevance judgments (p < 0.05). Feature selection is performed; with the best performing feature sets give SVMRank an NDCG of 0.824 using the annotated data and 0.808 using pseudo-relevance judgments. LambdaMART’s NDCG does not increase after feature selection.

Discussion

We have found that the learning to rank approach is effective for treating documents as queries. The model trained using the author’s judgments does significantly better than the model trained using the pseudo-relevance judgments.

We found that the most important features for both models are how frequently a citation is referenced in an article, the age of the citation, and the text similarity of the citation’s abstract with the discussion/conclusions sections of the article. The newer a citation is the more likely it is to be directly related to a the article rather than an older, more foundational citation, and restricting text similarity to discussion/ conclusion helps reduce noise in the document.

What we have shown is that the learning to rank approach, while requiring some feature engineering, can be applied to the task of query document search. In future work we will expand this approach to larger datasets across varied query document search datasets.

Identifying Novel Adverse Drug Events from Health Social Media Using Distant Supervision

Xiao Liu, PhD student¹, Hsinchun Chen, PhD¹
¹University of Arizona, Tucson, Arizona, United States

Introduction

Adverse drug events (ADEs) are a significant health problem worldwide. Many prior studies have extracted ADEs with supervised learning and unsupervised learning approaches. Distant supervision leverages existing knowledge and requires no manually labeled text for learning relations, which has not been explored for ADE extraction before. We develop a framework for identifying novel adverse drug events from social media using distant supervision. We utilize FDA’s Averse Drug Event Report System (FAERS) as a knowledge base for distant supervision and predict relations between medication and medical conditions in social media text.

Methods

Figure 1 shows the research method we propose for identifying novel adverse drug events from health social media using distant supervision. The data for this study comes from three sources: health social media discussion forums, Twitter, and the FDA’s adverse drug event reports from FAERS. We choose diabetes treatments as a research case to test the efficacy of our framework. We conduct data preprocessing with the following steps: medical entity extraction, co-reference resolution, and syntactic parsing. Medical entity extraction mainly aims to identify medical condition mentions and drug mentions health social media. Syntactic parsing generates features for distant supervision. We incorporate co-reference resolution to link medical entities across sentences within the same document. We develop our distant supervised learning for adverse drug event detection model based on the multi-instance multi-label assumption¹. We assume that each relation mention involving an entity pair has exactly one label, but allows pair to exhibit multiple labels across different mentions. It can be defined as a function that takes health social media data collection \(C\), a set of entity medical entity mentions extracted from \(C\) \(e\), and an extraction model, and outputs a set of relations \(R\) such that any relation extracted has at least one positive instance in \(C\). To train the model, we use FAERS as a knowledge base for drug indication and adverse drug event relations \(D\). Using distant supervision, \(D\) is aligned with sentences in \(C\), producing relation mentions for all relations in \(D\). EM algorithm is used to train the classifier. We evaluate our framework by held-out evaluation and manual evaluation. Held-out evaluation is conducted automatically by holding out part of the FAERS relation knowledge during training and comparing newly discovered relation instances against this held out data. We choose the single-instance single-label (SISL) model², and the multi-instance single-label model (MISL)³ as baselines for this automatic evaluation. This evaluation focuses on accuracy relation labels of each entity pair. For human evaluation, we evaluate the accuracy of relation labels on mention level. Among the 41 diabetes treatments, three of them were approved in the past two years: Afrezza in June 2014, Farxiga in January 2014, and Invokana in January 2013. We manually examine their top ranked relation labels.

Results

Table 1 shows a summary of the data after preprocessing. Overall, we retrieve about 17,000 sentences with at least one entity pair. These sentences contain 37 unique medication entities and 476 unique medical conditions.

Table 1. Summary of medication and medical condition mentions in data

<table>
<thead>
<tr>
<th>Medication</th>
<th>Medical Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>37</td>
<td>476</td>
</tr>
</tbody>
</table>
In Figure 2, we can see that MIML model has a larger area under precision-recall curve than MISL model and SISL model which indicates MIML model can predict relation labels with higher performance. This evaluation may under estimate the accuracy. If a true positive adverse drug event doesn’t exist in knowledge base, it will be considered as “no relation” in evaluation. Besides, some medical conditions and medications may have been reported to FDA but their mentions in health social media more often present “no relation”.

Figure 2. Precision recall curve for distant supervision

Table 2 shows the top ranked relations we found for Afrezza, Farxiga, and Invokana. Most of them are adverse drug events. These adverse events of medications new to the market can contribute to understand and assess the risk of new medications for both patients and clinical practitioners.

Discussions

In this research, we develop a research framework to identify adverse drug events from health social media using distant supervision. This is the first study that incorporates distant supervision in health social media ADE detection. By aligning knowledge base data with health social media data, we are able to generate a large number of data for training at low cost and the performance is promising. It can also help to evaluate the similarity and difference between health social media reports and FAERS reports. In the future, we plan to expand our research test bed to include more drugs. We will evaluate our approach with comparison to rule-based approach, and supervised learning approach for extracting adverse drug events.

Design Principles for Clinical Decision Support for Direct Use by Patients: Addressing Symptom Self-Management in Cancer Patients

David F. Lobach, MD, PhD, MS1; Janet L. Abraham, MD2; Donna L. Berry, RN, PhD2; Michael S. Rabin, MD2; Ilana Braun, MD2; Manan Nayak, MA2; Mary E. Cooley, RN, PhD2

1Klesis Healthcare and Duke University Medical Center, Durham, NC; and 2Dana-Farber Cancer Institute, Boston, MA

Introduction
Direct use of clinical decision support (CDS) by patients, particularly in the area of symptom management, has not been studied extensively. Only four studies described rule-based CDS tools for direct use by cancer patients.1-4 None of these studies has specifically focused on the patient barriers and clinician concerns that need to be addressed to create safe, effective CDS for patients. The purpose of this study was to identify information patients need and their preferences about being informed in order to create CDS that can empower and engage patients to self-manage their cancer-related symptoms. This study extends the literature by identifying design principles for creating CDS tools for managing cancer symptoms. We postulate that some of the principles we identified may be useful for developing CDS for patients across diverse clinical scenarios.

Methods
Our multi-disciplinary research team conducted a formative mixed methods study involving focus groups, semi-structured interviews, and usability surveys (Acceptability E-scale)5 with cancer patients, their caregivers and oncology clinicians. All focus group and interview discussions were audio-recorded and content was transcribed for analysis. We elected to focus on the most common symptoms contributing to emergency and urgent care visits among patients with cancer, namely pain, constipation, and nausea and vomiting.6 Based on the data gathered and on input from stakeholders participating on expert panels that included patients, caregivers, clinicians, information system developers, and administrators, we iteratively created prototypes suitable for display on desktop computers or mobile devices to simulate design and content features of a self-management CDS system for patient symptoms to which study subjects could respond. The conceptual framework of this project was informed by integration of the Technology Acceptance Model7, addressing system function and encompassing the perceived usefulness and perceived ease-of-use factors, with the refined version of the Chronic Care Model8,9, including elements of patient safety, cultural competency, care coordination, and community policies regarding community resources.

Results
For the formative evaluation, we recruited 24 cancer patients who had experienced the symptoms of interest within the past 6 months and 13 oncology clinicians from the Dana-Farber Cancer Institute. Through this design and evaluation process, we identified patient barriers and clinician concerns to using CDS for symptom self-management. To address these barriers and concerns, we formulated CDS design principles for patient safety, cultural competency, care coordination, resource availability, and system function (Table1). Patient usability surveys indicated strong support for the CDS tools.

Discussion
The findings from this study provide insight into how CDS systems can be developed to support patient self-management directly. Patient safety and tool navigation were critical features. Many of the insights gleaned from this study may be generalizable and could inform the development of CDS resources that patients with other diseases and their caregivers can use for self-management of symptoms. The barriers and concerns we identified for CDS for symptom management in cancer patients had both similarities and differences to barriers associated with self-management of non-malignant chronic conditions.10,11 Similar barriers included lack of knowledge, poor communication between patients and providers, and logistical issues for obtaining care. Other differences found in our study of CDS for cancer symptom self-management but not found in patients with non-malignant chronic conditions were patient safety, including the need to detect life-threatening problems and uncertainty about the safety of clinical recommendations; health beliefs that attribute negative connotations to certain recommendations; and issues related to CDS system function and navigation.

Conclusion
In this project, we identified design principles to enable creation of an evidence-based CDS that both engages cancer patients to self-manage symptoms using pharmacologic and non-pharmacologic therapies and clearly indicates when the patient should seek the help of a clinician.

Introduction

The surveillance of sexually transmitted diseases (STDs) is an important disease control activity of the Centers for Disease Control and Prevention (CDC). STDs contribute a significant burden of disease morbidity for Americans, even though they are largely preventable and treatable. Left undiagnosed and untreated, the costs can be high and include intractable pelvic inflammatory disease, infertility and infant death. Fifty-nine state and territorial jurisdictions report STDs that are on the list of national notifiable diseases to the CDC’s Division of STD Prevention (DSTDP). These diseases were responsible for over 1.8 million cases of infection reported to the CDC in 2013 (CDC, 2014).

STD Programs at the state and local levels report using electronic information systems for surveillance that meet the CDC’s NEDSS (National Electronic Disease Surveillance System) standards. For the past 25 years, DSTDP has supported the application STD*MIS for the states to use for this purpose. STD*MIS also provides functions for case management and partner services (PS). However, DSTDP is no longer supporting this system and the trend is towards interoperability across infectious disease reporting. Thus, states are migrating to integrated systems.

As of December 2014, 22 states and territories continued using STD*MIS to collect and transmit STD data for surveillance and PS; several others use it only for PS. These jurisdictions are in the process of selecting new systems, and many have requested advice and technical assistance from DSTDP. Of the jurisdictions not using STD*MIS, 10 used PRISM®, 7 MAVEN®, 3 TriSano® and 17 had custom made systems.

Methods

The study was designed to gather lessons learned about selection and implementation from states that have already transitioned to one of three off-the-shelf (OTS) systems, MAVEN®, PRISM® and TriSano®. Semi-structured interviews were conducted with STD program administrators for seven jurisdictions about their experiences selecting, contracting for and implementing a new information system for STD surveillance and program management. Selection of jurisdictions to be interviewed was based on recommendations from DSTDP staff who work with the local jurisdictions using the three systems of interest. The primary author had no previous experience with the interviewees or the systems under study.

Results

Phone interviews were conducted with 3 jurisdictions using MAVEN®, 2 using PRISM® and 2 using TriSano®. All of the jurisdictions had begun their transition to these systems in the last seven years with the most recent being in 2013. Respondents had been using custom database systems or STD*MIS prior to adopting the new system. The interviews covered selection and deployment, components and satisfaction, impact, and general lessons learned. Interviews were recorded in hand-written notes augmented by review of audio recordings. A case study was developed for each interview. The case studies were analyzed qualitatively to identify lessons learned. While two of the interviews were with one person involved in administering the STD Program, most of the interviews were with a group of people who were involved with the system either in the STD Program or as Information Technology (IT) support. General lessons learned across systems and implementations are summarized in Table 1 below. The data suggest that the differences between systems are more due to the implementation process than OTS. However, further study is needed to directly compare the functions and usability of each software package.

Conclusion

The experiences of public health department jurisdictions that have transitioned to new information systems in recent years, can inform others who are currently in the planning process. While individual systems may have their strengths and deficiencies, the process of adopting a new system can be managed in a way that improves the process of implementation and the impact of the deployment on data quality and program activities. Our results suggest that
jurisdictions take their time not only to plan for the implementation, but to develop relationships with IT departments and vendors, consider funding streams for maintenance of the system and prepare staff for new roles and responsibilities.

Leveraging Business Rules Techniques for Data Quality Assurance in Public Health Systems

David Lyalin, PhD and Warren Williams, MPH
National Center for Immunization and Respiratory Diseases (NCIRD), Centers for Disease Control and Prevention (CDC), Atlanta, GA, USA

Abstract
This presentation discusses a case study of implementing business rules for validating quality of data coming to immunization information systems that operate within U.S. state immunization programs. Independent evaluation findings indicate that application of developed best practice recommendations in state and local health departments resulted in improved data quality, reduced staff time, and increased efficiencies across immunization programs.

Introduction
This presentation discusses a case study of implementing business rules for validating quality of data coming to immunization information systems (IIS) that operate within U.S. state immunization programs. The accuracy, completeness, and timeliness of immunization records in IIS is a decisive factor in improving the health of patients, the operation of healthcare clinics, and public health decision making.

Methods
A panel of immunization experts has been assembled to develop consistent business practices for validating various streams of immunization and demographic data coming to IIS. Business rule technique in combination with concept modeling and other analysis techniques were successfully used during in-person facilitated sessions and teleconferences to discuss, formulate, and document consensus-based recommendations. Special attention has been paid to alignment between business strategies (principles – high-level direction) and business rules, as well as to actions on business rules violation and classification (grouping) scheme for business rules that follows combinations of key elements of the concept model, such as Patient Date of Birth, Vaccination Encounter Date, and Vaccine Type.

Results
Business rules helped to analyze immunization tracking operations and document consensus-based best practice recommendations for advancing quality of immunization data. The resulting best practices guide helps immunization information systems identify common errors in the incoming data streams using standardized business rules for validation checks and decision-making. Independent evaluation findings indicate that application of these best practice recommendations in the IIS domain of state and local health departments resulted in improved data quality, reduced staff time, and increased efficiencies across immunization programs. Most immunization programs (78%) were familiar with these recommendations; 76% of IIS used best practice guidelines. Users of the guide reported clear advantages to not “reinventing the wheel” – business rules that reflect best practices could be directly adopted or modified as needed, which resulted in reduced IIS staff time.

Discussion
Our experience indicates that collaboration among stakeholders and systematic analysis with business rules techniques promote system thinking and improves operations of the immunization registration area of public health. It also helps break otherwise complex programmatic and operational challenges into manageable fragments which can be incrementally improved upon.

Early Experiences with Meaningful Use and Online Portal Implementation among Providers/Staff and Patients/Caregivers in a Safety Net Healthcare System

Courtney Lyles, PhD, Lina Tieu, MPH, Dean Schillinger, MD, Neda Ratanawongsa, MD, MPH, Urmimala Sarkar, MD, MPH

University of California, San Francisco, Division of General Internal Medicine at San Francisco General Hospital, Center for Vulnerable Populations, San Francisco, CA

Introduction:
Online portals, which provide patients access to electronic health record information, are becoming ubiquitous in the US, especially with the support of Meaningful Use financial incentives. Because of their widespread implementation across many healthcare systems, portals will be the first health technology to reach many diverse patient populations across the country, and they will continue to be a platform through which we integrate future mHealth solutions (e.g., data from mobile phone apps and sensors) in the coming years. However, there is very little information about the reality of implementing portals in safety net systems that face higher numbers of competing demands and more limited resources. While our previous work has found high interest in electronic communication with providers among a diverse group of low-income patients in our healthcare setting, we sought to use qualitative methods to elucidate real-world experiences with portal implementation in the few months directly preceding portal implementation.

We conducted formative assessments with both providers/staff and patients/caregivers.

Methods:
This study took place within the San Francisco Health Network (SFHN), which includes 11 community-based primary care clinics as well as 4 hospital-based primary care clinics at San Francisco General Hospital. In this setting, the majority of patients served are low-income and publicly insured.

In 2014-2015, we conducted two rounds of data collection with both providers/staff and with patients: 1) a survey of 77 primary care providers and staff (January-February 2015), and 2) 16 in-depth interviews with chronic disease patients or their caregivers (from December 2013 to August 2014). The provider/staff survey was sent to all providers (physicians, nurse practitioners, nurses, medical assistants) and staff (front desk staff, etc.) in primary care across SFHN. This online questionnaire included closed-ended items about recommending portal use to patients as well as required open-ended items about expected barriers in using the system, particularly in using secure messaging through the portal. Patient interviews were focused on a more narrowly defined group of individuals who were most likely to use the portal website when it was launched in 2015: English speakers who expressed at least some interest in using the Internet for healthcare management (as the portal is not yet available in other languages besides English). These one-on-one in-depth interviews explored topics of experiences with the healthcare system, technology use in everyday life, and interest in using an online portal to manage healthcare tasks. We showed each participant example screenshots of the portal website during the interview.

We used both descriptive statistics and inductive, open coding to assess barriers and facilitators to portal use.

Results:
The provider/staff survey sample included 46 physicians, 18 other providers (nurse, medical assistant, etc.), and 11 staff members, with about half of respondents (45%) from community-based clinics. The mean age was 42 years, and 77% were female and 46% were white. Overall, while most stated they would recommend portal use to their patients, it was often to only a subset of their patient panel. In terms of challenges for their patients in using a portal, English proficiency (81%), literacy (75%), unreliable access to computers/Internet (71%), and unstable housing (61%) were the biggest reported perceived barriers for patients. When considering using secure messaging through the portal in their own practice, lack of time (68%) was the biggest barrier, followed by worry about patients overusing or sending irrelevant emails (47%). Specific example quotes from providers can be found in Table 1, expressing their range of feelings about incorporating portal use into their workflows in a resource-limited setting.

A total of 45 patients and caregivers were approached for individual interviews. Of those approached, 25 (59%) expressed interest in the study, 7 (16%) declined citing lack to interest in computer use, and 13 declined due to unknown or other reasons (too busy, uninterested in research). Of those who expressed initial interest, we enrolled 16 participants (55%) in the study. The patient sample included 11 patients and 5 caregivers who were existing computer users. The mean age was 55 years, 50% were African American, 63% were male, and 70% reported using the Internet daily – although the range of computer abilities/tasks was broad, with a third of participants not currently using email. (We feel that this range of computer ability matches the skill set of the broader SFHN patient population who have at least some computer experience.) The major barriers to portal use were: concerns about security of information online, lack of technical skills/interest, and preferences for in-person visits/communication. Several participants discussed fundamental barriers to using an online portal, including: challenges with reading, writing, and typing (specific quotes can be found in Table 2).

Discussion:
Providers/staff and patients/caregivers in a safety net system reported major barriers to using an online portal. Overall, there was a high level of concern about reading and understanding medical information and the security of the information online. Patients were specifically concerned about preserving existing in-person relationships with providers, and providers expressed concerns about having enough time to be able to connect with patients through secure messaging. Our findings suggest 1) a strong need for training and support to assist safety net patients with portal registration and use, perhaps most so for those with limited health literacy, and 2) considerations for changes in reimbursement or practice structures to support clinician time to be able to communicate effectively through electronic media with vulnerable patient populations.
Table 1. Provider/Staff Barriers to Portal Use

<table>
<thead>
<tr>
<th>Recommending the portal to patients</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Will recommend portal to most patients</td>
<td>I think it is important for patients to be informed of their care.</td>
<td>[The portal] will increase communication and empower patients to engage in their health care.</td>
</tr>
<tr>
<td></td>
<td>Regardless of a patient's having a computer or knowing how to use one, I think all patients have the right to know the portal exists and to try it out (if it works well...). I use Kaiser's and I find it very useful.</td>
<td></td>
</tr>
<tr>
<td>Will recommend portal to some patients only</td>
<td>I will recommend this for patients who have computer access and who will benefit from access (as opposed to getting confused and anxious).</td>
<td>For many patients this recommendation will be seen as a burden and something they are unlikely to be able to accomplish but will want to attempt in order to please the medical provider.</td>
</tr>
<tr>
<td>Unsure of whether will recommend portal to patients</td>
<td>I already have phones, jelly-beans [EHR tasks], email and mailbox to cover in answering patient needs and one more thing will drive me from primary care.</td>
<td>[I'm] not sure if it will be well used/accessed.</td>
</tr>
<tr>
<td></td>
<td>So few of our patients have access to computers and/or are comfortable working with them.</td>
<td></td>
</tr>
<tr>
<td>Won't recommend portal to patients</td>
<td>Without being able to securely contact providers to discuss results of health information this feature may not be very helpful to helping patients understand their health...I would wait until the communication piece is available before I would initiate the program.</td>
<td>For patients who do not know how to read or write in any language, such a portal will not be useful at all, further marginalizing their care.</td>
</tr>
<tr>
<td></td>
<td>[The EHR] is still full of bugs. I have little faith that this Portal will function effectively as it is housed in a poorly designed EMR system, and will only add to the confusion and tangles that our patients are confronted with.</td>
<td></td>
</tr>
</tbody>
</table>

Role of family members or caregivers in portal use

| Proxy access will be useful | I think that the adult children of some of my patients might find this useful in communicating and reaching me in a more timely manner than calling the clinic or my voicemail. I wonder how much this will help as I’ve offered my e-mail to some family members and they have declined because a majority of my patients do not know how to access e-mails or the internet. | |
| | Many of our pts would likely require the assistance of family/caregivers to use the portal due to low literacy and limited English proficiency. The extent to which this would be successful will likely depend on our ability to do outreach and education for these family members and caregivers. | |
| Concerns about proxy access | [I] worry about HIPAA. | Most [of my patients] do not have any family nor caregivers. [They are] homeless outdoors. |
| | For some this would be helpful. For others it would undermine their sense of privacy and independence. | |

Table 2. Patient Barriers to Portal Use

| Limited computer/Internet access | I go to the library sometimes or a friend’s house or something there, or when I get with the tutor or something and they're teaching me something, they'll teach me on their computer or stuff like that. | Plus, I don’t have $35.00 that happens to be the monthly fee [data for Internet on mobile phone]. |
| Fear & Experience with viruses | I’m scared of that because of viruses and stuff like that. I don’t want to. I’m a poor guy. I can’t get the computer fixed if I break it or if something infects it. | |
| Limited proficiency | I can’t type. Everything is like...I’ve got to do the two-finger thing. | That’s another thing because you got to have so many words and letter. You know, characters, so how do you distinguish that? I mean you say characters, are they letters? |
| Concerns about security and privacy | Regardless of what a person says that this site is secured and all that, I just don’t believe it....It’s not only hospitals but pharmaceutical and every researcher will tap into my information. That’s the thing that I worry about. | Hackers getting [site] everything....I had to change banks because...they had everything - my name and address - my mom's maiden name. |

Using PopMedNet to Support a Multi-Site Research Network: Lessons from PCORnet

Jessica M. Malenfant, MPH1, Jessica L. Sturtevant, MS1, Laura G. Qualls, MS2, Kyle Erickson, BS1, Lesley H. Curtis, PhD2, Jeffrey S. Brown, PhD1

1Harvard Pilgrim Health Care Institute, Boston, MA; 2Duke Clinical Research Institute, Durham, NC

Introduction: The National Patient-Centered Clinical Research Network (PCORnet) distributed research network (DRN) was established by The Patient-Centered Outcomes Research Institute (PCORI) in 2013. Phase 1 of the project included an ambitious 18 month period to implement a distributed network of networks supported by the PopMedNet™ (PMN) informatics platform. PopMedNet supports a range of health data networks, and with PCORnet, there are currently over 100 diverse sites utilizing the system across the various networks. The PCORnet implementation was the largest and most complex for any of the PopMedNet-based networks.

Methods: Implementing the PCORnet DRN involved rapidly establishing a secure PopMedNet system for PCORnet. PCORnet - designed as a “network of networks,” coupled with the large number of data partner nodes, differences in local network architecture, workflows, governance, diversity of partner informatics and software expertise, and the lack of experience with PMN and distributed analysis created numerous implementation challenges. Successful implementation was enabled through re-use of PMN components developed by previous networks, including components that had to be re-configured, enabled, or enhanced to ensure that the PCORnet could take advantage of the tools.

Based on work supported by the FDA Mini-Sentinel project, the existing PMN architecture was easily configured to meet the PCORnet usability, workflow, and governance requirements. Specifically, the methods used to associate related organizations with each other in the system coupled with integrated workflow processes related to the request and response tasks were leveraged for use in PCORnet.

Additionally, the PCORnet implementation made use of, and extended the PMN collaborative toolkit that includes collection and discovery of information about organizations and data resources. The collaborative tools used and extended by PCORnet were initially developed by the NIH Health Care Systems Research Collaboratory and FDA Mini-Sentinel project to improve the capture and use of institutional, data source, and request metadata.

Results: The PopMedNet instance for PCORnet was successfully implemented for use across the network, with over 70 unique installations representing a variety of network architecture configurations, governance, and workflow processes. Several reporting, analytic, and workflow tools supported and used by other distributed networks were also configured for use in the PCORnet. During this implementation and testing phase over 250 queries were distributes across PCORnet.

Discussion: The size and complexity of the PCORnet implementation created substantial challenges. However, the PMN infrastructure established and used by other distributed health data networks has proven to be scalable and extensible and allowed for rapid deployment for PCORnet. As PCORnet distributed research and querying activities increase and the network grows, there is an increasing need to coordinate and leverage work and resources across stakeholders and other PopMedNet networks.
Qualitative Study of an Electronic Tool for Facilitating Problem-Solving and Sensemaking in Diabetes Self-Management, Mobile Diabetes Detective

Lena Mamykina1, Ph.D., Elizabeth M. Heitkemper2, MSN, RN, Arlene M. Smaldone2, Ph.D., CPNP, CDE, Rita Kukafka1, Ph.D., Patricia G. Davidson3, DCN, RDN, Elizabeth D. Mynatt4, Ph.D., Jonathan N. Tobin5, Ph.D., Andrea Cassells5, MPH, Carrie Goodman5, MPH, George Hripcsak1, MD, MS.

1Department of Biomedical Informatics, Columbia University, 2School of Nursing, Columbia University, 3West Chester University, 4Georgia Institute of Technology, 5Clinical Directors Network

Introduction. In the United States alone, nearly 26 million adults and children have diabetes1. Self-management is a critical component of diabetes care2. Problem-solving, or one’s ability to remove barriers to engaging in self-management, is essential to successful diabetes self-management3, results in better diabetes self-care behaviors4 and leads to improvements in clinical outcomes5. There exist many innovative interventions for fostering individuals’ problem-solving skills. However, despite the high proliferation and popularity of electronic tools for diabetes self-management, few of them focus on discovery, learning, and problem-solving6,7. In this presentation, we will introduce Mobile Diabetes Detective (MoDD) – a novel electronic tool for engaging individuals with diabetes in problem-solving using data collected with self-monitoring. Using MoDD, individuals with type 2 diabetes identify blood glucose patterns that are above or below the ranges recommended by their healthcare providers, select behavioral triggers that contribute to these glycemic problems, set action-oriented goals for alternative healthy behaviors that can lead to improved glycemic control, and monitor their progress towards these goals. In this podium presentation we report the results of the qualitative study of user attitudes, preferences, and experiences with MoDD that emerged during their participation in a randomized controlled trial (RCT) of MoDD’s efficacy.

Methods. In this qualitative study, researchers conducted semi-structured interviews with individuals from economically disadvantaged communities and ethnic minorities who participate in a randomized controlled trial of MoDD, and examined MoDD usage logs. The transcripts of interviews were analyzed using inductive thematic analysis. MoDD usage logs were examined to determine usage patterns.

Results. Fifteen participants of MoDD RCT (out of 50 eligible) elected to take part in qualitative interviews. Usage log analysis showed that study participants logged into MoDD on average twice per week, reported 120 blood glucose readings during the 4 weeks of the study, and set 2 behavioral goals while in the trial. The qualitative interviews suggested that individuals used MoDD to make new discoveries about connections between different aspects of their daily activities (diet, exercise), and changes in their blood glucose levels, to experiment with new health behaviors, and to translate their discoveries into changes in self-management strategies.

Discussion. This study suggests that informatics interventions can play a proactive role in helping individuals to not only collect self-monitoring data and communicate with healthcare providers, but to also become active problem-solvers and to identify personally meaningful approaches to diabetes self-management through experimentation and discovery. In the relatively short four weeks of the study, MoDD participants were able to uncover new connections between their daily activities and changes in their blood glucose levels, experiment with new behaviors, set personally meaningful goals, and even see change in their blood glucose readings. However, the study also suggested several new directions for the design of informatics interventions for problem-solving and discovery. First, incorporating richer abilities for self-monitoring of daily activities can help applications like MoDD make tailored and personalized recommendations for problematic behaviors and suggest appropriate behavioral goals. Second, more explicit focus on barriers could help individuals to transfer their knowledge between different scenarios and situations. Finally, the study suggested the need to enrich theoretical landscape for informatics interventions for chronic disease self-management with theories that directly address the processes of discovery, experiential learning, and problem-solving.

Protein Drug Target Prioritization for Illumination
Subramani Mani MBBS PhD, Daniel Cannon MS, Tudor Oprea MD PhD, Stephen Mathias PhD, Oleg Ursu PhD, Cristian Bologa PhD
University of New Mexico Health Sciences Center, Albuquerque, NM, 87131

Developing informatics methods for protein drug target prioritization to facilitate further illumination of these targets by knockout experiments on model organisms to study their phenotypic effects will advance discovery of novel drug targets for common and rare diseases. In this study we propose an informatics approach based on machine learning for prioritizing targets from the class of proteins labeled Tdark because not much is known about them based on our current state of knowledge.

Introduction and background: Out of the twenty thousand plus proteins in the expertly curated UniProt database [1] constituting the human proteome a subset of about 1800 constitute the four protein super families—G protein coupled receptors (GPCRs), Kinases, Ion channels (ICs) and Nuclear receptors (NRs) which are of special interest from a druggability perspective. Based on the current state of knowledge of these four family targets they have been categorized into six target development levels (TDLs)—Tclin+, Tclin, Tchem, Tmacro, Tgray and Tdark. These TDLs form a spectrum with Tclin+ targets having an approved drug with a known mechanism of action while Tdark targets have minimal information (<= 1 Gene Reference Into Function (RIF), <=38 antibodies and a low PubMed text mining score.) Researchers and pharmaceutical companies have typically focused on a small part of the genome-encoded proteome for drug targeting thus shedding light on these regions from a druggability perspective while leaving large tracts of the proteome dark. Based on their review of literature Hopkins et al. report that 399 non-redundant molecular targets have been shown to bind efficaciously with small molecules [2] out of more than 10,000 likely such targets in the human genome based on projections of ligand binding domains [3]. The challenge is to identify the relevant subset of the potential druggable targets that are represented in disease-linked proteins. Note that approximately ninety percent of the currently marketed drugs interact with the various proteins encoded by the genes represented in the exome [4]. This study is part of our larger goal to develop an in-silico framework for illuminating the druggable genome (IDG) using the resources of the IDG knowledge management center (KMC) and the target central resource database (TCRD) being developed as part of the IDG effort. The TCRD contains information about human protein targets with a focus on the four protein families of GPCRs, Kinases, ICs and NRs. In this work we focus on prioritizing the Tdark targets based on their similarity with Tclin+ targets using an informatics approach to begin the process of illuminating them from a druggability potential perspective.

Methods: We extracted various types of protein descriptors that were not used in defining the TDLs. Specifically we used the Gene Ontology (GO) terms, Protein Domains (PD), Expression (tissue expression profile) and Pathway representation for these targets as attributes to identify the Tdark targets that are similar to the Tclin+ class using a novel machine learning (ML) approach based on the confusion or misclassification matrices generated by a selection of tree learning algorithms. After preprocessing we had 183 GO attributes, 113 PD attributes, 59 expression attributes and 97 pathway attributes. Using these four databases we created four lists of Tdark proteins that were similar to Tclin+. Only the list of the best performing model (Random Forest) was used to create the lists. Six pairwise intersection sets generated by independent set of predictors (databases) were used to pick the prioritized Tdark targets. Using this derived similarity measure we ranked the top Tdark targets based on their luminosity or the potential for illumination. A list based on individual databases was also generated

Results: The Tdark targets prioritized based on being similar in at least two of the matrices generated by independent sets of predictors, that is, in the intersection of the list of Tdark targets classified as Tclin+ using two different datasets is shown in Table 1. Figure 1 shows the same prioritized targets based on their representation in the specific intersection set and also the probability of being similar to Tclin+ based on our approach. Out of the nine prioritized targets the majority (6) belong to the IC family, two are Kinases and one is a GPCR.

Discussion and Conclusion: We have proposed an informatics approach based on machine learning to prioritize targets from the category of Tdark about which not much is currently known regarding their potential as drug targets. Even though ICs are a comparatively smaller family with 342 targets we could prioritize six out of the 29 Tdark ICs because 151 of the ICs were in Tclin+. On the other hand we were able to prioritize only one out of the 454 Tdark GPCRs because only 93 of the 827 GPCRs are in Tclin+. We propose to prioritize additional Tdark targets using a ML approach making use of new databases as and when they are incorporated into the TCRD. The prioritized targets will be made available to researchers performing mouse and zebra fish knock out experiments to
further illuminate these potential targets. This study opens up the possibility of drug target prioritization using informatics methods and databases to propose new drug targets from the Tdark category for further illumination.

Intra-cluster correlation estimates for design of cluster-randomized trials and multi-clinic studies that utilize electronic health record data

Miguel Marino, PhD¹, John Heintzman, MD¹, Eve Dexter, MS¹, Stuart Cowburn, MPH², Jean P. O’Malley, MPH¹, Steffani R. Bailey, PhD¹, Rachel Gold, PhD MPH¹, Jennifer E. DeVoe, MD, DPhil¹,²

¹Oregon Health and Science University, Portland, OR; ²OCHIN Inc., Portland, OR

Introduction

As the adoption of electronic health records (EHRs) in the U.S. health care system rapidly increases, EHRs could provide a robust source of relevant data for cluster-randomized trials and multi-clinic observational studies. EHR data have the potential to improve the measurement of health outcomes and confounders, and enhance the ability to perform longitudinal assessments. In studies where group randomization is at the cluster level or patients are nested within a clinic and an individual-level analysis is to be performed, the classical assumption of independence between observations do not hold because subjects within a cluster are likely to have similar characteristics/outcomes. Standard approaches to sample size equations that ignore clustering typically are underpowered. Additionally, statistical models that ignore clustering typically exhibit narrower standard error estimates. To account for the relatedness of subjects within a cluster, sample size and power formulas use a measure of dependency between the subjects in a cluster known as the intra-cluster correlation (ICC) to provide correct estimates. Efficient design of these studies requires reliable estimates of the ICC of outcomes for subjects nested within clinics to use in sample size and power calculations. This study provides ICCs estimates of common outcomes found in EHR systems.

Methods

We used data from 31 Oregon primary care clinics and community health centers that adopted the networked EHR by 1/1/2010. The clinics are members of OCHIN, Inc., a non-profit organization that provides a fully hosted instance of Epic Systems’ practice management system (PMS) and electronic health record (EHR) to safety net clinics. PMS and EHR data are managed centrally at OCHIN, including regular validation and cleaning. Data for these analyses were extracted at OCHIN. The study population includes patients aged 19-64 who had ≥1 encounter at any of the study clinics between 1/1/2010-12/31/2011. We used generalized linear mixed effects models and cluster bootstrapping to construct intra-cluster correlation estimates and effective sample sizes for a large set of healthcare outcomes commonly used in primary care research, including body mass index, vital signs, encounter counts, chronic conditions, and preventive service utilization. Estimates of ICC close to 0 denote little correlation between subjects in the same cluster driving the effective sample size closer to the total number of subjects in the EHR study sample. As the ICC approaches 1, the responses from subjects in the same cluster are close to identical. This shrinks the effective sample size towards to number of clinics in the EHR sample.

Results

Study sample included 94,961 patients served by 495 physicians in 31 clinics. ICCs varied around a median value of 0.005 (IQR:0.001-0.021). Some characteristics (such as encounters per patient) had moderate correlation within clinic (ICC=0.156; 95% CI:0.101-0.233). Among clinical outcomes shown in Figure 1, we observe that physical characteristics varied the most with the highest ICC estimated at 0.055 for diastolic blood pressure and the lowest being the proportion of obese patients at an ICC close to 0. Prevalence of chronic conditions varied much more across patients within a clinic (ICC≤0.001). Preventive service uptake also showed little correlation within clinics (ICC≤0.010). Figure 2 shows the effective sample sizes obtained from the ICC estimates for various outcomes. There is a large variation in the effective sample sizes with the highest in comorbidity outcomes and a large reduction in the effective sample size for encounter counts.

Discussion

ICC estimates in this EHR data system are small in magnitude for the outcomes examined here. However, the estimated ICCs could affect the effective sample size required for a cluster-randomized trial or multi-clinic observational studies. The ICCs presented will be useful to help plan sample size and power calculations of future studies that utilize EHR data.

Identifying Abnormal Anatomy on Temporal Bone Computed Tomography Reports Using Readily Available Natural Language Processing Software

Aaron J. Masino, PhD¹, Robert W. Grundmeier, MD¹, Jeffrey W Pennington, BS¹, E. Bryan Crenshaw III, PhD¹
¹The Children’s Hospital of Philadelphia, Philadelphia, PA, USA

Introduction

Electronic databases of health information have the potential to advance clinical research. However, significant amounts of valuable information remain locked in free text and for large databases are only accessible using natural language processing (NLP) methods. Most clinical researchers lack the expertise to use these methods on their own and must either collaborate with an established NLP expert or resort to manual chart review. Fortunately, NLP methods are increasingly packaged in well-documented toolkits, which may expand the ability of the clinical research workforce to extract useful information from free text. Audiology research represents one field of study where important anatomy information is available only in narrative reports from imaging studies such as high resolution CT scans of the temporal bones. In the AudGenDB database at The Children’s Hospital of Philadelphia there are over 15,000 unlabeled radiology reports, which represents a valuable resource for hearing loss research. Currently, researchers using this database can only use a keyword search to identify reports with specific characteristics (e.g. those that describe an abnormality). This is highly non-specific because nearly all reports mention normal and abnormal anatomical structures. Our objective was to provide a more robust search capability to identify reports with abnormalities using freely available python-based NLP and machine learning tools.

Methods

We used Python SciKit-Learn¹ and the Python Natural Language Toolkit² to dichotomously classify transcribed radiology reports as describing either normal or abnormal anatomy of ear-related structures. Any abnormality of the cochlea, cochlear nerve, vestibular aqueduct, semicircular canal, mastoid, tympanic membrane, ossicles, stapes, incus, malleus, scutum, or external auditory canal was considered a positive report. A set of 252 hand labeled CT scans of temporal bones were available for study (192 abnormal reports and 60 normal reports). Using stratified sampling we reserved 50 (20%) of the reports as a test set (38 abnormal and 12 normal reports). With the remaining 202 samples (the training set), we used 5-fold cross validation to train several models (e.g. logistic regression, support vector machines and decision trees), and select model parameters (e.g. regularization parameters) that maximized classification accuracy. Text pre-processing included word stemming and English stop word removal. Individual characters, character pairs and triples, words, and word pairs (bigramps) and triples (trigrams) were all considered as potential features. Both binary feature weighting (presence or absence of the feature) and feature counts were evaluated in model training and cross validation. Using the optimal features and parameters from the cross validation, we trained each model with all 202 training samples and evaluated performance on the 50 held-out test documents.

Results

The best performing feature sets, model parameters and predictive performance statistics on the test set are shown (Tables 1 and 2). A support vector machine with a linear kernel, regularization parameter=1.0, and character trigrams as input features achieved the best performance (recall=1.0, precision=0.95, F1 score=0.97). Naïve Bayes performed second best using character trigram occurrence as input features (recall=0.95, precision=0.95, F1 score=0.95). As a baseline, we performed a keyword search using the ear anatomy terms listed above. A document containing any of the keywords was labeled positive. The machine learning classification results are a significant improvement over the keyword search results (recall=1.0, precision=0.76, F1 score=0.86).

Discussion

Using a readily available open source NLP and machine learning toolkit and a modest number of labeled documents we were able to classify ear anatomy as normal vs. abnormal with both good recall and precision in temporal bone CT scan reports. The best-performing input features (character trigrams) and model can be constructed directly using the SciKit-Learn library. Based on these findings we conclude that researchers may be able to use basic NLP approaches readily available in open source toolkits to extract information in selected domains for their projects.

Developing InSPECt: An Interactive Surveillance Portal for Evaluating Clinical Decision Support

Allison B. McCoy, PhD1,2, Eric J. Thomas, MD3, Marie Krousel-Wood, MD, MSPH1,2, Susan C. Guerrero3, Rueben J. Applegate3, Dean F. Sittig, PhD3
1Tulane University, New Orleans, LA; 2Ochsner Health System, New Orleans, LA; 3The University of Texas Health Science Center at Houston, Houston, TX

Introduction
Healthcare providers are adopting electronic health records (EHRs) with clinical decision support (CDS) to improve patient safety and meet Meaningful Use requirements. Computerized alerts that prompt clinicians about drug-allergy, drug-drug, and drug-disease warnings or provide dosing guidance are most commonly implemented. Alert overrides can hinder improved patient outcomes, but providers are often overwhelmed with clinically insignificant alerts. Detailed evaluation of the appropriateness of alerts and clinician responses is necessary. CDS surveillance systems may facilitate evaluations and improve the appropriateness of alerts and responses.1,2

System Description
We developed InSPECt (Interactive Surveillance Portal for Evaluating Clinical Decision Support), a web-based dashboard that facilitates the review of CDS alerts and responses based on a previously implemented condition-specific dashboard that allowed clinical pharmacists and informatics personnel to review CDS alert responses in the context of patients at high risk for ADEs.3 This podium presentation will include a demonstration of InSPECt and its ability to facilitate evaluations of the appropriateness of a set of alerts or an individual alert and responses.

InSPECt was implemented using the JavaServer Faces (JSF) Java Specification and is backed by a Microsoft SQL Server database. It uses the jQuery Javascript library to enable interactivity, including the jqPlot jQuery plugin to generate graphs. Alert log and clinical data are retrieved weekly by scheduled, automated tasks that query the clinical data warehouse and transform the information to a generic data model for alert evaluation to facilitate the inclusion of alerts from additional EHRs in the future. The data model includes the alerts (unique identifier, patient, ordering provider, date/time, alert type, ordered item identifier, triggering item identifier, override flag and reason, and displayed text), triggering items, patients, and providers, where ordered and triggering items may include medications, laboratory orders or results, clinical problems, or allergies. InSPECt exists behind the institutional firewall and uses LDAP authentication with a manual approval process for allowed users. All user interactions are logged in the application database for further usability and security analyses.

InSPECt consists of two view types: the alert and the patient detail views. The alert detail view displays a graph of alert rates over time, including total and overridden alerts, along with a list of all logged alert instances. It allows reviewers to identify inappropriate alerts, showing details such as alert time; triggering medication(s), lab value, or allergy; patient demographics; and clinician name and service. The display can be filtered or sorted on any column (Figure 1). The patient detail view displays a graph of alerts and ordered medications over time, along with a detailed timeline for a patient in reverse chronological order to give context for the alerts. The timeline includes all orders, problems, lab results, and alert interactions occurring in the patient’s EHR and may be sorted on any column. Reviewers can use the patient detail view to understand clinician actions and patient condition changes occurring in conjunction with alert overrides without having to redirect to and search a patient’s EHR (Figure 2).

Conclusions
Development of an EHR-independent, interactive web-based dashboard for CDS alerts is feasible and may facilitate alert evaluations and improvements. Further research is warranted and underway to evaluate the dashboard for usability and ability to improve alert appropriateness and resulting patient safety.

Robust Sentence Segmentation for Clinical Text

Timothy A Miller, PhD, Sean Finan, Dmitriy Dligach, PhD, and Guergana Savova, PhD
Boston Children’s Hospital Informatics Program, Harvard Medical School, Boston, MA

Introduction:
Natural language processing (NLP) has been applied to clinical text for a variety of use cases, including building virtual cohorts or retrospective research.\textsuperscript{1,2,3} Machine learned models for several core NLP tasks, including detecting sentence boundaries, are part of Apache cTAKES, an open source clinical NLP tool (ctakes.apache.org). These models are designed to be portable, but in practice new domains can affect performance.

Sentences are crucial linguistic units (e.g., for extracting relations between clinical entities) and accurately finding them is important for downstream processing. Existing solutions to this task do not solve the problem in a way that addresses the diversity of clinical text. While methods from the general domain work on biological text,\textsuperscript{4} both of those domains have much more uniformity of editing and formatting than clinical text. The cTAKES system description paper\textsuperscript{5} describes excellent results on clinical text but does not report results on outside datasets. Recent work on newspaper text\textsuperscript{6} described high quality features, but ignored formatting and relies heavily on token features.

The major problem presented by clinical text is inconsistent formatting. Inconsistent use of newlines is especially problematic on the largest freely available corpus, MIMIC\textsuperscript{3}. Most segmenters ignore newlines, while cTAKES recognizes that in clinical text, a newline character often ends a sentence (in lieu of a period). However, newlines in the MIMIC corpus are highly ambiguous, sometimes inside sentences while other times ending them.

Methods:
We generalize the problem to one of character sequence tagging. Previous approaches used discriminative classifiers on a small set of candidate sentence-splitting characters. However, in clinical data a sentence break could be indicated by something as subtle as a series of spaces. Classifying the sequence of characters as the Beginning, Inside, or Outside of a sentence allows us to use similar features as previous systems while allowing arbitrary sentence boundaries. We avoid major performance penalties by only classifying non-alphanumeric characters.

We also introduce features intended to abstract away from word identity. Common words are probably valuable, so we keep some word features, but we will be unlikely to obtain a gold standard dataset large enough to capture words that are useful in all clinical sub-domains. We thus experiment with character, shape, and position features.

Character features are applied to the current character being classified as well as a window around it of n=3. These features include identity, upper or lower case, and whether it is a digit, whitespace, or punctuation. These are meant to capture patterns like punctuation around the current location (which may indicate an abbreviation), or major paragraph breaks (multiple newlines). Shape features map every character in a word to its character class and then convert it to a regular-expression-like representation. For example, capitalized words have a representation like “Ul*” to indicate an upper case character followed by a sequence of lower case characters. Shape features are applied to the two tokens surrounding the current character. Position features compare the position of a newline character being classified on a line of text to document-level line lengths. We compare the position of a newline on its line to a histogram of counts of line lengths and check whether the next word extends the line too far.

These features augment a set of widely used features from Gillick\textsuperscript{7} and OpenNLP (opennlp.apache.org): Left and right token identity, token length, right token capitalization, a log count of times the left token occurred without a period, log count of times the right token appeared lower-cased, and combined left token and right capitalization.

To evaluate these methods we manually annotated a set of MIMIC notes, including a subset of the discharge summaries, nursing notes, and radiology reports from patients numbered 1-40, consisting of 3245 sentences. We implemented the features in ClearTK (cleartk.org), a UIMA-based machine learning wrapper, using a support vector machine classifier via the LIBLINEAR library. We performed a 5-fold cross-validation to make optimal use of the relatively small dataset. We experimented with several different conditions, shown in column headers of Table 1. Performance is evaluated using precision (p), the percent of predicted spans that had exact matches in the gold standard, recall (r), the percent of gold standard spans that were found, and F1=2*p*r / (p+r).

Results:
Results are in Table 1. The cTAKES baseline performs poorly on this dataset. Gillick features in a new model trained on new data are a major improvement but still score low. Character features improve performance the most of any feature type. Shape features are less valuable on their own while position features are the least valuable on
their own. Combining all features does not improve performance over character features alone. Pairing character features with position has nominally the best result, but is essentially equivalent to character features alone.

**Discussion:**

Even with major improvement, the models trained and tested on MIMIC data do not attain performance comparable to the general domain (Gillick’s best result has an error rate of less than 1%). This may be partially addressed with more annotated data, though more diverse data sources may actually hurt performance. The sentence segmentation problem is probably inherently harder on unedited text than on edited newspaper or biomedical journal text.

The best configuration and models resulting from this work will be included as part of Apache cTAKES.

**Table 1.** “cTAKES baseline” is the off-the-shelf performance of cTAKES sentence segments, “Gillick features” is a system trained on this data with features from Gillick (2009). Columns starting with “+” indicate individual or paired feature types added to Gillick features, and “Combined features” is a system with all new feature types in addition to Gillick features.

An Analysis of Patient Portal Use in the Acute Care Setting

Eli Mlaver¹, Anuj K. Dalal, MD¹,², Harry Reyes Nieva¹,², Frank Chang, MSE¹, John Hanna¹, Sucheta Ravindran, MS¹, Kelly McNally¹, Diana Stade¹, Constance Morrison¹, David Bates, MD, MSc¹,², and Patricia Dykes, RN, PhD¹,²

¹Brigham and Women’s Hospital, Boston, MA, ²Harvard Medical School, Boston, MA

Introduction: Utilizing health information technology to engage patients in their healthcare is a growing trend, yet considerable gaps in knowledge remain regarding best practices for implementation in acute care settings.¹ Our team implemented a web-based patient-centered toolkit (PCTK), accessible on bed-side iPads, in the acute oncology ward as part of the PROSPECT (Promoting Respect and Ongoing Safety through Patient-centeredness, Engagement, Communication and Technology) project at Brigham and Women’s Hospital. The PCTK provided patients with a breadth of information related to their hospitalization. The portal’s content and design were developed using a focus group- and interview-based participatory design approach.² Given the novelty of such a program, there is still much work to be done to identify standardized techniques to gauge use of various features. The aims of this analysis were to identify consistency of and trends in patient use by length of stay in order to strengthen our understanding and guide future development of this and similar patient engagement technologies.

Methods: We reviewed PCTK activity from July 15, 2014 to January 13, 2015 using time-stamped clicks. We stratified patients into three groups based on length of stay. We excluded clicks made within an hour of the consent and enrollment period of each user to account for the tutorial we provided to users. We also calculated consistency of PCTK use as a percentage of total days used over the course of the care unit stay. We then identified changes in use of PCTK features among the short, medium, and long-stay groups. We compared continuous variables using ANOVA and categorical variables using the Chi-squared test, and we considered a p-value of less than 0.05 statistically significant.

Results: Of 137 users, 43, 51, and 43 had a length of stay of 1-4 days, 5-14 days, and 15+ days, respectively, with no significant demographic differences among the three groups (Table 1). Ninety-nine (72%) continued to use the portal after the enrollment period, and these users on average accessed the PCTK on 63% of the days they were hospitalized. We identified a total of 13,771 post-enrollment clicks based on time-stamp data, which were categorized into twelve groups (Table 2). Goals/Plan of Care, Lab Test Results, and Medications were clicked most among all groups, and all three features garnered a higher percentage of clicks among the longer-stay groups. There was a decrease in percentage of clicks in the longer-stay groups for safety information and the messaging system features—the fourth and fifth-most clicked features, respectively.

Discussion: We observed that patients who used the portal after the enrollment period had high retention of use regardless of length of stay. The data also suggest that oncology patients with longer hospitalizations seem to engage with their plan of care, test results and medication information. Further analysis with this and other patient populations should clarify whether these observations are generalizable and will the impact of other variables such as diagnosis and medication timing as well as other co-morbidities. This should provide insight into how to customize the availability of portal features by clinical unit, service, or patient. Further analysis will also look into hourly rather than daily portal use to see if patients regularly use the portal multiple times per day or at patterned times of day, which could help focus clinicians as to when to expect questions and concerns to be voiced. Insights gleaned from this analysis have directed improvement in the development of the PCTK, and we hope that it will also guide other institutions that are developing or providing similar programs.

Acknowledgements: The Brigham and Women’s Hospital PROSPECT project is part of the Libretto Consortium supported by the Gordon and Betty Moore Foundation.

Translating Electronic Clinical Quality Measures to Executable, Portable, and Customizable Workflows in KNIME

Huan Mo, MD, MS; Jennifer A. Pacheco; Richard Kiefer; Luke V. Rasmussen; Jyotishman Pathak, PhD; Joshua C. Denny, MD, MS; William K. Thompson, PhD
Vanderbilt University, Nashville, TN; Northwestern University, Chicago, IL; Mayo Clinic, Rochester, MN; NorthShore University HealthSystem, Evanston, IL

Introduction

The widespread adoption of Electronic Health Records (EHRs) has led to the development of a range of electronic clinical quality measures (eCQMs), as well as EHR-driven phenotype algorithms for clinical research. Such quality measures and phenotype algorithms are typically developed at a single site and then ported across multiple sites. To facilitate this process, it is necessary to adopt an unambiguous formal language for algorithm representation, such as the Office of the National Coordinator (ONC)-sponsored Quality Data Model (QDM). However, there is currently no widely available mechanism for translating QDM-based specifications into executable workflows that can operate on local EHR data, making the porting process difficult, time-consuming, and error-prone. As part of the Phenotype Execution Modeling Architecture (PhEMA) project, we are addressing this gap through the creation of a translator from QDM-based specifications to executable workflows for use with the open-source Konstanz Information Miner (KNIME) data analytics platform. These workflows are easily shared across multiple sites, can be connected to local repositories with varying data structures, and allow for customization to account for heterogeneous local EHR data.

Methods

The input format to our translator is the JSON representation of QDM originally developed for Project Cypress, a tool for testing eCQM validity. The translation target is KNIME, which offers a user-friendly graphical user interface with workflows represented graphically. Graph nodes represent data transformations, and graph links represent data flow (Figure 1). Our QDM2KNIME translator has three parts. First, it provides a near-complete collection of reusable KNIME nodes based on standard QDM elements and attribute sets, covering data types, temporal relationships, logical operations, and aggregative functions. Second, it provides a Java API for the stepwise construction of KNIME workflows for different translators and web applications. This includes the creation and setup of KNIME nodes, connections between them, and other necessary parts of the workflow. Third, it provides functionality for converting Cypress patient test data into a tabular format to test eCQMs inside of KNIME. We used QDM2KNIME to convert 10 published eCQMs into KNIME workflows, and tested four of them (CMS30, CMS123, CMS126, CMS179) using the converted Cypress test patient data. In addition, two of the authors (HM, JAP), tested eCQM CMS30 on EHR patient data by translation from eCQM to KNIME and execution on two different institutional repositories (VU and NU).

Results

Running the Cypress test data through the test eCQMs produced the desired results: all test patients were scored correctly with respect to each of the four selected eCQMs. This result provides us with basic validation that QDM2KNIME is generating executable workflows that faithfully represent the logic of their source specifications. A more stringent test of feasibility is to use actual EHR patient data from multiple institutions. Measure CMS30 was translated into KNIME and executed at both VU and NU. Implementation required each to configure the data access and mapping workflow nodes (Figure 1). The resulting scores broadly matched our expectations, however further evaluation against gold standard EHR data sets is planned for future work.

Discussion

We have determined the feasibility of automatically translating QDM-based eCQMs into executable KNIME workflows that can be shared across institutions and appropriately customized to handle patient data from multiple, heterogeneous EHRs. Our next steps are to integrate the QDM2KNIME translation software with the full suite of PhEMA tools, which includes a QDM-based authoring tool and the PheKB repository of phenotype algorithms. This integrated tool suite will make it possible to author and share QDM-based eCQMs and algorithms across multiple institutions with far less effort than is currently required.
Figure 1: Implementation of the eCQM CMS30 (Statin at Discharge) on KNIME. This workflow was generated automatically from a QDM-based representation of the quality measure. Nodes in the workflow graph represent data sources and outputs, data transformations implementing application logic. Connections between nodes represent data flow. After auto-generation, workflows can be modified manually using the KNIME graphical user interface.

Improving Radiology Procedure Identification for Inferior Vena Cava (IVC) Filters using EHR Text

Abstract
Insertion of inferior vena cava filters is an anticoagulation alternative in patients with venous thromboembolism. Insertions have increased without corresponding increase in retrieval despite FDA communications to remove filters as soon as possible to decrease complications. This retrospective study used VA national administrative data and found 8,314 IVC filter placements and only 980 retrievals. Placements and retrievals also occur without a standard CPT and/or ICD9 coding. We propose an alerting system to identify retained filters

Introduction
Venous thromboembolism (VTE), including deep venous thrombosis (DVT) and pulmonary embolism (PE), represents a major cause of preventable morbidity and mortality in the United States. The preferred standard initial therapy for VTE is anticoagulation; however, anticoagulation may be contraindicated or considered too risky to initiate in some. In this population, insertion of an inferior vena cava (IVC) filter has become a successful alternative. Filter placement has increased significantly over recent years, particularly since the introduction in the U.S. of retrievable filters in 2003. Filtering has been shown to offer short term protection against PE, but have been implicated in increased complication rates in the long term. A 2010 US FDA safety communication stated that retrievable IVC filters should be considered for removal as soon as protection from PE is no longer needed. Despite this, the actual rate of retrieval is surprisingly low. The aim of this study is to use a large patient database to define the cohort of patients in whom IVC filters have been placed throughout the VA system and study their outcomes.

Methodology
This is a retrospective cohort study using data available through Veteran’s Affairs Informatics and Computing Infrastructure (VINCI), which houses data from all VA medical facilities in the nation. It includes structured and unstructured data sources, administrative databases and the EHR. We identified patients with any CPT and ICD9 procedure codes related to placement or retrieval of IVC filters between 2006 and 2014. Before 2012, there were no unique standardized codes for IVC filter placement or retrieval, with multiple procedures using these non-unique codes. We searched EHR text of the cohort patients using key words to determine whether they had a filter placed or removed. Validation and improvement of the cohort is underway through keyword search and manual annotation. Once we establish the final cohort, we will report the number of retrieved IVC filters, duration of use, and complications. These methods for identifying filter procedures will be used to develop an EHR alert to track patients with retained filters.

Results
From 1/1/12 to 9/30/14, 3,553 IVC filters were placed. 698 subjects expired within 90 days of procedure. 331 filters were retrieved as determined by the CPT code for filter retrieval. Prior to 2012, 8,361 IVC filters were placed. The CPT code for retrieval used prior to 2012 was not exclusively used for IVC filters, therefore keyword search of the clinical notes in the EHR and manual chart annotation will be used to establish the number of retrieved IVC filters.

Discussion
IVC filter retrieval remains low throughout the VA medical system, despite the FDA safety communications. We anticipate finding multiple complications in the inappropriately retained IVC filter group; however, these results will be reported after establishment of the cohort. Based on preliminary work, we see a need for tracking retained filters utilizing text mining as a tool; further characterization of the latter is underway. This approach of enhancing the cohort through text searches and chart review contributes substantially to the production data more closely matching the clinical realities. This work is most significant as an example of how textual healthcare data can be incorporated into computational analysis, not solely to identify IVC retrieval but for other similar uncoded healthcare issues.

Computable Phenotypes enabled by the i2b2 Validation Platform

Shawn Murphy\(^1\), Vivian Gainer\(^1\), Victor Castro\(^1\), Alyssa Goodson\(^1\), Lori Phillips\(^1\), Sheng Yu\(^2\), Tianxi Cai\(^2\)

Massachusetts General Hospital and Partners Healthcare\(^1\), Harvard School of Public Health\(^2\), Boston, MA

Abstract: If Electronic Healthcare Record (EHR) Data is to be used for scientific discovery it must either contain parameters about its overall accuracy or we must invent methods to assess its accuracy and derive clinical meaning from it. Validation of raw EHR data accuracy often reveals poor sensitivity and positive predictive values. However, raw data consisting of codes and narrative text can be molded in most cases into accurate values. The technique for performing this transformation can be complex and requires a rigorous approach\(^1\). We wrapped a set of data transformation tools into the Informatics for Integrating Biology and the Bedside (i2b2) Phenotype Validation Platform. The platform provides both a methodology and tools and can scale to calculate large numbers of computed phenotypes and publish them back into the i2b2 database where they can be queried with the i2b2 query tool and extracted for research. Using the platform, eight computed phenotypes were created and validated in a systematic fashion. We are working to make the platform generally available for use in i2b2 and SHRINE installations.

Introduction: I2b2 is open source software that provides clinical investigators with the tools necessary to integrate and query qualitative and quantitative medical record and clinical research data\(^2\). Over 120 hospitals and academic medical centers have installed the i2b2 suite of software tools and have populated their databases with a broad range of EHR data. Unfortunately, much of the EHR data in its raw form is not useful for scientific applications because of its poor quality\(^3\). Fortunately, the existence of many types of rich data such as coded diagnoses, coded medications, and provider notes gives the scientist an opportunity to derive highly accurate data. Yet the process to derive accurate, high quality data from the raw EHR data is complex and unintuitive. Therefore, we created a platform to guide the process and perform the calculations. Methods: A workflow consisting of 6 steps was created and used to derive 8 new accurate phenotypes from the raw EHR data using tools on the Platform. In Step 1 we define the phenotype of interest, which could be as simple as a specific diagnosis but could also be more complex, such as a treatment outcome. The second step is to very loosely identify patients who may have the phenotype using easily available EHR data to allow further raw data to be collected with sufficient detail (such as narrative text) for calculations but also to allow appropriate signoffs from regulatory boards to use the detailed data for this limited set of patients. The third step is to take a sample of the patients from Step 2 and manually create a gold standard of those that have the required phenotype. The fourth step is to create a comprehensive list of features from the detailed data estimated to be useful to statistically define a phenotype. Automated tools in this step are especially useful for increasing efficiency. The fifth step is to arrange the features into a file to allow a statistical package to operate upon the features and fit the gold standard set of patients for the phenotype to the features. The sixth step is to validate the algorithm with patients outside of the gold standard training set. Results: We used the workflow of the Platform to transform eight phenotypes into new codes with high accuracy (AUC > 0.92). The phenotypes were: Bipolar Disease, Congestive Heart Failure, Coronary Artery Disease, Crohn’s Disease, Multiple Sclerosis, Rheumatoid Arthritis, Type 2 Diabetes, and Ulcerative Colitis. For each patient the new codes could now be associated with values such as sensitivity and positive predictive value from the “Confusion Matrix”. These values could then be used to query for the desired tradeoff of sensitivity/specificity when searching for patients with the desired phenotype. Discussion: The limitations of raw data from the EHR can disrupt approaches to scientific discovery using this data. We have been developing systematic approaches to curating this data to provide new derived codes of greater accuracy for phenotypes of interest. The tradeoff is that the process is complex and time-consuming for deriving these codes. To make these techniques more available to mainstream computing, we have encapsulated them into a platform that make the process easier to manage.
Figure 1: Eight new highly accurate codes for phenotypes were created from the platform described and integrated into i2b2 so that they could be queries and used for further analysis along with other data in the database.

Will they participate? Predicting patients’ response to clinical trial invitations

Yizhao Ni, PhD1, Andrew F. Beck, MD, MPH1, Regina Taylor, MA1, Jenna Dyas, BS1, Imre Solti, PhD, MD, MA, MSc1, Judith W Dexheimer, PhD1

1Cincinnati Children’s Hospital Medical Center (CCHMC), Cincinnati, OH

Introduction

Challenges with patient recruitment for clinical trials are recognized as a major barrier to the timely and efficacious conduct of translational research. Studies have identified various patient- and physician-level factors that impact the successful recruitment of patients for clinical trials1,2. This work has focused on factors impacting patients’ enthusiasm for contributing to a trial, including acuity of their clinical problems, demographics and socioeconomic status (SES), and trial characteristics2,3. To take the next step, our objective is to develop a machine-learning model to predict a patient’s response (i.e., if the patient agrees or declines) before he/she is approached for a clinical trial.

Data and Method

We focused on clinical trials for pediatric patients who visited the Emergency Department (ED) at Cincinnati Children’s Hospital Medical Center (CCHMC) between 1/1/2010 and 8/31/2012. All 18 ED clinical trials that required patients’ consent before enrollment were included in the study. During the study period patients in 3134 encounters were eligible for one of the trials and were approached for consent. Patients in 1911 encounters agreed to participate in the trials (consent rate 61%). Based on the literature, we retrospectively collected a list of variables from multiple sources (Table 1), including the patients’ visit data (e.g. demographics and acuity of clinical problems), a proxy of SES, and the characteristics of the clinical trials. To estimate their SES, the patients’ addresses were geocoded to identify the census tract in which they lived. Ten socioeconomic characteristics from the 2008-2012 US Census American Community Survey were then extracted as proxies for individual-level SES (Table 1).

Patients’ responses from the 3134 encounters served as a set of gold standard to train and evaluate the predictive models. We performed a stratified random sampling based on numbers of patients approached for each trial to split the data into two sets, 90% for training and development and 10% for evaluation. The baseline is a random response predictor using the binomial probability model, where the probabilities of agreeing/declining a trial invitation were optimized by maximum likelihood estimation. We then compared the baseline with logistic regression (LR), where ten-fold cross-validation was used to optimize the cost parameter (C) screened from 2^-20 to 2^20. The nominal variables (e.g. gender and insurance type) were converted to binary features, while the numerical variables (e.g. SES data) were discretized into ordinal features using the Chi-square test. Macro-average positive predictive value (PPV), recall (R), negative predictive value (NPV), specificity (SPC) and the area under the ROC curve (AUC) were calculated to assess the algorithm performance. In addition, we tested the three variable sets (visit data, SES data and trial characteristics) individually and in combination to validate their respective contribution to the predictive model.

Results and Discussion

The performances of the baseline and the LR algorithm are presented in Table 2. Compared with the baseline, the LR algorithm achieved better AUC. The LR with all variables achieved the best AUC (set 7). Improvements were statistically significant over the LR s using individual sets, and the combination of visit and SES data (set 1-4). Among the variable sets, the trial characteristics (set 3) were shown to be more informative than the others. The visit data was less informative, but combining it with the trial characteristics (set 5) significantly improved the AUC (p=1.4E-2 under paired t-test). Including SES data barely improved the performance, possibly due to the fact that the data is ecological, referring to the status of the geographic areas and not specific to individual households. Table 3 shows the features from the multivariable LR model that were associated with patients’ response at p=0.1 significance level. We observed that patients were more likely to participate in disease-specific and interventional studies. They were less likely to participate in multi-center trials, more invasive trials, and trials that required follow-up visits or phone calls. Multiple factors on patients’ visits were significantly associated with their response to a trial invitation, including the seasons of their visits, their arrival means, length of stay and disposition. Finally, some of the patients’ characteristics, such as race and SES, could also influence their enrollment preference.

The developed algorithm and the observations could have potential for significant impact in the strategic planning of clinical trial enrollment. The algorithm could facilitate recommendations of trials to patients in ways that maximize chance of enrollment. We could also recommend the patient to a trial that has higher priority in strategic planning and with an acceptable level of enrollment possibility.

Comparing Weight Redistribution and Distance Imputation Methods for Missing Data in Clear-text and Encrypted Record Linkage
Toan C. Ong, PhD1, Lisa M. Schilling, MD, MSPH2, Michael G. Kahn, MD, PhD1
Departments of Pediatrics1 and Medicine2, School of Medicine
University of Colorado Denver, Colorado USA

Introduction
Complete data are necessary to perform high-quality comparative effectiveness and outcomes research. Complete datasets can be created without sharing clear-text identifiers by performing privacy-preserving record linkage (PPRL) on distributed datasets that capture data from different sources (e.g. clinical, claims) for overlapping patients. [1-4] PPRL is usually performed by comparing one or multiple common encrypted linkage variables, also called quasi-identifiers.[5] Probabilistic record linkage methods assigns a weight to each linkage variable, which captures the ability of that variable to discriminate correct from incorrect linkages.[6] The incorporation of distance measurements, such as dice coefficient, allows PPRL methods to be tolerant of data incorrectness.[7] A similarity score representing the similarity between two records is computed based on the weight and distance between linkage variables. A match is determined by comparing the similarity score to a threshold, called the acceptance level. Despite being able to deal with incorrect data, current clear-text and encrypted record linkage methods usually do not have a robust mechanism to deal with missing linkage data. For example, the open-source FRIL system offers the FRIL-0 option that assigns zero distance to linkage variables with missing data, which essentially declares all missing variables to be non-matching.[8] In a recent publication, we demonstrated the superior performance of two novel methods, Weight Redistribution (WR) and Distance Imputation (DI), to solve the problem of missing linkage data in clear-text record linkage.[9] We applied the same methods to both clear-text and encrypted data and compare their performances with the FRIL-0 method. Since encrypted data require different methods to measure the distance between two values, the effectiveness of the previous methods is not guaranteed.

Methods
Four datasets, which were divided into 2 groups, were used to test the WR and DI methods. Group 1 contained 2 datasets with clear-text data and group 2 contained 2 datasets with encrypted data. Each dataset contained 5000 records and pairs were designed to have exactly 3000 match records. The clear-text data were corrupted to simulate typographical errors (e.g. letter deletion, insertion, and transposition) and values were randomly removed entirely to simulate missingness. The average corruption rate and missing rate in each field was approximately 10%. To ensure comparability, the corrupted clear-text data were used to create the encrypted dataset using two encryption steps: 1) hashing clear-text value with a single 256 character random string salt and 2) adding hash values to a Bloom filter. [10] The linkage fields used for all methods include first name, last name, birthdate, sex, and city of birth. Sex was not used as a linkage variable in our previous publication. Refer to http://goo.gl/ODgMZb for more detailed information about the WR and DI methods and examples with clear-text data.

Results
We compare the performance of three methods with different acceptance levels to deal with missing linkage data in both clear-text linkage and PPRL (Table 1). WR and DI had a much higher overall number of true positive (TP) than did FRIL-0. All methods have positive predicted values (PPV) greater than 0.96 but they have marked differences in sensitivity with both WR and DI having greater sensitivity than FRIL-0. Using the methods on encrypted data sets, derived from the clear-text data sets, did not decrease the sensitivity of the methods. With both clear-text and encrypted data, raising the acceptance threshold eliminated the false positives (FP) but also decreased the sensitivity of the match, resulting in more false negatives. For each dataset type with equal acceptance thresholds, DI appears to have the highest number of TP matches and fewest FP cases.

Discussion
The results showed that the WR and DI methods, which have mechanisms to deal with missing linkage data, outperformed the FRIL-0 method in all performance measures. However, in some cases both of these methods produced FP matches, which would incorrectly merge records from two different individuals. With clear-text data, although the WR method with acceptance level = 80 (row #2) produced 3 FP matches, it was the most effective method with the highest number of TP matches and low FP matches. In addition to increasing the acceptance level to limit the number of FP cases, another solution could be to use more discriminating fields as linkage variables. With encrypted data, including more discriminating linkage variables will also reduce the number of FP cases. The results showed that WR and DI also provide a promising solution for missing linkage data in PPRL.

### Table 1 – Performance of record linkage methods

#### References

#### Abstract

Missing data in record linkage variables can negatively impact the effectiveness of privacy protected record linkage (PPRL). Weight Redistribution and Distance Imputation are novel methods developed to deal with missing data in record linkage variables. Using synthetic datasets with corrupted and missing data we showed that the performance of clear-text and encrypted probabilistic record linkage was improved and not markedly different with encrypted variables. These methods provide promising solutions to missing linkage data in PPRL.
Quantifying Tobacco Exposure Using Clinical Notes and Natural Language Processing to Enable Lung Cancer Screening

Travis J. Osterman DO1, Wei-Qi Wei MMed, PhD1, Joshua C. Denny MD, MS1
1Vanderbilt University, Nashville, TN

Introduction
Lung cancer is the leading cause of cancer-related mortality worldwide with 1.2 million deaths annually1. The National Lung Cancer Screening Trial demonstrated a reduction in lung cancer-associated mortality through annual screening of high risk patients2,3. Based in part on those results, the United States Preventative Services Task Force (USPSTF) recommends annual screening for patients age 55-80 that have 30 or more pack-years (PY) of tobacco use4. Previous research has focused on identifying smokers from EHR data. Here we propose an algorithm to calculate lifetime tobacco exposure in PY using unstructured narrative text from the social history (SHx) section of clinical notes.

Methods
This study used Vanderbilt University Medical Center’s de-identified electronic health record (EHR) with institutional review board approval (IRB #142018). A training set of 250 individuals with a history of smoking was identified from the EHR using a previously validated algorithm5. A validation set of 1000 individuals was selected randomly from the EHR. The SHx from each encounter is stored in the EHR as unstructured free text. The most common, non-blank, social history for each patient was considered the SHx for this study. Sixteen individuals with no available SHx were removed from prior to analysis.

Each individual’s SHx was manually reviewed by two physicians to quantify tobacco usage in PY. This served as the ground truth. We implemented a tiered, rule-based, system using regular expressions (RE). The first rules determine whether the sentence discusses smoking. The second set of rules determines whether PY calculation is possible. A third set of rules extracts rate, duration, and/or total PY. Finally, a PY duration is calculated.

Precision, recall, and F-measure are reported for the second set of rules which identified text with adequate data for extraction (ie: rate and duration, or PY). Tobacco exposure in PY was analyzed using Pearson correlation and root mean square error (RMSE). A one-tailed exact binomial test (α = 0.05) was used to analyze individuals meeting USPSTF screening criteria as previously described and reported using a p-value.

Results
A total of 984 individuals’ SHxs were used for validation (Table 1). There were 162 (16%) smokers in this group. Fifty-three (5.4%) individuals had sufficient information to calculate PY. Mean PY was 31.5 with a range [0.43 – 104]. Nineteen individuals qualify based on USPSTF age and PY criteria. Forty-six of 53 SHxs were correctly classified as having sufficient data to calculate PY (1 false positive, 7 false negatives, precision: 0.98, recall: 0.87, and F-measure: 0.92).

The model made PY predictions on 47 individuals with a Pearson correlation of 0.78, 95% confidence interval [0.65 – 0.87], (Figure 1) and RMSE of 8.1. Fourteen of 19 individuals were successfully identified as lung cancer screening candidates (exact binominal test p-value 0.03).

Discussion
We developed an algorithm to quantify tobacco exposure in PY and report a strong correlation between our prediction and physician review. Using this tool, we were able to identify individuals who qualify for USPSTF lung cancer screening. However, several challenges arose while working with these data. First, these rules are based on a loose vocabulary that includes non-standard abbreviations and misspellings which may be medical center or regionally dependent. Also, our algorithm did not consider when former smokers had quit smoking. Finally, we did not parse the entire clinical note for smoking information outside of the SHx

Conclusion
We have shown the problem of quantifying tobacco exposure can be addressed with common informatics tools. This model can be used to identify potential candidates for lung cancer screening at other medical centers.

Title: Patient Access to Electronic Health Records During Hospitalization: High Expectations, Fewer Problems, and Fewer Benefits Than Expected

Introduction- In 2001, the Institute of Medicine recommended improving patient engagement by providing care that is continuous, allowing patients to be the source of control, and fostering transparency with patients and families¹. Electronic health records (EHRs) facilitate these objectives via the use of patient portals. Giving outpatients direct access to their health information helps clinicians find errors and improves patient satisfaction, although the implications of this type of access has not been well studied in the inpatient setting². This hospital-based study evaluates the patient, clinician, and nurse experience with immediate (real-time) release of test results and other EHR information through a patient portal.

Methods- This prospective cohort study was performed on a medical unit at a 412-bed, academic tertiary care hospital, from October 2012 to March 2013. Participants were hospital clinicians, nurses, and patients. Patient participants were enrolled by convenience sampling and used a study-provided electronic tablet to access parts of their EHR, including medication schedule, and test results. Patients, clinicians, and nurses completed a survey before and after the intervention. The survey evaluated the domains of caregiver workload, patient confusion and worry, patient empowerment, error finding, and discharge planning. McNemar’s test was performed to analyze binary data between paired responses on surveys for all groups.

Results- Response rates for individuals completing both pre- and post-intervention surveys were 100% for patients (n=50/50), 93.3% for clinicians (n=28/30), and 87.5% for nurses (n=14/16). Patient portal use (defined as clicks/day) was 15.6 (SD=16.2; median=11.2; range=0.26-86.8), and time logged on ranged from 2-1331 minutes. We did not assess the use of the tablet for other purposes or by other users. Figure 1 shows the pre- and post-intervention survey results. The majority (≥65%) of clinicians and nurses were concerned that giving patients immediate access to their test results would increase their workload, but this sentiment decreased in both groups post-intervention. Concerns that seeing test results would cause patient worry were high (>85%) among clinicians and nurses and greater than among patients pre-intervention, but these concerns decreased in all groups. A majority of patients endorsed empowerment items including control, understanding, reassurance, following recommendations, and trust both pre- and post-intervention.
Clinicians (96%) and nurses (93%) were more optimistic than patients (44%) that patient access to their medication lists would help them find errors, and this decreased significantly across all groups post-intervention (patients, -38%; clinicians, -31%; nurses, -43%). Prior to the intervention, most patients (67%) indicated that they would better understand when they would be discharged, but after the intervention, the number of patients endorsing this item fell significantly (-42%, P<.001).

**Discussion** - The suspected risks of giving inpatients direct access to their EHR did not bear out with no increase in workload reported by nurses or clinicians and no increase in confusion or worry reported by patients. Consistent with outpatient studies, patients answered more positively to empowerment questions after being given EHR access. Despite supporting patient empowerment, the promise of patients finding errors in their medications or knowing when they were being discharged never materialized. This is the first published study we are aware of that has evaluated the experience of a large sample of inpatients and their front-line care providers with real-time inpatient EHR access, although it involved patients and providers on a single hospital unit. Federal programs recommend that patients be able to access results from their hospitalization within 36 hours of discharge. This requirement still misses an opportunity for patient engagement through better transparency, and future policies should consider real-time EHR access for inpatients.

Uncovering the Cognitive Demands of EHR Use via Task Analysis

Mark S. Pfaff, PhD1, Ozgur Eris, PhD1, Amanda Anganes, MS1, Mohammad Rahman, MA1, Tina Crotty, MA1, Jonathan Nebeker, MS MD2, Merry Ward, PhD3

1The MITRE Corporation, Bedford, MA. 2Salt Lake City VA Medical Center, Salt Lake City, UT. 3Department of Veterans Affairs Office of Informatics and Analytics, Raleigh, NC.

Introduction

Using an electronic health record (EHR) system places many cognitive demands upon the user. Complicating an analysis of these demands is the heterogeneity of the many user roles and the vast scope of system functionality. Expert clinicians are highly adaptive to the constraints of the EHR as they develop strategies to seek, share, and store information.1 In this study, 10 clinical experts in a variety of clinical roles were interviewed to elicit the types of challenges that EHR users face and the cues and strategies they employ to overcome those challenges.

Methods

Applied Cognitive Task Analysis (ACTA) was chosen as the method based on its structured approach for eliciting cognitive demands and skills from expert decision makers.2 In particular, ACTA captures expertise in a way that facilitates its transfer to trainees and translation into design recommendations for interactive systems. Interviewees included both inpatient and outpatient practitioners using a variety of EHR platforms: four primary care physicians, two nurse practitioners, one registered nurse, one physician’s assistant, one clinical pharmacist, and one patient care coordinator. The average years of clinical experience was 23.9 (range 8-35). Each interview was jointly conducted by two researchers and lasted approximately two hours.

Results

Using a grounded approach, several themes emerged from the interviews, as presented in Table 1. The reported issues refer to specific EHR implementations and are not necessarily global issues with all EHRs. Nine of out the ten participants reported that they rely 100% on their EHR to perform their clinical tasks. The exception was an ER nurse using a 14 year-old system that served as more of a distraction from other duties than an aid in her work.

Discussion

Fragmentation of information either within or between systems was the top complaint from participants. Requiring users to seek and integrate information from multiple sources requires slow effortful thinking and extensive knowledge of how to navigate the system, whereas displays that present all necessary information in one place would enable rapid associative thinking.3 “What if?” tools were frequently noted as a desired feature, indicating limited support for planning in current EHRs. Ordering medications was a recurrent point of pain for many of the participants. This problem represented the intersection of information overload (vast lists of available medications) with the heightened possibility of entry error (e.g. selecting one above or one below the desired medication) and the needle-in-a-haystack search for a medication that turns out not to be in the system at all.

Communication was also a common sticking point. It is generally hard to know whether someone has received or read important information about the patient – one must rely on trust that other members of the team know what they need to know or have completed expected tasks. This reflects problems in establishing common ground4 and ensuring the team understands the current care goals and the knowledge and responsibilities held by team members.

This research aimed to understand the cognitive demands from a variety of clinicians’ EHR use in different clinical environments and roles. Some of the previously identified cognitive consideration categories for EHR design, such as support for an accurate situation model of the patient, common ground, and planning and action, were encountered and detailed. Ongoing data analysis will further substantiate and structure those dimensions.

This work was funded by the Department of Veterans Affairs (VA) Office of Informatics and Analytics/Health Informatics/Vista Evolution (Projects VA118A-13-D-0037 and VA118A-14-J-0194). Approved for Public Release; case #15-0601.
Table 1. Selected cognitive demands of using an EHR extracted from the ACTA interviews

<table>
<thead>
<tr>
<th>Cognitively demanding issue</th>
<th>Why is it difficult?</th>
<th>Expert strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patient information is scattered throughout the same EHR system.</td>
<td>Fragmentation within the EHR results in clinicians engaging in “detective work” in order to construct a holistic and accurate picture of a given patient. This can cause critical pieces of information to be unavailable during care. For instance, lab results associated with an initial acute encounter are not linked to the chronic condition which consequently develops.</td>
<td>Develop an accurate mental model of the topography of the EHR coupled with a sophisticated understanding of the scenarios that invoke the use of its different parts and modules. Clinicians repeatedly stated that “knowing where to look” within the EHR is required to find connections among data.</td>
</tr>
<tr>
<td>The EHR module is not matched to the clinical task, and it functions with inaccurate risk/benefit assumptions.</td>
<td>“One size fits all or provides the most coverage” approach to EHR application can cause a significant mismatch between the clinicians’ needs and the EHR’s functionality. For instance, this can happen when a nurse is forced to fill in several screens in order to be able to order blood while a patient bleeds out during surgery in the OR. The criticality of the information might be justified in a less risky operational environment, but is unjustified in an emergency situation in the OR.</td>
<td>Employ informal communication or task execution mechanisms that do not involve the EHR. Bypass the EHR to the best extent possible. In the OR case, the nurse uses the phone to place the order although she is still required to follow up with the EHR to place the official order (still poor use of critical OR time).</td>
</tr>
<tr>
<td>Effortless generation of effortful downstream work through EHR’s automation capability.</td>
<td>Clinicians operating upstream in the clinical workflow have the ability to create generic care order templates that are specific to a condition, and automatically apply them to multiple patients sharing similar conditions with very little effort. However, not every single order on a template is relevant to a given patient, which results in information overload and time pressure in a pharmacy or laboratory.</td>
<td>If operating downstream in the clinical workflow, take control of existing order templates and the process of creating new templates (e.g. administratively limit clinicians’ ability to overuse automation).</td>
</tr>
<tr>
<td>Asynchronous electronic communication capability of EHRs</td>
<td>Clinicians can send messages to each other through the EHR, but it is difficult for a clinician to read and respond to each message in the presence of other more pressing responsibilities. This results in communication overload.</td>
<td>Try to identify and only respond to important EHR messages, ignore the rest, and revert to informal synchronous communication mechanisms such as the telephone to execute high-priority tasks.</td>
</tr>
<tr>
<td>Medication ordering presents overwhelming choices</td>
<td>In the interest of being comprehensive, pull-down medication lists include many variations of a drug, making selection a possible source of data-entry error.</td>
<td>Develop custom lists of “favorite” or frequently ordered medications.</td>
</tr>

Status of the Health Center-Controlled Network Program: Advancing Health Care Quality through Health Information Technology at Community Health Centers

Anna Poker, RN, MS; Derrick Wyatt, RN, MS; Dominick Black; Suma Nair, MS, RD; Beth Perrine, MA; Tracey Orloff, MA

Author affiliations: AP, DW, DB, SN, BP and TO – Health Resources and Services Administration, Rockville, Maryland

Introduction and Background:

Health Center-Controlled Networks (HCCNs) are consortia of community health centers (HCs) funded by the Health Resources and Services Administration (HRSA), an agency within the U.S. Department of Health and Human Services. In FY2013 HRSA funded a total of 43 HCCNs to advance health care quality through health information technology (health IT). This 3 year HCCN program totals $21 million/year has three main goals: 1) to advance the adoption of ONC certified electronic health records (EHRs,) 2) to promote the participation of eligible providers (EPs) in the EHR incentive program from the Centers for Medicare & Medicaid Services commonly known as “Meaningful Use,” and 3) to improve quality through achieving Healthy People 2020 goals and through recognition of HCs as Patient-Centered Medical Homes (PCMHs).

Methods: We analyzed grant grantee application information to collect baseline data for all the projects. We compiled descriptive data about the number of HCs and the number of EPs across the HCCN program. The baseline data about each HCCN grant project, including the percentage of EPs participating in Meaningful Use, the percentage of HCs that have achieved the Healthy People 2020 goal on at least one measure reported in the Uniform Data System (UDS)¹, and the percentage of HCs that have received PCMH recognition is compared with yearly progress reports.

Results: The HCCN grant program consists of 43 network grantees, which corresponds to 768 HRSA-funded HCs, 3,554 clinical sites, 13,928 clinical providers, and over 12 million patients served. Data collected from Year1 of the Progress Reports reveal that the mean percentage of clinical sites that have adopted EHRs is 90.2 % (from 82%). The mean percentage of EPs who have registered and attested/applied for Meaningful Use payments is 76% (from 66%), while the mean percentage of EPs who have received Meaningful Use payments is 69% (from 56%). The mean percentage of HCs that have achieved the Healthy People 2020 goal on at least one UDS clinical quality measure is 90% (from 75%). The mean percentage of HCs that have achieved PCMH recognition is 42% (from 17%).

Discussion and Conclusion: The HCCN grant program has substantial reach and shows advancements in propelling health centers toward improved quality of health care delivery for millions of underserved and medically vulnerable people served by HRSA-funded HCs. Although HCs are advanced in terms of health IT adoption there is great opportunity for them to optimally use their EHRs and health IT. The HCCNs are providing support for HCs to capture, analyze, and return actionable data for quality improvement at the HC level and to improve population management endeavors.

¹ The Uniform Data System (UDS) is a core set of information appropriate for reviewing the operation and performance of health centers. Health centers report UDS data to HRSA annually.
Interim Results of a Randomized Controlled Trial on Inpatient Engagement

1Dept. of Biomedical Informatics, 2Dept. of Biostatistics, 3School of Nursing, 4Dept. of Medicine, 5Dept. of Computer Science, Columbia University, New York, NY; 6NewYork-Presbyterian Hospital, New York, NY

Introduction

The impact of patient engagement has been likened to that of a “blockbuster drug.” Higher levels of patient engagement may improve patient satisfaction, patient–provider communication, and adherence to treatment plans. While patient engagement has been a focal point in the outpatient setting, little work on this topic has been conducted within the hospital. This podium presentation will report interim results of a randomized controlled trial (RCT) that evaluates the impact of a tablet-based patient portal tool in the hospital setting.

Methods

Beginning in summer 2014, patients on cardiology wards at Columbia University Medical Center were enrolled in a three-arm RCT, receiving either: 1) usual care, 2) a tablet computer with basic access to the internet, or 3) a tablet computer with access to a personalized patient portal, Inpatient myNYP. Patients responded to a survey consisting of satisfaction and usefulness items, and care team member awareness, along with the Patient Activation Measure (PAM). The PAM classifies individuals into four hierarchical levels, from Level 1 (“Disengaged and overwhelmed”) up to Level 4 (“Maintaining behaviors and pushing further”). Five-point Likert-type scales were used to assess patients’ agreement with survey items (1=“Strongly Disagree” to 5=“Strongly Agree”). Descriptive statistics were calculated for Likert-type survey questions. A within-subjects ANOVA model was used to analyze differences of patients’ perceived ability to identify their care team members. Analyses were performed using R.

Results

Through February 2015, 45 patients have been recruited into the RCT (Table 1). The majority of the participants are male (73.3%), and White (57.8%), with an average age of 63.9 (SD=13.6). At baseline, most participants (51.1%) scored in the third level of the PAM. The distribution of key Likert-type survey question responses can be seen in Figure 1. Results were mostly positive (“Agree” to “Strongly Agree”) to questions about hospital care and care team satisfaction. Figure 2 shows the responses of the perceived knowledge of care team member types. The ANOVA model for the three questions in Figure 2 found an estimated mean score of 4.11, 3.61 and 3.27, respectively (p-value <0.0001, with all three pairwise comparisons also statistically significant), indicating patients were most likely to know the identity of their nurses, followed by their physicians, followed by allied care providers.

Discussion

The positive trend of responses to the survey questions suggests that study participants were generally satisfied with their care in the hospital and believed their care team members listen and encouraged them to participate in their care. However, over 25% of patients chose “Strongly Disagree” or “Disagree” in response to, “I am more involved in my healthcare than I was before my hospital stay.” This result underscores the importance of education and communication during the hospital stay. Knowledge transfer and engagement during this critical period can help patients regain their sense of control before they are discharged home. The results of the ANOVA model, which showed that patients were better able to identify their nurses than their physicians and allied health providers, can be interpreted in at least two ways. First, nurses typically provide more direct patient care than other team members, and thus may establish a more memorable relationship with their patients. Second, in the clinical environment where the study was conducted, nursing practice included manually updating a whiteboard with the name of each patient’s current nurse. Overall, patients seemed to lack familiarity with non-nurse care team members. Improving patient knowledge about the identity of care team members could increase patients’ feelings of control over their care.

What causes pneumonia? Kinds of Knowledge and the Case for Hybrid Representations

Alan L Rector, MD PhD
University of Manchester, Manchester, UK

Introduction

Why is interoperability so difficult? Why have stable standards for EHRs, terminologies, and clinical decision support proved so elusive? One reason is the failure to distinguish fully between different kinds of knowledge and attempts to extend tools built for one kind of knowledge to use for others for which they are inappropriate.

Methods

The paper uses a seemingly simple example of just three families of knowledge representation and data schema formalisms – 1) logic based – SNOMED & OWL – 2) frames, and 3) UML. However, much of what is said applies to RDF, Archetypes, HL7 CDA etc. The result is a set of requirements for hybrid systems and the interfaces among their components. We explore both theoretical issues in the distinctions and the practical technical issues, focusing on the relationship between open-world axiom-oriented representations – e.g. SNOMED’s description logic and OWL – and closed-world template-based representations – e.g. UML Archetypes, frames, etc. The classification of types of knowledge and their relationship to common formalisms is shown in Tables 1 & 2.

No one representation covers everything, even if we limit ourselves to deterministic symbolic representations. For example, OWL/DLs support composite terms, logical definition and classification but not generalizations. Frames, by contrast, support generalizations, but not composite terms, definitions, or classification. UML interfaces more naturally to frames but, in principle at least, specifies data structures rather than knowledge per se.

“Stretching” any one technology to forms of knowledge for which it was not designed causes problems. In particular, attempts to derive UML schemas from OWL or transform OWL to frames usually founder on their different semantics – open-world axiom-based for OWL vs. closed world template-based for frames and UML. These issues can be mitigated, but only by using nonstandard and non-obvious patterns and transformations¹.

Particular problems arise in understanding the difference between OWL/DL expressions and queries on OWL/DL ontologies – e.g. using the new SPARQL 1.1 OWL entailment regime² or the SNOMED Expression Constraint Specification³. Many interfaces between ontologies and other representations depend critically on such queries – for example, “find all of the subcategories of hypertension not classified under diseases of pregnancy”⁴ is very different from the similar DL expression “Find all subclasses of hypertension that necessarily exclude pregnancy.”⁵⁶

Results

The requirements for a representation environment include support for domain knowledge, information schemas, and data. All three forms of domain knowledge are needed – ontologies, generalizations, and specifics. Most practical development also requires language tools to capture what people actually say and avoid misunderstandings – for example even though “subdural hematomas” can be extracranial, if unqualified, “subdural hematoma” almost always indicates intracranial pathology.

There are fundamental logical issues in combining the axiom-based open-world reasoning needed for ontologies/terminologies with the closed-world representation needed to represent generalizations and used by the most rule environments. Hybrid systems are required. For standards development the interfaces among the various parts of the hybrid representation need to be principled and declarative although in places they will necessarily be heuristic to cope with computationally intractable issues. For example, the ICD 11 linkage between the Ontology and Foundation Component⁴ illustrates an interface between ontologies and other representations using queries. In programming environments, more algorithmic approaches such as Hobo⁵ may be appropriate. There are even more serious theoretical issues in incorporating more radically different representations such as Bayesian Networks.

In short: no one representation is sufficient. OWL is not enough; frames are not enough; UML is not enough. It is time for better hybrid solutions.

Understanding Challenges and Opportunities in Precision Medicine and Interoperability Using Informatics Approaches

Jay Geronimo Ronquillo, MD, MPH, MMSc\textsuperscript{1,2}, Chunhua Weng, PhD\textsuperscript{3}, William T. Lester, MD, MS\textsuperscript{4,5}

\textsuperscript{1}Office of the National Coordinator for Health Information Technology, Washington, DC; \textsuperscript{2}Grinformatics, Haymarket, VA; \textsuperscript{3}Columbia University, New York, NY; \textsuperscript{4}Harvard Medical School, Boston, MA; \textsuperscript{5}Massachusetts General Hospital, Boston, MA

Introduction

The Office of the National Coordinator for Health Information Technology (ONC) promotes initiatives that establish and implement standards for certified health information technology (IT) capable of effectively exchanging diverse health data\textsuperscript{1}. Precision medicine is broadly defined as the application of patient-specific genomic information for highly targeted and effective methods of clinical diagnosis, management, and treatment\textsuperscript{2}. Precision medicine has the potential to leverage health IT in ways that could dramatically improve public and population health, bringing practical genetic information exchange into sharp focus\textsuperscript{3}. We can gain insight into the challenges and opportunities intersecting precision medicine and interoperability by analyzing population-level genetic test data, public nomenclature databases, and accepted standards for exchanging genomic information. The purpose of this study was to 1) build an informatics pipeline capable of integrating diverse datasets describing genetic test information, and 2) gain insight into the current state of precision medicine as it relates to data standardization and exchange.

Methods

The NIH Genetic Testing Registry (GTR) provides a comprehensive description of registered genetic tests offered by various laboratories and organizations for clinical applications\textsuperscript{4}. As a starting point for assessing health IT conformance to standards for encoding genetic test data, we chose the HL7 Version 3 Implementation Guide for Family History Interoperability. The minimal core dataset in this implementation guide requires descriptions from both the Human Genome Organization (HUGO) Gene Nomenclature Committee (HGNC) database as well as the National Center for Biotechnology Information (NCBI). We created an informatics data pipeline in python that identified all clinical genetic test information from the NIH GTR, mapped genetic test data to standard identifiers in the HGNC database and NCBI, and created an integrated dataset for analysis\textsuperscript{5}. Analysis was performed using open source statistical software PSPP version 0.8.4 and Microsoft Excel version 14.2.0 (Redmond, WA).

Results

There were a total of 25472 genetic tests submitted by 240 different organizations to the NIH Genetic Testing Registry, testing for approximately 3632 distinct genes. Of these tests, 23999 (94.2\%) were submitted specifically to the NIH GTR, while 1473 (6.1\%) carried over from the earlier GeneTests Laboratory Directory. Of the tests in the NIH Genetic Testing Registry, 23829 (99.3\%) were focused on germline mutations, 113 (0.5\%) on somatic mutations, and 57 (0.2\%) did not provide this information. All 3632 genes were matched to an approved symbol and identifier from HGNC, and 3594 (99.0\%) of these genes were successfully mapped to NCBI RefSeq identifiers. There were a total of 5319 conditions associated with these tests, with 1136 (21.4\%) currently assigned a SNOMED-CT code. The reported purposes for each genetic test were as follows: 23274 (97.0\%) diagnosis, 147 (0.6\%) drug response, 384 (1.6\%) monitoring, 11119 (46.3\%) mutation confirmation, 151 (0.6\%) pre-implantation diagnosis, 5354 (22.3\%) pre-symptomatic, 609 (2.5\%) predictive, 146 (0.6\%) prognostic, 29 (0.1\%) recurrence, 5668 (23.6\%) risk assessment, 4741 (19.8\%) screening, and 154 (0.6\%) therapeutic management.

Discussion

There were a large number of registered genetic tests for a diverse set of genes focused on diagnosis, mutation confirmation, and/or risk assessment of germline mutations that could be passed to offspring. The majority of genes were successfully mapped to HGNC-approved gene symbols and NCBI RefSeq identifiers, consistent with one fundamental implementation guide’s recommendations for exchanging genetic information in health IT. However, most tests submitted to the registry did not include any assigned SNOMED CT code, highlighting the need for more effective (and required) linking of genetic tests to standard clinical codes that explain medical motivations behind test ordering\textsuperscript{6,7}. As precision medicine evolves from assessing genetic tests to applying sequenced genomes, robust informatics tools can provide valuable insight into the wealth of diverse data describing all aspects of healthcare IT\textsuperscript{8}.

An Empirical Analysis of Chaplain Charting Practices to Inform Electronic Health Record Template Redesign
Matthew Sakamoto, BS1, Rebecca Johnson, PhD1, M. Jeanne Wirpsa, MA, BCC1, George Handzo, BCC, CSSBB2, Linda Emanuel, MD, PhD1, Abel Kho, MD, MS1
1Northwestern University, Chicago, IL; 2HealthCare Chaplaincy Network, New York, NY

Introduction
With multiple care providers documenting in the electronic health record (EHR), it is important that these distinct disciplines chart in a way that facilitates intra- and inter-disciplinary communication. The healthcare chaplaincy is integral to understanding spiritual and religious beliefs as part of a comprehensive patient assessment, and to address related matters such as providing emotional support or initiating goals of care discussions1. Currently there are no standards for healthcare chaplaincy documentation. This study aims to describe the current state of healthcare chaplaincy documentation and identify important areas for improvement.

Methods
We conducted this study at an academic tertiary medical center with a Pastoral Care department and chaplaincy training program, where trainees also chart on patients. We looked at the NeuroSpine ICU (NSICU) that has chaplains integrated into clinical rounds. Chaplains use a Powerchart (Cerner) template with structured elements and an unstructured narrative note. We extracted Pastoral Care notes using a text-string search from our Enterprise Data Warehouse (EDW), and restricted our analysis to only experienced healthcare chaplains. We performed a descriptive analysis of healthcare chaplain utilization of structured data fields in the Pastoral Care EHR template. A manual review for themes in free text fields for 100 notes were compared to frequencies of corresponding structured data fields. We also conducted an informal mini-survey of NSICU providers to understand multidisciplinary team interaction with chaplains’ documentation.

Results
Our final analysis included 491 patient notes. Structured data items from the Pastoral Care template are grouped into four core domains and the frequency they were utilized were: Plan of Care, Referral source, Spiritual/Religious Affiliation, Spiritual Assessment. In the structured fields, analysis of the sub categories showed that the most frequently checked categories were: “Address anxiety through pastoral presence” (69%) for Plan of Care, Support systems in SR Resources (92%), Prayer in SR practices (75%), and Anxiety/Fear for SR concerns (81%). Initial thematic coding of narrative notes recorded by chaplains for the same patients suggests both convergence and divergence of topics between the structured and unstructured fields. Family support and specific SR practices were consistent in both structured and unstructured fields. Coders identified additional themes including records of care provided beyond prayer, and notes about the impact of SR care. These additional themes in the free text narrative do not have a corresponding structured data field.

Conclusions
Analysis of template documentation by chaplains in one hospital unit that integrates chaplaincy care identified the most commonly used categories within a spiritual and religious Plan of Care. Comparison of structured template data and the free text narrative notes suggests a richer narrative assessment of patients’ needs and identified several areas of improvement in our current template. We identified some potential key concerns documented by the chaplaincy which may be critical to the complete care of the patient (e.g. Do Not Resuscitate status). This study offers insight into the services provided by chaplaincy at one site, and an informal survey with NSICU providers suggest that the chaplain note is valued by the interdisciplinary team for eliciting spiritual concerns and aiding in goals of care discussions. Our findings have helped shape ongoing efforts to redesign the chaplaincy EHR template to better facilitate communication between the chaplains and the healthcare team, specifically establishing two categories of data: one for exclusive use by chaplains for patient continuity and strictly spiritual needs, and one for the rest of the medical team highlighting “Anxiety and Depression,” “Goals of Care,” “Family Coping” or “Religious/cultural beliefs that impact medical care.”

**Table 1.** Frequency of Utilization of Structured Data Fields in the Pastoral Care EHR Template
Improvement of cytokine annotation using ontology synonym mapping

Demetrios A. Sarantis, PhD1, Steven H. Kleinstein, PhD1,2, Kei-Hoi Cheung, PhD2,3,
1Department of Pathology, Yale University School of Medicine, New Haven, Connecticut;

Introduction

The quantity and variety of public data sets in the biomedical domain is rapidly growing, and there is increasing interest in leveraging this prior knowledge through integrative analysis. However, it remains a challenge to discover and integrate such data sets because they are annotated using different terminologies [1]. Mapping annotations to a standardized ontology can help unify terminologies to facilitate data integration. However, single ontologies may have limited coverage of term synonyms and thus can fail to recognize connections between data sets [2]. This research proposes Synonym Ontology Mapping (SOMA), an approach that integrates multiple ontologies to increase synonym coverage [3]. The approach has been tested and validated in the context of annotating cytokines in the immunology literature.

Methods

SOMA maps hierarchically related concepts between ontologies to a common root concept. To demonstrate the approach, we identify ontologies in BioPortal, which contain hierarchies rooted at the cytokine concept. For each of these ontologies, we retrieve all descending classes of the root class utilizing BioPortal search web services. For each descending class, SOMA extracts its identifier, preferred name, and synonyms (Figure 1). We output the extracted identifiers and terms for preferred names and synonyms to a file in RDF format that is a semantic web standard (http://www.w3.org/RDF). The advantage of using RDF graph representation is that we can use RDF tools, such as SPARQL, to query the data and connect them to linked data cloud (http://lod-cloud.net). The graph data are also stored in tabular format in a relational database in order to efficiently implement a synonym-chaining algorithm.

Results

We applied SOMA to the problem of named entity recognition, and constructed the Cytokine Ontology (CYTO) that contains 319 cytokines and 3566 synonyms integrated from ten ontologies available in BioPortal. The testing and validation of CYTO was made by annotating a large number of immunology-related abstracts from PUBMED. Whereas the best single ontology (Gene Ontology) could recognize 169 cytokines in a corpus of >371,000 articles, CYTO recognized 265 cytokines (an 58% improvement) (Figure 2). 727 synonyms, of the above 169 cytokines, would have been recognized using only Gene Ontology, while 1069 synonyms have been recognized using CYTO (an 47% improvement). While there is not any gold standard cytokine ontology, these results demonstrate that the annotation based on SOMA has more coverage than that based on any single ontology.

Discussion

Our work shows that ontologies integration based on synonym mapping increases cytokine term coverage and has the potential to guide development of community standards by identifying frequently used cytokine terms in the literature. During the mapping process (synonym chaining), imprecise synonyms have been identified as a key challenge. Synonym curation is needed to address this issue. Future work will incorporate more cytokine sources (e.g., existing cytokine database/lists) and extend SOMA to additional types of data (e.g., cell populations and cell surface markers). CYTO is publicly available through Bioportal (http://bioportal.bioontology.org/ontologies/CYTO).

A Framework for Individualized Prognosis of Disease Trajectories in Complex, Chronic Diseases: Application to Scleroderma, an Autoimmune Disease

Peter Schulam¹, Colin Ligon², Robert Wise², Laura Hummers², Fredrick Wigley², Suchi Saria¹,³
¹ Department of Computer Science ² Department of Medicine ³ Departments of Biostatistics, and Health Policy and Management
Johns Hopkins University, Baltimore, MD 21202 USA

Introduction: Precision medicine aims to prevent and treat diseases by tailoring management using individual-specific characteristics. Such approaches are especially poised to make an impact in diseases with heterogeneous presentation where treatment plans must vary based on the individual’s disease course. For example, patients with scleroderma, a systemic autoimmune disorder, show a variety of different patterns of disease activity. Individuals can develop complications of the lungs, skin, GI tract, heart, and kidneys to varying extents and at varying rates of progression [1]. Therefore, clinicians must guess which organs should be targeted with aggressive therapy (with potentially harmful side-effects). In many diseases, few biomarkers currently exist to accurately predict an individual’s course. Thus, we propose a computational framework that integrates diverse (static and time-varying) markers to predict the trajectory of a patient’s scleroderma-related lung disease. In addition to tailoring predictions, this dynamic inference procedure implements the vision of a learning health system that adapts and adjusts itself over time.

Methods: We develop a probabilistic framework that represents the disease activity trajectories at multiple resolutions: the population model captures effects that are shared across all individuals in the population, the subpopulation model captures effects specific to a subtype [1,2] --- a group of individuals with similar disease presentation --- and the individual model captures effects specific to a given individual. Population and subpopulation model parameters are learned offline while the individual-specific parameter estimates are refined as more data about the individual are observed. Personalized predictions are computed in real-time by using all of the data in the individual’s clinical history and marginalizing over the individual-specific parameters. Lung health is measured using a clinical marker called PFVC (% of predicted forced vital capacity). Our model uses the PFVC history of the individual to dynamically update predictions. In addition, it uses individual characteristics including demographic (gender and race) and serologic measurements (ACA and Scl-70 antibody positivity).

Results: Figure 1 shows the predictions obtained using the proposed framework for two individuals. Initial PFVC levels are comparable across both patients. After one year of followup, indicated by points (A) and (B), our model is able to correctly predict that the PFVC of the individual in the first row will remain stable, while the other will experience PFVC decline. After 4 years of data the confidence in each prediction is strengthened in spite of the sharp consecutive drop that both individuals exhibit--indicated by points (C) and (D). In particular, after a transient decrease in PFVC in the top patient at point (C) resulting from an episode of cholecystitis, the predicted PFVC trajectory appropriately continued to predict a largely stable course of lung disease. Using 10-fold cross validation on 672 patients, our model achieves mean absolute errors of 10.37, 8.95, and 6.98 when predicting PFVC values between 8-12 years of followup using 1, 2, and 4 years of data respectively.

Discussion: We have introduced a principled framework for integrating diverse clinical marker data to provide personalized prognosis of an individual’s disease trajectory. The proposed framework leverages the idea of refining predictions by modeling deviations at multiple resolutions --- deviations from the population that are common to a subpopulation and deviations across individuals within a subpopulation.

Are Meaningful Use Requirements Really Meaningful for Medication Use? Experiences from the Field and Future Opportunities

Abstract: The Agency for Healthcare Research and Quality (AHRQ)-sponsored Centers for Education and Research in Therapeutics (CERTs) critically examined the impact of MU policy relating to the use of medications. Stakeholders initially met in June 2014 to discuss the specific issues and developed recommendations to help inform future HIT policy. The consensus was that the MU objectives should acknowledge the diversity of healthcare systems and consider in particular EHR functionalities critical for the accurate prescribing of medications in children.

Introduction: To accelerate the deployment of health information technology (HIT), federal legislation provided substantial incentive payments to clinicians and hospitals for adopting and meaningfully using HIT. Meaningful use (MU) requirements aim to assure that electronic health records (EHRs) are utilized with meaningful effect to improve quality, safety, and efficiency of health care. The Agency for Healthcare Research and Quality (AHRQ)-sponsored Centers for Education and Research in Therapeutics (CERTs) critically examined the impact of the MU policy relating to the use of medications, and have jointly developed recommendations to help inform future HIT policy.

Methods: We gathered perspectives from a wide range of professionals representing academicians, practitioners, policy makers, and senior management officials from different healthcare organizations including and beyond the CERTs. Specific issues and recommendations were presented, discussed, and agreed upon as a group. We used the principles of consensus decision-making; all stakeholders were involved in the group discussions, encouraged to contribute opinions and suggestions, given the opportunity to build upon each other’s suggestions, afforded equal input into the process, and allowed to voice any particular concerns that they may have, so that the group could incorporate them into the emerging domains.

Results: Stakeholders’ knowledge and experiences of implementing MU requirements fell into six main domains: accurate medication lists and medication reconciliation, problem list accuracy and the shift in HIT priorities, accurate allergy lists and standards development, support of safer and effective prescribing for children, considerations for rural communities, and general issues with achieving MU. Stakeholders expressed concern about the lack of attention paid to pediatric prescribing, and highlighted the need for standards to better facilitate the exchange of data elements such as patient allergies between healthcare settings. Several organizations felt that their pre-occupation to fulfill MU
requirements stifled innovation at their site. Clinical analysts, engineers and senior programming staff were redirected to work on achieving MU and thus devoted less time to other more meaningful EHR development projects. The structural advantages of existing integrated delivery systems support ready adoption of some Stage 2 recommendations, such as the generation and electronic transmission of discharge prescriptions. However, other measures, such as Summary of Care documentation at time of transitions, required substantial resources to develop significant technical and operational change that affected an exceedingly small fraction of the patient population. Future MU requirements should put more emphasis on flexibly understanding, incorporating, and supporting local health IT configuration that address population health needs.

Discussion: While MU has stimulated EHR adoption, its effects on quality and safety remain uncertain. Stakeholders felt that MU requirements should be more flexible, and recognize that integrated models may be achieving information-sharing goals in alternate ways. Care should be taken to avoid MU requirements that are perhaps unnecessarily burdensome, to the mature, typically staff-model systems that have historically been the leaders in integrated use of clinical information. Better tools and interoperability with external data are needed for effective and efficient medication reconciliation. Future certification rules and requirements should in particular address EHR functionalities critical for the accurate prescribing of medications in children.
Detection of Colorectal Surgical Site Infections Using Bayesian Network and Natural Language Processing

Sunghwan Sohn, PhD1,2, Majid Rastegar-Mojarad, MS1,2,6, James M. Naessens, ScD1,3, Elizabeth B. Habermann, PhD1,3, David W. Larson, MD1,5, Hongfang Liu, PhD1,2

1Department of Health Sciences Research, 2Biomedical Statistics and Informatics, 3Health Care Policy and Research, 4Department of Surgery, 5Division of Colorectal Surgery, Mayo Clinic, Rochester, MN; 6Department of Health Informatics and Administration, UW-Milwaukee, Milwaukee, WI

Introduction
Colorectal surgery (CRS) is performed for various diseases and often requires major reconstruction of the gastrointestinal tract. Because of the number of indications for the surgery and disparities in the level of involvement in colorectal resections, the range of complications differs1. Surgical site infection (SSI) is the most common healthcare-associated infection, accounting for 31% of all hospital inpatient infections2 and resulting in increased length of hospital stay and cost. Over the past decade, accurate identification and monitoring of surgical complications have been emphasized to improve health care quality and to decrease financial costs. The American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) is one such effort. Previous studies have examined patient characteristics identified in NSQIP data to assess SSI risk factors1,3,4. These patient characteristics can be regarded as potential factors in predicting SSI, but they are not conclusive factors in identifying SSI. A thorough review of clinical notes is required to determine actual SSIs and this entails a great deal of time and effort. Natural language processing (NLP) and machine learning (ML) techniques represent promising alternatives to automate this process. In this study, we analyzed SSI risk factors for CRS and further applied a Bayesian network classifier to detect SSIs using variables of either or a combination of risk factors in NSQIP data and keywords extracted from clinical narratives by NLP.

Materials and Methods
We used NSQIP data from CRS performed at Mayo Clinic Methodist hospital from 2010 to 2012 combined with SSI indicative keywords from clinical notes of those cases. This consisted of 751 surgery cases with 67 SSIs (i.e., 36 superficial incisional SSIs, 5 deep incisional SSIs, and 26 organ/space SSIs). A Bayesian network was developed to detect SSIs using the following variables: 1) risk factors in NSQIP data; 2) keywords extracted from clinical narratives using NLP; 3) both 1) and 2); and 4) selected variables. The keywords are medical conditions associated with patients and represented by presence or absence. We used an open-source NLP pipeline, MedTagger, which was developed by Mayo Clinic (available in SourceForge), to extract keywords. Detailed descriptions of the variables are found in Table 1.

Results
Table 2 shows the ROC area under the curve (AUC) of the Bayesian network classifier using different sets of variables with 10-fold cross validation. The best performance was achieved when using both risk factors and keywords. The four selected variables, which were based on Chi-squared ranking, were able to produce higher AUC than using only risk factors. Without using these four variables, AUC was 0.729, which is close to using risk factors only. For comparison, a logistic regression was also employed (corresponding ROC curves are shown in Figure 1). The basic statistics and odd ratios of patient characteristics were also examined, and these are described in Table 3.

Discussion
Certain patient characteristics can be used as risk factors to predict SSIs. However, risk factors alone are not sufficient to accurately detect SSIs. The conclusive evidence, such as keywords from clinical narratives, must be examined thoroughly to better identify SSIs. The Bayesian network using both risk factors and keywords produced the strongest performance, although we used a limited set of keywords. Further refinement of keywords and ongoing assessment of risk factors are necessary to better detect SSIs. Automatic extraction of risk factors to implement near real-time SSI surveillance is also a next step. Informatics techniques such as NLP, which allows for the automatic extraction of patients’ medical conditions and statistical ML to predict the corresponding outcomes, are inevitable components in the realization of efficient SSI surveillance.

Clinical Language Annotation, Modeling, and Processing Toolkit (CLAMP) – a user-centric NLP system

Ergin Soysal, MD, PhD, Jingqi Wang, Min Jiang, Yonghui Wu, PhD, Hua Xu, PhD
School of Biomedical Informatics, University of Texas Health Science Center at Houston, Houston, TX

Introduction
Natural language processing (NLP) technologies play an important role of unlocking patient information in clinical narratives. Many clinical NLP systems have been developed – e.g. cTakes, MetaMap and MedLEE –, and applied in various applications such as identification of different clinical conditions. Despite the success of these systems, there are still barriers that preventing the widespread use of NLP tools by clinical researchers. For example, applying an existing machine learning module to existing data may not result in desired performances, and specific adaptations like re-annotating and re-training are always needed. However, this is a major obstacle for clinical end users with very limited informatics training. In this paper, we describe CLAMP, a natural language processing toolkit, which is designed to be used by non-technical users for clinical language processing, starting from annotation to training and testing models. The rationale behind CLAMP is to improve experience of end users.

Key Functionality
CLAMP is an NLP toolkit, consisting of an Eclipse based graphical user interface (GUI) (Figure 1) and an open source high performance language processing framework available at https://sbmi.uth.edu/ccb/resources/clamp.htm.

- NLP pipelines: CLAMP components builds on a set of high performance NLP components that were proven in several clinical NLP challenges such as i2b2 (2009-2010, NER #2), ShARe/CLEF (2013, abbreviation #1), and SemEVAL (2014, UMLS encoder, #1). A pipeline can be visually created and customized by chaining CLAMP components in the processing order. Upon creation of a component, CLAMP will check errors and direct user to appropriate logical order for a properly working pipeline. These components are supported by knowledge resources consisting of medical abbreviations, dictionaries, section headers, and a corpus of 400 annotated clinical notes derived from mtsamples.

- Machine learning and hybrid approaches: The framework provides alternative components for some tasks, utilizing rule based methods or machine learning methods using support vector machines, conditional random fields and Brown clustering. These components can be customized by re-training by an annotated corpus, or visually editing the rulesets within the GUI to achieve a custom NLP task. GUI also provides built-in functionality to test the model, using annotated test corpora or n-fold cross validation.

- Corpus management and annotation tool: The user interface accommodates required tools to maintain clinical text corpora. It hosts an improved version of BRAT annotation tool for clinical text annotations.

Evaluation
CLAMP components were tested using a couple of available corpus, suitable for the purpose. Rule based sentence boundary detection, named entity recognition (NER) and assertion components were tested using i2b2 corpus gold standard annotation. Rule based tokenization and section header identification utilizing lexical variant generator with SPECIALIST tested in UT Health corpus against gold standard annotation. OpenNLP based part-of-speech (POS) tagger component tested using 5-fold cross validation with MiPACQ corpus. UMLS encoder component was tested on SemEval-2015 corpus consisting of 431 clinical notes.

Results
Some performance metrics are summarized in Table 1 and Table 2. Accuracy for tokenizer, OpenNLP based POS tagger, section header identification, abbreviation and sentence boundary detection components were found as 0.98, 0.94, 0.96, 0.72 and 0.92 respectively. Overall f-measure for NER component calculated as 0.82 (p: 0.86, r: 0.79). Assertion component showed an f-measure of 0.94 (p: 0.94, r: 0.94. UMLS encoder a performance of 0.73 (accuracy) was reached with a processing speed of 1.5 sec/note.

Discussion
We presented open source CLAMP toolkit that aims to provide the best proven approaches using a mixture of dictionary based, rule based and machine learning methodologies in NLP as an easy to use desktop application for users with minimal or no technical experience. CLAMP toolkit also provides a high performance NLP framework that can be used with UIMA AS to implement more advanced scalable applications.

PCORnet Implementation of PopMedNet Data Characterization Tools

Jessica L. Sturtevant, MS1, Jessica M. Malenfant, MPH1, Melanie Davies1, Jose Rodrigues1, Laura G. Qualls, MS2, Lesley H. Curtis, PhD2, Jeffrey S. Brown, PhD1

1Harvard Pilgrim Health Care Institute, Boston, MA; 2Duke Clinical Research Institute, Durham, NC

Introduction
The National Patient-Centered Clinical Research Network (PCORnet) distributed research network (DRN) was established by The Patient-Centered Outcomes Research Institute (PCORI) in 2013. The network consists of 11 Clinical Data Research Networks (CDRNs) and 18 Patient-Powered Research Networks (PPRNs). The PopMedNet™ (PMN) platform was implemented across the PCORnet distributed research network in 2014 to help manage and facilitate network operations in support of multi-site clinical trials, comparative effectiveness research and cohort identification and characterization.

The PCORnet Common Data Model (CDM) - developed to facilitate cross-network research - is being adopted by all CRDNs and PPRNs. The PCORnet Coordinating Center (CC) is responsible for data characterization activities related to the CDRN and PPRN implementation of the PCORnet CDM. Data characterization is implemented using a distributed program that is executed locally by each CDRN/PPRN at each local data source. The data characterization output has a standardized structure - a data characterization data model - which allows PCORnet to leverage functionality developed by other distributed networks that use PMN. This data characterization data model is agnostic to the network CDM and allows any number of networks to use the PMN Data Characterization tool. The PMN Data Characterization tool allows for rapid, point-and-click visualization of aggregate metrics across the network.

Methods
Based on the standardized data characterization data model, PCORnet leveraged the PMN Data Characterization tool for race and ethnicity fields that were developed by FDA without any additional software development. Output was obtained from CDRN DataMarts allowing for rapid visualization of the race and ethnicity distribution across the network.

Data characterization metrics that are rapidly accessible will be valuable to the developing PCORnet DRN and will facilitate research. The ability of the PCORnet CC to leverage existing PMN functionality demonstrates the extensibility and cross-network functionality that is a goal of PCORnet. The standardized data characterization data model allows for this cross-network sharing of PMN functionality.

Results
The first PCORnet data characterization queries were designed to capture data elements for race and ethnicity to assess and visualize key characteristics such as missingness and frequency. The PCORnet query was pilot tested to demonstrate the ability to utilize the PMN Data Characterization tool leveraging capabilities originally developed for use by other networks and now embedded in the PMN platform. This pilot demonstrated the ability to quickly implement the PMN Data Characterization tool to visualize the distribution of race and ethnicity among CDRNs.

Conclusion
PCORnet data characterization will encompass over 55 CDRN site data sources and at least 20 PPRN site data sources. Visualizing and describing the characteristics of these diverse data sources that include clinical, claims and patient-reported data is facilitated and simplified in utilization of the PMN Data Characterization tool. This is a novel approach to inform data queries and to investigate data sources in preparation for research requests or clinical trial participant identification.

PCORnet benefits from the cross platform utilization of existing PMN tools and simultaneously contributes new developments that may be leveraged by other networks. Future work will include enhancing the Data Characterization tool to include other relevant data elements, refined access controls and interactive visualization design and reports. Future PCORnet contributions to this functionality will be incorporated into the PMN platform that can then be leveraged by any number of other networks.

Rapid, easy access to high level data descriptive statistics by site and network will help PCORnet assess data usability for varying purposes prior to investing time on code development and data source investigation.
Efficiency and Accuracy of Kinect and Leap Motion Devices Compared to the Mouse for Intraoperative Image Manipulation

Uchenna A. Uchidiuno, MS1, Yuanyuan Feng, MS1, Hamid R. Zahiri, MD2, Ivan George2, Adrian Park, MD, FACS2, Helena Mentis, PhD1

1University of Maryland Baltimore County, Baltimore, MD; 2Anne Arundel Medical Center, Annapolis, MD

Introduction

Touchless interaction devices such as the Microsoft Kinect and Leap Motion device have been proposed for medical image manipulation during surgery1,2. Studies have shown that touchless devices have the potential for alleviating the concerns of maintaining a sterile environment, reducing surgery time, and enabling surgeons to be more autonomous in carrying out various image manipulation tasks required during surgery3. Although these previous studies1-3 have shown the potential of these touchless devices, there is a need to investigate the efficiency and accuracy of these devices compared to the mouse. Prior work has shown that the Kinect can be as efficient and accurate as the mouse, but it is unclear if task type has a mediating effect and these studies have not formally tested the devices with the intended end-user group4,5. In the following study, we carried out a controlled lab-based evaluation of two touchless interaction devices with five different tasks by ten surgeons: the Microsoft Kinect and the Leap Motion. Our study aimed to answer two research questions: 1) how well does touchless interaction compare to a mouse on metrics of accuracy and efficiency and 2) does task type lend itself better to one interaction device over another.

Methods

We used the TedCas plugin for ClearCanvas DICOM viewer to display and manipulate anonymized CT images of a head. TedCas provided the following five image manipulation techniques: step-through, pan, zoom, circle measure, and line measure. The experiment compared three input devices: a standard wireless optical mouse with a sterile covering, the Kinect, and the Leap Motion sensor. Each participant performed each of the five image manipulation techniques five times using each of the input devices. The sequence of tasks and devices were counterbalanced across participants. Data collected was video of each participant captured from the front and a screen capture of the display allowing us to record the completion times and number of errors. A total of ten experienced surgeons participated in the study (see Table 1). The Anne Arundel Health Systems and University of Maryland Baltimore County IRB approved the study and participant consent was acquired. Statistical analysis was performed with SPSS version 22 (Chicago, IL). We carried out a 3 by 2 (Device x Run) ANOVA for both task completion time and errors.

Results

For efficiency, a repeated measure analysis for zoom, pan, line measure and circle measure showed that there is no significant difference between each device in terms of completion time (Figure 1). For the step-through task, there was a significant main effect of Device on Time, F(2, 16)=43.155, p<.001, η2 = .844 (Figure 2). Post-hoc tests using the Bonferroni correction indicated that the mouse was significantly faster than the touchless devices and the Leap Motion was significantly faster than the Kinect. For accuracy, a repeated measure analysis for zoom, step-through, line and circle measure showed that there is no significant difference between each device in terms of errors (Figure 3). The pan task had a significant main effect of Device on Errors, F(2, 18)=4.936, p<.05, η2 = .354. Post-hoc tests using the Bonferroni correction indicated that the mouse had significantly fewer errors than the Kinect or Leap Motion device (Figure 4).

Conclusion

Evaluating the efficiency and accuracy of touchless interaction devices against the mouse gives a better understanding of the benefits and limitations of these devices. We found that the mouse maintains its overall accuracy and efficiency for most tasks. However, for certain image manipulation tasks i.e. zooming, line measure and circle measure, there is no significant difference between the performance of the mouse and the touchless input devices. Both the Microsoft Kinect and Leap Motion device have great potential for adoption in the OR for image manipulation, but there is need for improvement in certain areas if they are to replace the mouse.

⁴NewYork-Presbyterian Hospital, New York, NY

Abstract: Nearly 20% of hospitalized Medicare fee-for-service enrollees are readmitted within 30 days. Outpatient physicians’ use of interoperable electronic health records may reduce readmission rates. We compared the odds of rehospitalization before and after Meaningful Use for patients of physicians who participated in the program with patients of matched control physicians. Relative to the control group, physician participation in Meaningful Use was associated with 7.5% lower odds of rehospitalization (Odds Ratio: 0.925, 95% confidence interval: 0.860-0.996).

Introduction: Nearly one-fifth of hospitalized Medicare fee-for-service (FFS) enrollees are readmitted within 30 days.[¹] Use of interoperable electronic health records (EHRs) among outpatient physicians may reduce rates of rehospitalization. Meaningful Use has made nearly $30 billion available to encourage provider adoption and use of interoperable EHRs.[²] The objective of this study was to evaluate the impact of outpatient physicians’ participation in Meaningful Use on rehospitalization of Medicare FFS enrollees.

Methods: The study population included 102,857 Medicare FFS enrollees from the State of New York hospitalized over the period 2010-2012. We compared changes in the odds of 30-day rehospitalization before and after the implementation of Meaningful Use for patients attributed to physicians who participated in the program with patients attributed to a matched group of control physicians. Odds ratios were estimated using logistic regression models with hospital and physician fixed effects. Two sensitivity analyses were conducted, one of sicker patients with 3+ Elixhauser co-morbidities and another of patients hospitalized for acute myocardial infarction (AMI), congestive heart failure (CHF), or pneumonia, three conditions targeted by Medicare to penalize hospitals with high rates of readmission.

Results: The characteristics of patients attributed to physicians who participated in Meaningful Use were similar to those of patients attributed to physicians who did not participate in the program during the study period (Table 1). After adjusting for patient, hospital and physician characteristics, patients attributed to physicians participating in Meaningful Use had 7.5% lower odds of rehospitalization (Odds Ratio [OR]: 0.925, 95% confidence interval [CI]: 0.860-0.996) compared to patients attributed to physicians who used paper records. ORs from analyses of patients with 3+ Elixhauser co-morbidities and those with AMI, CHF, or pneumonia were 0.928 (95% CI: 0.869-0.990) and 0.882 (95% CI: 0.771-1.010), respectively. In all analyses, patients of physicians with EHRs who did not participate in Meaningful Use had the same risk of readmission as patients of physicians who used paper records.

Discussion: Physician participation in Meaningful Use may reduce the likelihood of rehospitalization among Medicare FFS enrollees. Patients with conditions associated with high rates of readmission may benefit more from physician participation in the program. Our findings represent the first evidence of the impact of physician participation in Meaningful Use on the quality and utilization of care among the Medicare FFS population.

Toward the Development of a Predictive Model for Patient Portal Adoption by Patients in a Federally Qualified Health Center

Theresa L. Walunas, PhD¹, Richard Kalu, MD¹, Matthew Sakumoto¹, Kathryn Jackson, MS¹, Sarah Rittner, MA², Timothy Long, MD²,³, Mita Sanghavi Goel, MD, MPH¹  
¹Northwestern University, Chicago, IL; ²Alliance of Chicago Community Health Services, Chicago, IL; ³Near North Health Services Corporation, Chicago, IL

Introduction
Patient portals provide online access to health records and allow for secure communication with clinicians, test result review, and medication refill requests. Patient portals are critical for achieving meaningful use of electronic health records (EHR) and improving patient centered care, yet studies show disparities in use of patient portals, particularly by African-American populations. In order for health care organizations to improve use of portals, it is important to understand factors that predict adoption and use of portal technologies. The technology acceptance model (TAM) has been used to explain and predict adoption of technology in many environments, but has not been applied to patient portals. To determine if the TAM could be used for portals, we focused on how perceived ease of use (PEOU) and perceived usefulness (PU) of the portal varies by basic demographics and health conditions amongst a patient population at one urban Federally Qualified Health Center (FQHC).

Methods
Prior to implementation of the patient portal at an FQHC with a predominantly African-American patient population, we conducted an in-person survey among a convenience sample of 149 participants. We collected demographic data (age, gender, race/ethnicity, educational attainment, number of existing chronic health conditions in EHR problem list) along with the type and level of technology use. Participants’ ages were categorized as ≤35, 36-50, and 51+ years, and their education as ≤GED, some college, and ≥college graduate. We assessed and compared their PEOU and PU of a portal system. In addition to baseline descriptive analyses, we conducted chi-square tests comparing each domain (PEOU, PU) by demographic characteristics (age, gender, educational attainment, chronic conditions). P<0.05 was considered statistically significant for all analyses.

Results
The mean age of participants was 46 years; 96% were African-American, 61% were women; 28% had a GED or less formal education; 47% had 1 or more chronic conditions. There was a high level of technology use: 78% of participants had a computer, 98% had a cell phone, 89% owned a smart phone, and 83% used the Internet daily. Of the questions measuring PEOU of portal technology, we found few significant differences by age, gender, education or chronic conditions (see Tables 1 and 2). Older participants were more likely to perceive the portal as time consuming (24% of 51+ vs. 5% of ≤35, p<0.05). Men were more likely than women to perceive portals as too complicated to use (30% vs. 14%, p<0.05). Those with 3+ chronic conditions anticipated it would be harder to use compared to those with none (60% vs 87%, p<0.05). Those with higher levels of formal education reported lower rates of PEOU: more reported it was time consuming (25% of college grads vs. 7% of ≤GED, p<0.05) and it was too complicated to use (35% of college grads vs. 7% of ≤GED, p<0.05); fewer reported it was easy to use (73% of college grads vs. 85% of ≤GED, p<0.05) and that learning to operate the patient portal will be easy (68% of college grads vs. 95% of ≤GED, p<0.05). We did not find many differences by age, sex, and education for the PU questions related to features of the patient portal (see Table 3). The few differences were: participants aged ≤ 35 years valued the ability to email their doctors or complete pre-clinic appointment tasks online compared with older participants. Women valued the ability to schedule recommended screening tests, as well as view their clinic notes online, more than men. Finally, patients with 3+ chronic conditions had less value for using the portal to ask questions about medical issues and reviewing current medications compared to patients with fewer chronic conditions.

Conclusions
In this single FQHC site study, we observed an overall high level of technology ownership and use amongst the patients surveyed. PEOU of portal technology varied substantially by level of formal education. Surprisingly, those with higher educational attainment were more apprehensive about ease of use of the system. On the other hand, there were few variations in areas of PU, with most participants placing a high value on communicating with their doctor and managing their care through the portal. Achieving Meaningful Use of EHR and preventing worsening of disparities in portal uptake requires attention to ensuring and emphasizing the ease of use of these systems, especially among those with higher levels of education.

A Not So Lame Outlook for Injured Farm Workers: Return to Work Software Application Development

Bryan Weichelt, MS, MBA, PMP¹, Iris Anne Reyes, MPH¹, Andrea Mahnke, MS², William Ray, BS², Laurel Verhagen, BS², Shaun Halstead, BS², and Matthew Keifer, MD, MPH¹

¹National Farm Medicine Center, Marshfield Clinic Research Foundation, Marshfield, WI; ²Biomedical Informatics Research Center, Marshfield Clinic Research Foundation, Marshfield, WI

Abstract

Serious, restrictive, non-fatal injuries are commonplace in large animal agriculture including in pork and dairy production. Primary care clinicians often have few resources to facilitate workers’ return to work. This project will develop a return to work software program to produce applicable light duty job assemblies (LDJA). One of the significant challenges is the integration of Physical and Occupational Therapists’ unstructured narrative data collection methods into structured data.

Introduction

Large animal farms are growing in size, increasing in work task specialization and hiring more immigrant labor. Workers not only face inherent risks in the agricultural workplace, but are also introduced to significant dangers in these operations. A range and variety of injuries in pork and dairy farms are common and are increasingly managed by primary care physicians. Yet, clinicians are often unfamiliar with the physical demands of farming and have little training and few resources to manage the return-to-work of injured workers.

The project utilizes examples of representative pork and dairy facilities to describe workflow, feasibility and impact of returning workers into the various LDJA positions. To create the LDJAs, the project is developing a computer application designed for clinicians, to guide early return-to-work planning for injured workers in the dairy and pork industries.

Methods

With assistance from the Marshfield Clinic Research Foundation’s Interactive Clinical Design Institute, we focused iterative design and prototype development on the needs of the users – clinicians, farm workers, and farm owners/managers. Focus groups of English and Spanish-speaking farm workers were conducted. One-on-one interviews with six different Marshfield Clinic clinicians led to significant design changes, shifting to a design that closely resembles the current Workers’ Compensation form used throughout the organization.

Physical and Occupational Therapists collected detailed functional job and task measurements on 32 implement dealers, dairies, and pork farms. The software application has several key components: 1) database of functional job profiles, 2) a clinician interface and input form, and 3) customized return-to-work output sheets for farm owners and their injured workers available in English or Spanish.

The functional job profile database consists of hazards and physical demands for common farm tasks collected by physical and occupational therapists. The clinician interface allows the provider to electronically enter restrictions. Algorithms automatically produce alternative job assemblies within the injured worker’s limitations. Lastly, simpler return-to-work output sheets are customized for owners and workers, replacing the traditional form.
Results

Physical and Occupational Therapist data collection is often based on a narrative and detailed approach. Limiting this input to structured elements allowed for algorithmic precision, but also hindered the collection and entry process, leading to four different input forms, including 24 versions of the field data collection form, which was developed in Microsoft Word.

Focus groups, interviews and usability tests with users were conducted throughout the development phase. Clinicians who were interviewed were aware of the usability issues of the complex return-to-work form currently used in practice but believed that the complexity was necessary. They expressed the desire to learn more about tasks on the farm through photos and videos, but felt that they had little time to do so.

Farm owners and workers preferred a simpler return-to-work form with lay person terms and would also like additional handouts regarding the injury or illness. All groups felt that the creation of a Spanish version of the form would be helpful for Spanish-speaking workers and their families.

Discussion

This project addresses an unmet need in agricultural safety and health – connecting the clinician to the farmer to reduce disability and sustain an adequate, safe workforce for the growing agriculture industry. It has also illuminated the significant challenge of addressing the unstructured data collection norms of Physical and Occupational Therapists in the field. The project identified those challenges, refined data collection and data entry tools and processes and developed new standards to accommodate.

Pruning descriptive value of agricultural tasks was an acceptable compromise to ensure a functional prototype was available for future testing in a clinical setting. To counter this, future research should include an evaluation of image files, .gif files, and video files as a replacement of descriptive narrative within the application.

This project closely links to several projects with a focus on injury and risk reduction in dairy production as part of the Upper Midwest Agricultural Safety and Health Center, whose overarching goal is to address health and safety issues faced by agriculture producers, workers, and their families in the Upper Midwest.
A Guideline for Assessing EHR Data Quality for Secondary Use
Nicole G. Weiskopf, PhD1, Chunhua Weng, PhD2
1Oregon Health & Science University, Portland, OR; 2Columbia University, New York, NY

Abstract
The reuse of electronic health record (EHR) data promises to increase the efficiency and generalizability of clinical research. EHR data, however, are known to be of poor and variable quality, which may decrease the validity of research findings. Researchers and informaticians require tools that allow them to select, perform, and report appropriate data quality assessments. We describe the formulation, development, and intended use of 3x3 DQA (Data Quality Assessment), a novel dynamic guideline for EHR data quality assessment.

Introduction
The secondary use of EHR data may circumvent some of the limitations of traditional prospective research, such as inefficiency and lack of generalizability.1-3 Unfortunately, it has been demonstrated that EHR data are generally of poor and highly variable quality.4-6 EHR data quality assessment must be transparent, task-dependent,7 systematic, evidence-based, and not reliant upon the availability of gold standard data. 3x3 DQA was designed to be responsive to the above principles. It is the first comprehensive guideline designed to mitigate and make transparent the effects of data quality on research validity through a systematic but task-dependent approach.

Methods
We conducted a series of studies to develop the guideline. Our approach combined qualitative studies of the attitudes and opinions of clinical researchers regarding their concerns about EHR data quality, systematic review of the informatics and data quality literature,8, 9 and quantitative analyses of EHR data quality.10 Through triangulation of the above, we derived a set of principles to guide contextual, task-dependent EHR data quality assessment.

Results
Version 1.0 of 3x3 DQA includes a user guide, questions to identify the data quality requirements of a study, a framework, and assessment and reporting recommendations. The guideline, which is intended to be used by informaticians and clinical researchers conducting clinical research with EHR-derived data, was developed for epidemiological study designs, though it may be extensible to other use cases.

The framework (Figure 1), which serves as the conceptual foundation of the guideline, features three constructs of data quality operationalized across three dimensions of the data. Because data quality is task-dependent, the guideline must be used for a specific dataset and associated research question(s). Once a study has been planned and a dataset has been extracted, a user steps through a series of questions to identify the relevant constructs, data dimensions, and assessment steps. This information then maps directly to the operationalizations (one per cell) in the framework. Each operationalization is in turn linked with a detailed methodological recommendation for assessment and reporting (Figure 2).

Discussion
Based on early expert feedback and user responses, 3x3 DQA has so far been well received by the EHR data quality community, though further work is warranted. A handful of projects using the guideline are underway. We are in the process of improving the clarity and usability of the guideline in response to user feedback. We intend to automate the guideline to reduce user burden and are planning a formal, scenario-based evaluation of the guideline.

Conclusion
3x3 DQA represents one of the first comprehensive methodological approaches to EHR data quality assessment. It is intended to enable researchers and informaticians engaged in the secondary use of EHR data to make determinations regarding the suitability of their data for their intended research and to conduct that research with greater confidence in the validity and trustworthiness of their results.

Making Hypertensive Medication Data Meaningful

Richard Williams, MA (Cantab)1,2, Benjamin Brown, MRCGP, MSc2, Niels Peek, MSc PhD1,2, Iain E. Buchan, MD, FACMI1,2

1 MRC Health eResearch Centre; 2 NIHR Greater Manchester Primary Care Patient Safety Translational Research Centre, University of Manchester, Manchester, UK.

Introduction

Primary care research databases derived from UK electronic health records (EHRs) contain coded prescription information. Much of this information is unstructured or unordered, and interpretation is required to assign clinical meaning to it. A common approach is to obtain the total mg of drug prescribed to a patient in a given time window and then calculate an average daily dose or exposure1-3. Another approach to inferring drug exposure is to count the number of prescriptions of the drug over the study period3-5, or in two adjacent time windows6. These approaches are valid if the dosage or presence of a drug is considered as a single covariate, however, to contextualize prescribing to the clinical decisions made on care pathways it is necessary to convert the EHR data into events, such as when therapy is commenced, terminated or changed. These events can then be used in a variety of analyses and tools such as: monitoring patient adherence to medication; care pathway analysis including process mining; next-generation phenotyping7; realistically-complex quality indicators; and advanced audit. Here we focus on medications prescribed for hypertension.

Method

We used an anonymized extract of primary care data from 53 general practices in Salford, UK (population 234k). The data contains Read codes (version 2) and EHR vendor-specific codes. All prescriptions of drugs recommended by the National Institute for Health and Care Excellence (NICE) for the treatment of hypertension8 in the UK were extracted. We created a mapping between each drug code, the active ingredient(s) and the tablet dose (mg). We found 653 Read codes and 199 vendor specific codes, covering 178 brand names and 70 generic names of antihypertensive medications. Text mining, using regular expressions, on 216,101 distinct textual patient instructions yielded the number of tablets taken per day. We then iteratively developed an algorithm to take the amount, frequency, duration and type of medication, together with the prescription date to extrapolate meaningful events as shown in Table 1 and Table 2. The iterations continued until the proportion of unclassified events achieved an acceptably low level. The algorithm was then validated by two authors (RW and BB, a clinician) who independently reviewed the records of a random sample of 100 patients to determine if the correct sequence of events had been extracted, and if not, recorded the discrepancy. Cohen’s κ showed fair inter-rater agreement (0.45). Disagreements were resolved through discussion.

Results

The algorithm was developed over 6 iterations involving the detailed examination of 179 patient records. A total of 10,311,973 prescriptions were extracted for 81,096 patients over the period 7 July 1977 to 12 December 2014 (54% female / median age 64, IQR [50, 77]). The breakdown for each family of drugs is shown in Table 3. The algorithm produced sequences with a combined total of 850,028 events (28% starts, 34% stops, 15% restarts, 16% increases, 8% decreases and 0.02% unclassified). During validation the algorithm achieved a PPV of 92% (95% CI 85%-96%). Of the 100 records reviewed only 8 had incorrect sequences and these were still partially correct. Four were missing a single stop event, two were false increases due to an erroneous prescription, one had an extra stop event, and one had a decrease for a switch from 2.5mg indapamide to 1.5mg modified release; these are actually clinically identical.

Discussion

We have developed a method for transforming unstructured prescription data into clinically meaningful events on a care pathway from EHR data. From these events it is easy to determine: when a patient is taking a medication; when there are adherence issues; when an intervention is or isn't made by a physician; when guidelines are being followed correctly; and if treatment is having the desired effect. We plan to incorporate these events into care pathways of chronic conditions in order to perform variance analysis to discover how variation from a pathway affects patient outcomes. The algorithm has the potential to be improved further by addressing the occasions where an incorrect sequence was produced. Strengths: The iterative nature of the design, high PPV, and clinically meaningful output. Limitations: We do not have information as to whether prescriptions were collected or taken. However, the act of prescribing is close to the clinician-centered decision context of care pathways.

Improving Weight in Patients with Serious Mental Illness: A Randomized Controlled Trial of Computerized Weight Services with Peer Coaches

Alexander S. Young, MD, MSHS1,2, Amy N. Cohen, PhD1,2, Richard Goldberg, PhD3
Julie Kreyenbuhl, PharmD3, Fiona Whelan, MA2
1Department of Veterans Affairs, Los Angeles, CA, USA; 2UCLA, Los Angeles, CA, USA; 3Department of Veterans Affairs, Baltimore, MA, USA

Abstract

In-person weight management interventions improve outcomes of people with serious mental illness. However, these require extensive time from patients and clinicians, and are rarely provided in usual care. We studied whether barriers could be addressed using computerized provision of diet and exercise education and decision support, combined with motivation from peer coaches.

Introduction

People with serious mental illness are at high risk for obesity and related medical problems, and die 10 to 20 years prematurely, most commonly from cardiovascular disease. Guidelines recommend specialized, in-person weight management interventions. These result in weight loss when delivered in efficacy trials done with motivated patients who are often paid to participate. In usual practice, these interventions are rarely provided, and, when provided, patient enrollment and retention are low. Interventions require substantial clinician time and frequent clinic visits for patients. We studied whether these barriers could be addressed using computerized provision of diet and exercise education and decision support, combined with motivation and support from peer coaches.

Methods

Randomized, controlled, comparative effectiveness study, conducted with overweight patients with serious mental illness at mental health clinics. 276 patients were recruited from a Veterans Affairs medical center, and 54 patients recruited from a county mental health clinic. Patients were randomized to 1) online weight management with peer coaching, 2) in-person clinician-led weight services, or 3) to continue with treatment as usual. Online weight management included 30 modules plus weekly telephonic peer coaching. The online system could be accessed from clinic kiosks, or anywhere there is internet access. It provided simultaneous audio and text-based education, video, pedometer tracking, goal setting, homework, diet plans, and quizzes. Coaching was delivered by individuals with lived experience with mental illness, was phone-based, and utilized motivational interviewing principles. In-person weight management had the same curriculum as the online program. At 6 months, patient outcomes were assessed.

Results

A mixed measures repeated model predicted Body Mass Index (BMI) at 6 months while controlling for site and BMI 6 months prior to entering the study. 271 individuals were obese at baseline (BMI > 30). In obese patients, there was a significant group by time interaction (F=3.4, p=.03). The online and peer coaching group had weight loss averaging 0.8 ± 0.2 BMI points (5 pounds; p<.01). No change was seen in treatment as usual (p=.42) or in-person services (p=.57). No effect was seen in patients with BMI < 30. 21% of patients completed the on-line program compared to 0% completing all in-person groups (χ²=19.7; p<.0001). The on-line intervention was well received.

Discussion

On-line weight management with peer supports can provide educational content and decision support that is tailored to individual patients, and patient-centered. It is feasible in usual care settings, has little burden on clinicians, and marginal costs are low. It produces weight loss, and may have greater effectiveness than clinician-led services. Patient motivation remains a critical challenge to spreading weight interventions beyond efficacy trials in highly select samples. Informatics technology and peer supports show the potential to enhance motivation, though continued innovation can strengthen mean outcomes in usual care populations.

Abstract Title: Iterative design and evaluation methodology for clinical decision support systems

Authors: Fei Yu, PhD, Vincent Carrasco, MD, Ketan K. Mane, PhD, Javed Mostafa, PhD

Introduction: Wide adoption of CDS systems among physicians remains an elusive goal. The MindsEye project was initiated as a collaboration among UNC informatics researchers and clinicians to respond to this need. The goal of this project was to provide an interactive user interface (UI) that: organizes and presents data by visualization; allows sorting, sifting, and re-organization of data on demand and seamlessly integrates with healthcare practice workflow, as well as evaluating a new UI for the treatment of outpatient psychiatric patients (Figure 1).

Methods: An iterative development and evaluation methodology was adopted and implemented as a two-phase strategy. Phase I concentrated on design, evaluation and refinement. Pilot users (n=6) provided feedback on a range of tasks. This data was carefully aggregated, analyzed and converted to UI refinements. Subsequently, a more comprehensive study was conducted, with the refined interface, as Phase II (n=19). Both phases consisted of a 4-step usability process: pre-test questionnaire, UI orientation session, monitored task performance session, and post-test questionnaire (Table 1). The monitored task performance stage used a think-aloud protocol during the task sessions. The subjects’ opinions, comments, and feelings were recorded. At the end of the post-test survey, a discussion session was held with each subject to clarify the collected comments and feedback. A video-based screen capturing software, called Camtasia, was used to record all task sessions for analysis and evaluation.

Results: Data from Phase I and Phase II were compared (Tables 2, 3, and 4). Comparatively, Phase II subjects demonstrated improved performance and satisfaction. On critical features, the results were consistent across both phases. For example, Timeline view was consistently rated highest on like-ability whereas the treatment guideline feature was poorly rated in both phases. The forecasting section yielded inconsistent results between two phases. It was generally observed that the like-ability factor and the subject task performance did not correlate in either phase.

Discussion: Overall, this iterative UI design and evaluation methodology proved useful and produced superior user performance and satisfaction on critical features of the refined version of the UI. Among all the UI features, physicians consistently rated Timeline view the best. However, they requested further refinements. Another important lesson we learned was that design and evaluation techniques require flexibility to accommodate the dynamic clinical ecosystem.

Improving Retrieval of PubMed Articles Using the TopicalMeSH Representation

Zhiguo Yu, MS¹, Elmer Bernstam, MD, MSE¹, Trevor Cohen, MBChB, PhD¹, Byron C. Wallace, PhD², Todd R. Johnson, PhD¹
¹The University of Texas School of Biomedical Informatics at Houston, Houston, TX; ²School of Information, University of Texas at Austin, Austin, TX

Introduction
Medical Subject Headings (MeSH) was developed by the US National Library of Medicine (NLM) to better manage and search large volumes of articles in MEDLINE. But MeSH has several limitations, including: the lack of concept coverage for newly developing areas; human inconsistency in assigning codes; and the time required to manually index an exponentially growing corpus. In contrast, probabilistic topic modeling approaches can automatically index and summarize corpora. An important practical question is whether automatically generated topics have any advantage over MeSH indexing alone. To address this question, we introduced the TopicalMeSH representation for biomedical literature by leveraging the correspondence between latent topics (uncovered via topic modeling) and MeSH. We evaluated TopicalMeSH as a representation for document retrieval and classification on a corpus comprising 15 drug reviews. TopicalMeSH performed better than MeSH alone in both of these tasks.

Method
Chuang et al. developed a topic model evaluation framework by computing a correspondence matrix of reference topics assigned by domain experts and latent topics recovered by Latent Dirichlet Allocation (LDA). LDA is a generative model that considers each document to be a mixture of latent topics, and defines these topics as distributions over words. We propose a variation of this method to compute the correspondence between MeSH terms and topics generated by LDA. To compute the similarity score between inferred topics and MeSH, we represent each MeSH term as a distribution of the words contained in documents that were tagged with that MeSH term. Figure 1 depicts our approach schematically. Compute Correspondence Matrix uses the rescaled dot product defined below to calculate the similarity score of each MeSH term-topic pair. $M_5$ is the Topic-to-MeSH correspondence matrix. $M_6$ is our document-to-TopicalMeSH matrix, which is the matrix product of $M_5 \times M_4$. This matrix relates MeSH terms to documents in which corresponding topics feature prominently. We used two tasks to evaluate the utility of the TopicalMeSH feature matrix $M_6$ and the original MeSH features in Matrix $M_1$.

\[
\text{Re} \text{scaled Dot Product} = \frac{\hat{p}_Q - d_{\text{ms}}}{d_{\text{ms}} - d_{\text{ms}}}; \quad d_{\text{ms}} = \frac{\hat{p}Q}{\hat{q}}; \quad d_{\text{ms}} = \frac{\hat{p}Q}{\hat{q}}; \quad \hat{p} \text{ and } \hat{q} \text{ are vectors consisting of all unique words in descending order}; \quad \hat{q} \text{ is in ascending order.}
\]

The first task was a document retrieval task. We mapped the user's information needs (for a systematic review) to candidate relevant MeSH terms. We used these MeSH terms, both directly and via TopicalMeSH, to rank documents and then calculated the Mean Average Precision (MAP) achieved using these representations. The second evaluation was a classification task, in which we applied a supervised machine learning method to the corpus to learn to classify documents with respect to their relevance. We used Support Vector Machines (SVMs) to compare the performance ($F_1 =$ harmonic mean of recall and precision) of the following five different representations: MeSH, TopicalMeSH, Words, MeSH+Words, TopicalMeSH+Words. For both tasks, we used 15 systematic drug review corpora reported by Cohen et al.

Results
Table 1 shows the results of the document retrieval task. TopicalMeSH achieved a higher MAP score in 11 of 15 corpora. The average MAP improvement from MeSH to TopicalMeSH was about 5%. For the classification task, Table 2 shows the results for SVMs that performed best. Again, TopicalMeSH achieved a higher $F_1$ in 14 of 15 corpora compared to MeSH. TopicalMeSH+Words had a higher $F_1$ than MeSH+Words in 11 of 15 corpora (Table 2).

Conclusion
The TopicalMeSH representation we propose, which combines latent topics and corresponding MeSH terms, improves performance on information retrieval and document classification tasks involving PubMed abstracts.

Towards Computational Drug Repositioning: A Comparative Study of Single- and Multi-task Learning

Ping Zhang, PhD\(^1\), Zhaonan Sun, PhD\(^1\), Fei Wang, PhD\(^2\), Jianying Hu, PhD\(^1\)
\(^1\)IBM T. J. Watson Research Center, Yorktown Height, NY; \(^2\)University of Connecticut, Storrs, CT

Introduction

In response to the high cost and high risk associated with traditional de novo drug discovery, investigation of potential additional uses for existing drugs, also known as drug repositioning, has attracted increasing attention from both the pharmaceutical industry and the research community. We hypothesize that diseases are related to each other, and learning multiple related tasks simultaneously could improve the prediction performance of drug repositioning. In this study, we propose a multi-task learning (MTL) framework to generate drug repositioning hypotheses and compare it with single-task learning (STL) strategy.

Methods

We collected 1255 drugs from DrugBank. Each drug was represented by an 881-dimensional binary profile whose elements encode for the presence or absence of each PubChem substructure by 1 or 0, respectively. The known uses of these drugs were collected from MEDI database \(^1\). Indications in MEDI were coded as ICD9 codes. We grouped ICD9 codes based on their first 3 digits to avoid trivial predictions (i.e., repurpose a drug from a disease to very similar diseases). Also, we excluded non-disease conditions and rare diseases, and obtained 100 ICD9 groups as diseases in our drug repositioning experiment. Between our 1255 drugs and 100 diseases, there are 3430 distinct drug-disease interactions in the dataset.

We modeled the drug repositioning task as a binary classification problem. We constructed a classifier for predicting whether a given drug could treat a particular disease or not, and repeated this process for all 100 diseases. In the scenario of STL, such 100 tasks are solved independently, ignoring the task relatedness. However, the tasks of predicting disease indications of drugs are related (as a disease might associate with other diseases in real life). In MTL, these related tasks are learnt simultaneously by extracting and utilizing appropriate shared information across tasks. Figure 1 illustrates the difference between STL and MTL.

In our study, we used logistic regression as the base classifier to compare STL and MTL. We extended a multi-task relationship learning \(^2\) model to deal with binary targets and applied it to drug repositioning problem. We also investigated whether imposing a prior to target relatedness could improve the performance of MTL predictions. In our problem, the prior knowledge comes from the hierarchical structure of ICD9 codes (i.e., disease areas and grouping information of the targets). In total, we considered three drug repositioning methods in the experiment: (1) STL; (2) MTL without prior; (3) MTL with prior. We used a 10-fold cross validation scheme to evaluate the performance of all methods.

Results

Figure 2 shows the ROC curves of the three methods in the experiment. The figure shows that MTL without prior and MTL with prior obtained AUC scores of 0.8431 and 0.8592 respectively, which are significantly higher than that of STL (0.7930). In our drug repositioning experiment, learning multiple related tasks simultaneously effectively increases the training sample (i.e., known drug-disease interactions) size for each task, and improves the prediction performance. Figure 2 also shows that incorporating a prior from ICD9 hierarchical structure could improve the performance of MTL predictions.

As an important by-product, MTLs also learn target relatedness (i.e., disease associations) during the predictions. Figure 3 is a heatmap of learned target relatedness from MTL with prior. In the heatmap, a high value between two tasks indicates the two diseases are highly correlated during the predictions. For example, ICD9 group 401 (Hypertension) is found to be highly correlated with ICD9 group 299 (Autism) by MTL with prior, which is in agreement with a recent clinical trial \(^3\). The learned target relatedness from MTL could provide additional insights for downstream investigations including clinical trials.
Discussion

To our knowledge, the MTL framework proposed in the study is the first feature-vector based multi-task learning method for drug repositioning hypothesis generation. Our preliminary results demonstrate that learning multiple related tasks simultaneously is effective in achieving improved performance. Furthermore, learned target relatedness from MTL could help to reveal MoA of drug repositioning hypotheses. In future work, we intend to integrate more features of drugs (e.g., targets, side effects) to the predictions, and to incorporate and compare more prior information (e.g., disease co-occurrence in real-world data) on initializing task relatedness.

\[
y \in \mathbb{R}^N, \quad X \in \mathbb{R}^{N \times D}, \quad w \in \mathbb{R}^D, \quad Y \in \mathbb{R}^{N \times S}, \quad X \in \mathbb{R}^{N \times D}, \quad W \in \mathbb{R}^{D \times S}
\]

(a) Single-task learning

(b) Multi-task learning

Identification of Venous Thromboembolism from Electronic Medical Records with Information Extraction

Shuai Zheng, PhD¹, Raymund Dantes MD, MPH¹, James J. Lu, PhD¹, Sheri Chernetsky Tejedor, MD¹, Michele Beckman, MPH², Asha Krishnaswamy, MSc², Lisa C. Richardson, MD², Fusheng Wang, PhD¹

¹ Emory University, Atlanta, GA
² Centers for Disease Control and Prevention, Atlanta, GA

Introduction:

Venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE), is associated with significant morbidity and mortality, resulting in approximately 100,000 deaths per year in the U.S [1]. VTE can be diagnosed by several radiologic studies, including lower or upper extremity ultrasonography and computerized tomography (CT) of the chest. Federally mandated reporting of VTE defined by the Agency for Healthcare Research and Quality Patient Safety Indicator 12 (AHRQ PSI-12) [2] is based on administrative and billing data, whose accuracy for detecting VTE has yet to be demonstrated. While automated information extraction (IE) from electronic medical records has high potential for improving VTE identification, existing tools either require large, manually annotated datasets for training, or considerable linguistic expertise for constructing domain specific rules. We present IDEAL-X [3], a novel open source IE system, and evaluate its accuracy for identifying VTE diagnosis directly from radiology reports in electronic medical records.

Methods:

Full text of radiology reports and clinical data were extracted from the electronic medical records (Cerner Corp, Kansas City, MO) of 13,248 patients admitted to Emory University Orthopedic and Spine Hospital from 2009-2014. Patient encounters were defined as a hospital admission where both surgery (of the spine, hip, or knee) and a radiology diagnostic study for VTE were performed. A physician manually reviewed each radiology report for diagnosis of a DVT or PE. The IDEAL-X system analyzed the same radiology report under two separate modes: i) controlled vocabulary mode, where the user specifies upfront terminology and contextual information (such as relevant and irrelevant report sections) to be extracted, and ii) online machine learning mode, where all terminology and contextual information is learned incrementally. The system processes a report and proposes VTE diagnostic values for a user to review. The user’s feedback (accepting or correcting system proposed values) provides linguistic features of the value extracted, which automatically update and improve the system’s extraction model for the next iteration. Performance was analyzed for total radiology reports, and patient encounters (multiple reports per encounter possible).

Results:

Among 2083 radiology reports in the testing dataset, IDEAL-X in controlled vocabulary mode correctly identified 176/181 VTE events, achieving a sensitivity of 97.2% (95% Confidence Interval [CI] 93.7-99.1%) and specificity of 99.3% (95% CI 98.9-99.7%) when compared to manual review (Table 1). This performance was superior to online machine learning mode, which achieved an overall sensitivity of 92% (95% CI 88.3%-96.1) and 99% specificity (95% CI 98.5%-99.4%), and required approximately 50% of reports to be processed before achieving >95% sensitivity and specificity (Figure 1). Among 422 surgical encounters with diagnostic radiographic studies for VTE, IDEAL-X in controlled vocabulary mode correctly identified 41/42 VTE events, achieving a sensitivity of 97.6% (95% CI 97.4-97.8%) and specificity of 99.8% (95% CI 98.7-100.0%) (Table 2). The performance surpasses that of AHRQ-PSI 12 [2], which has sensitivity of 92.9% (95% CI 80.5-98.4%) and specificity of 92.9% (95% CI 89.8-95.3%), though only the difference in specificity was statistically significant (p<0.01).

Discussion:

IDEAL-X is able to correctly identify VTE from the free text of radiology reports with very high sensitivity and specificity, surpassing the performance of identification based on AHRQ PSI-12. Clinical quality metrics sourced from clinical records may have increased validity compared to those from administrative data sources. Customized controlled vocabulary simplifies the deployment process, and is better suited for instances with low positive incidences, including VTE. Online machine learning enables a user to provide real-time feedback to continually improve the accuracy of extraction of subsequent reports. IDEAL-X’s workflow requires no linguistic expertise from the user, and can be easily adapted to different clinical applications to improve detection and surveillance of medical conditions. A comparative study of IDEAL-X against other natural language processing systems for DVT detection is beyond the space available here, and will be reported in the future.

Introduction

The electronic health record (EHR) with computerized provider order entry (CPOE) can provide the clinician with real-time guidance and support at the point of prescribing1. These systems have been shown to improve the safety and quality of patient care by, for example, reducing the likelihood of medication errors and consequent patient harm2. One of the basic drug interaction alert types is drug allergy checking. This provides the clinicians with an alert or a reminder if the patient has a documented allergy to the prescribed drug in their EHR. However, clinicians are often exposed to a high number of drug allergy interaction (DAI) alerts, which can result in them experiencing alert fatigue; Consequently, clinicians can ignore or override both clinically important and unimportant alerts3,4. Ignoring alerts can potentially lead to patient harm and other unintended consequences, thus many efforts are underway to improve the accuracy of the alerts and reduce alert fatigue5,6. Unfortunately, little is known about the acceptance rates and other aspects of DAI alerts presented to providers.

In this study, we aimed to: 1) evaluate providers’ DAI alert overrides over the last ten years (2004-2013); 2) examine the different types of reactions overridden and whether these related to definite, probable or possible drug-allergy matches; and 3) examine the reasons why providers chose to override these drug-allergy interaction alerts.

Methods

In this observational, cross sectional study, we assessed ten years of DAI alert records from two large academic medical centers (Brigham and Women's Hospital and Massachusetts General Hospital). Both hospitals are part of Partners Healthcare, an integrated healthcare system in the Boston area. Data were extracted from the Partners Enterprise-wide Allergy Repository (PEAR), a longitudinal allergy database shared within the Partners provider/hospital network7. We identified all DAI alerts (n=928,962) from the PEAR database between Jan 2004 and Dec 2013. We assessed the most commonly triggered DAI alerts with frequencies higher than 0.1% of total alerts, resulting in 611,192 records (65.8%) included in this analysis.

In PEAR, medications are stored and encoded using a combination of proprietary (First Databank, Inc.™) and local (Partners Master Drug Dictionary) terminologies. For patients admitted to the healthcare system, providers enter the patient’s allergy information in the EHR. The system then checks every prescribed medication against possible allergies in PEAR. Drug-allergy interaction alerts are triggered when a prescribed medication matches the stored allergy as either: Definite match (e.g., levofloxacin -> levofloxacin): where there is an exact match between the allergen and prescribed medication (or main medication ingredient); Probable match (e.g., ciprofloxacin -- > levofloxacin): where the prescribed medication matches the allergen group of the documented allergen; or Possible match (e.g., penicillin (penicillins) -- > cephalexin (cephalosporins): where the cross-sensitivity group of the patient’s allergen matches the cross-sensitivity group of the medication ingredient. Each alert warning lists one or more reactions that the patient is at risk of being exposed to (e.g., anaphylaxis). We reviewed the different types of reactions as well as the current literature8,9 and classified them into two main types: (1) Potentially immune mediated (e.g., rash or anaphylaxis) or non-immune mediated (e.g., nausea or vomiting), and (2) Potentially life threatening (e.g., anaphylaxis or bronchospasm) or non-life threatening (e.g., gastrointestinal upset or nausea).
**Results**

Overall, we found an increase in the rate of DAI alert overrides, from 83.3% in 2004 to 87.6% in 2013 (p<.001). The most common DAI alerts were triggered by allergies to narcotics (48%) and other analgesics (6%), antibiotics (10%) and statins (2%). Only slightly more than one-third (35.1%) of drugs overridden had reactions that were potentially immune mediated. Providers were least likely to override alerts for definite allergen and prescribed medication matches that resulted in an immune mediated (72.8%) and life threatening reactions (74.1%) as compared to possible (cross-sensitivity) or probable (allergen group) matches. Finally, more than half of the overrides reasons pointed to irrelevant alerts (i.e. Patient has tolerated the medication before, 50.9%) and providers were significantly more likely to override repeated alerts (89.7%) rather than first time alerts (77.4%, p < .001).

**Limitations**

Our data were confined to two large academic hospitals in Boston, which limits the generalizability of our findings. In addition, although based on the literature and expert panel discussions, our classification of potentially life threatening and potentially immune mediated reaction is an estimation based on the captured patient reactions rather than a conclusive statement based on patient lab/pathology or allergy tests.

**Conclusion**

We examined one of the largest reported allergy datasets for trends in the most commonly triggered drug allergy interaction alerts in the inpatient setting. The most common DAI alerts were triggered by allergies to narcotics and other analgesics, several antibiotic groups, and statins. Only slightly more than one-third of the reactions were potentially immune mediated. Over the past decade, we identified an alarming trend of increasing rate of DAI alert overrides, culminating in 87.6% in 2013. The DAI alert override rates were similarly high for both potentially immune mediated or life threatening reactions. Overall, definite allergy and prescribed medication matches were overridden less frequently compared to probable or possible matches. The most overridden medication groups were the narcotic analgesics and statins. Finally, more than half of the overrides reasons pointed to irrelevant alerts and providers were significantly more likely to override repeated alerts rather than first time alerts. Our findings underline the urgent need for more efforts focused on providing more accurate and relevant drug allergy interaction alerts for providers to decrease alert overrides and alert fatigue. Finally, further investigation is needed into providers’ reasons for overriding DAI alerts.

The sociotechnical perspective in biomedical informatics: what do we understand and measure?

Panelists
Jos Aarts, PhD, FACMI1, Joan Ash, PhD, FACMI2, Andre Kushniruk, PhD, FACMI3, Dean F. Sittig, PhD, FACMI4

Moderator
Jessica S. Ancker, MPH, PhD5

1State University of New York at Buffalo, NY; 2Oregon Health & Science University, Portland, OR; 3University of Victoria, Victoria, BC, Canada; 4The University of Texas Health Science Center, Houston, TX; 5Weill Cornell Medical College, New York, NY

Abstract
Sociotechnical theory has become accepted in the last fifteen years for understanding and evaluating the complexity of design and implementation of health information technology (HIT) in complex health care organizations. The IOM report on information technology and patient safety argues that safety is the product of the sociotechnical system and its constituent parts. The core concept of sociotechnical theory is interdependency. Sociotechnical theory raises a number of methodological questions, since it sits uneasy with accepted research paradigms in biomedicine that focus on measurable clinical outcomes research. The panel seeks to address the value of sociotechnical theory, the underlying research methodologies and to give practical guidance on how studies involving a sociotechnical perspective can be conducted and published.

Keywords:
Biomedical informatics; sociotechnical theory; interpretive research; research metrics; evaluation

Introduction
In its report ‘Health IT and Patient Safety’ the IOM Committee on Patient Safety and Health Information Technology writes that safety is the product of the larger sociotechnical system and emerges from the interaction between different parts of this larger system [1]. The committee defines a sociotechnical system as a collection of hardware and software working in concert within an organization that includes people, processes and technology. Berg, Aarts and van der Lei emphasize the role of the social sciences in understanding sociotechnical systems [2]. From this perspective health care work is a social ‘real life’ phenomenon, which may seem ‘messy’ at first, but is guided by a practical rationality that can be overlooked only at a high price (i.e. systems that compromise patient safety). Therefore, technological innovation is a social process that deeply affects organizations. Finally, through in-depth formative evaluation, system design and implementation can be improved. Klein makes the case that in sociotechnical theory interdependence is the most important concept, and more specifically interdependencies between social and technical aspects of the system (and not social and technical systems) [3].

A quick search of the terms ‘sociotechnical’ and ‘socio-technical’ in the journal title field in PubMed yields 151 publications. Seventeen publications date from before 2000, and 45 papers were published since 2011. This simply means that the term ‘sociotechnical’ is catching on in the health care literature, but does not necessarily imply a consensus on the use of this term.

The increasing perceived relevance of the concept raises a number of issues. First what does the concept mean? It is striking how the concept is used as an adjective: sociotechnical perspective, sociotechnical system, sociotechnical understanding, sociotechnical theory. What is the implication of the adjective for these concepts? What research methods are implied? It is clear that the sociotechnical concept sits uneasily with more accepted methodologies in biomedicine such as the randomized clinical trial. At the one end of the methodological spectrum researchers consider sociotechnical theory as an interpretive theory. It helps them to analyze the descriptions that they obtained through qualitative research methods, such as observing and interviewing. At the other end researchers try to decompose sociotechnical theory into domains, suggesting that each of these domains can be studied
independently. The next question is whether metrics (measurable quantities) can be developed to measure and assess the sociotechnical aspects of a system. These questions are relevant when information technology is embedded into complex health care systems.

This panel is cosponsored by the AMIA Evaluation (Eval) Working Group and People and Organizational Issues (POI) working group.

The panel

This panel seeks to address how researchers utilize sociotechnical thinking in their research projects. Questions that the panelists seek to address are:

• How do they use sociotechnical theory and methods?
• How complete is sociotechnical theory?
• Is sociotechnical understanding of HIT in need of metrics?
• How acceptable is theoretical diversity for health informatics?
• Does sociotechnical theory necessarily imply qualitative research methods?
• How studies involving a sociotechnical perspective be published?

The panelists

For this panel, participants will describe how the theoretical underpinnings of the sociotechnical approach can be applied to real-world, clinical informatics problems and how it has influenced their research methods.

Dr. Aarts’s studies of clinical decision support in electronic medication prescribing lead him to a number of questions about the difficulty of implementing CPOE in different settings. Basically, electronic prescribing based on evidence-based medicine collides with social values that prescribing represent. Understanding these values using sociotechnical theory is crucial to address the design and implementation of electronic prescribing systems [4]. In Dr. Aarts’s perspective sociotechnical theory is a qualitative interpretive theory.

Dr. Kushniruk will describe work in development of an integrative cognitive sociotechnical approach to the design, deployment and testing of health information systems that he co-developed with Dr. Elizabeth Borycki [5]. The approach seeks to integrate methods and frameworks from the study of human factors and cognitive science with socio-technical approaches to analyzing health information system use and impact. To illustrate this multi-faceted approach, examples from the evaluation of electronic health records and medication administration systems will be described. An in-situ approach to conducting clinical simulations that can identify both user and workflow issues that arise in complex health care settings will be described. Implications of the approach for the deployment of systems with increased system-organizational fit and decreased potential for inadvertently introducing technology-induced error will be discussed.

Dr. Sittig will describe an 8-dimension socio-technical model that he co-developed with Hardeep Singh. Briefly, this model and the resulting interactions between the various dimensions of the model has helped them explore and understand clinical informatics problems such as: management of abnormal laboratory test results, development of comparative effectiveness research platforms, and use of a service-oriented architecture approach to the provision of externally managed clinical decision support interventions [6].

Dr. Ash will discuss how this same 8-dimension model has been used in two different ways to expand our knowledge about the safety of electronic health record (EHR) systems. First, she will describe using the model as an organizing framework for synthesizing and interpreting literature published prior to 2010 about EHR safety to produce a white paper which provided the background information for the aforementioned Institute of Medicine study. Next, she will describe how the model informed the research behind the principles and practices recommended in the Safety Assurance Factors for EHR Safety (SAFER) guides developed for the Office of the National Coordinator for Health Information Technology [7].

Following the panelist’s presentations, the moderator will start the discussion by asking a few questions to help the audience understand the similarities and differences among the various approaches. We will then open the floor for a free-ranging discussion of all aspects of the sociotechnical approach.
Learning objectives

After participating in the session, the attendant should be able to:

• Describe how sociotechnical theory can be used in biomedical informatics research.
• Identify in which research project it is appropriate to use sociotechnical theory.
• Understand how to publish studies using sociotechnical theory in biomedical informatics journals.
• Articulate a sociotechnical research agenda for biomedical informatics related to HIT design and implementation.

Conflict of interest

The participants have no conflict of interest to declare.

Abstract

Computational drug repositioning is a promising and efficient tool for discovering new uses from existing drugs and holds the great potential for precision medicine in the age of big data. The explosive growth of large-scale genomic and phenotypic data, as well data of small molecular compounds with granted regulatory approval, is enabling new developments for computational repositioning. To achieve the shortest path towards new drug indications, advanced data processing and analysis strategies are critical for making sense of these heterogeneous molecular measurements. Despite the progress simulated by big data analytics, there is clearly room for technical improvement with regard to computational drug reppositioning methods. Furthermore, to materialize the true potential and impact of these methods, much work is needed to show that they can be successfully adopted into practical applications. In this panel, participants will summarize the recent advances in computational drug repositioning and identify challenges and opportunities. Panel participants will synthesize their perspectives on these key issues and likely future developments in this area, explore a diverse set of topics, and engage in thoughtful discussion with the audience.

Learning Objectives

After participating in this session, the learner should be better able to:

- Recognize the benefits of applying computational methods for drug repositioning hypothesis generation
- Compare genomic, phenotypic, clinical, epidemiological data, and their contributions to computational methods
- Understand recent advances, challenges, and opportunities of computational drug repositioning
- Evaluate computational repositioning methods from a real-world perspective
- Validate drug repositioning hypotheses in a systematic manner

Introduction

The inefficiency of pharmaceutical drug development with high expenditure but low productivity has been widely discussed. Drug repositioning, the process of finding additional indications (i.e., diseases) for existing drugs, presents a promising avenue for identifying better and safer treatments without the full cost or time required for de novo drug development. Candidates for repositioning are usually either market drugs or drugs that have been
discontinued in clinical trials for reasons other than safety concerns. Because the safety profiles of these drugs are known, clinical trials for alternative indications are cheaper, potentially faster and carry less risk than de novo drug development. Any newly identified indications can be quickly evaluated from phase II clinical trials. Drug repositioning can reduce drug discovery and development time from 10-17 years to potentially 3-12 years. Therefore, it is not surprising that in recent years, new indications, new formulations, and new combinations of previously marketed products accounted for more than 30% of the new medicines that reach their first markets.

Drug repositioning has drawn widespread attention from the pharmaceutical industry, government agencies, and academic institutes. For example, The United States National Center for Advancing Translational Sciences (NCATS) is partnering with pharmaceutical companies to offer funding for repositioning. US Food and Drug Administration (FDA) is also enabling drug repositioning, with the creation of several public databases specifically for computational drug repositioning. All of these efforts significantly promoted drug repositioning research.

**Urgency, Timeliness and Importance of the Panel**

Big data analytics for both drugs and diseases provide an unprecedented opportunity to uncover novel statistical associations between drugs and diseases in a scalable manner. With the attention on translational research in recent years, a new set of computational methods are being developed which examine drug-disease associations and drug off-target effects through system and network approaches. These new approaches take advantage of the unprecedented large-scale high-throughput measurements, such as drug chemical structures and screens, side effect profiles, transcriptional responses after drug treatment, genome wide association studies, and combined knowledge. More importantly there are increasing reports of these findings being validated in experimental models and clinical observations, thus clarifying the value proposition for computational drug discovery. As a result, now is an exciting time for computational scientists to gain evidence for reusing an existing drug for a different use or generate testable hypotheses for further screening.

Despite the progress, there is clearly room for technical improvement with regard to computational drug repositioning approaches. Furthermore, to materialize the true potential and impact of these methods, much work is needed to show that they can be successfully adopted into practical applications. Current challenges include: (1) the transformation of theoretical computational models into practical use if far from straightforward, due to some inevitable factors like missing data, data bias, and technical limitations of computational methods; (2) the lack of structured gold standard (other than cross-validation) for drug repositioning makes it hard to compare and evaluate the performance of computational methods; (3) the standard quantitative measurements in machine learning (e.g., AUC, AUPR, F-score) have their limitations to evaluate computational drug repositioning methods. For example, in real-world drug discovery, a desired method should provide relatively high confidence that the first few indications that are predicted for a drug contain at least one that will be validated in clinical trials and make a positive impact on patients (otherwise the project will be terminated); (4) the lack of standard models for repositioning hypotheses validation (i.e., if one comes up a hypotheses of drug A could potentially treat disease B, how can she/he find the best model to validate this hypothesis) hinders the impact of computational methods in the real-world settings. Therefore, it is very urgent to bring the challenges and opportunities to the table. The aim of our panel session is to provide a forum to bring together the research community for a serious examination of these important issues and to stimulate innovative work for years to come.

This panel gathers five researchers who actively design, develop, and/or validate computational drug repositioning methods. The five panel participants have diverse backgrounds (e.g., academia and industry, MBBS/MD and PhD, big data and biomedicine) and have their own perspectives on these challenges and opportunities. All participants will share experiences in conducting their research in computational drug repositioning and discuss the implications of their studies. These individual stories will then serve as the material for an open discussion with the audience. In sum, this is an important panel to have at AMIA in order to engage the community in discussing critical questions about advancing computational drug repositioning, which shortens the drug development timeline and gets new treatments to patients faster.

**Brief Description of Panelists and Presentations**

The panel session will begin with four 10-minute presentations of panelists (each followed by 5 minutes of questions) detailing experiences, approaches and outcomes of their exemplar studies. Then we will open the floor to discussion among panelists and with the audience in the remaining 30 minutes.

**Atul Butte, MD, PhD** is the new Director of the new Institute of Computational Health Sciences (ICHS) at the University of California, San Francisco, and a Professor of Pediatrics. Dr. Butte will present his experience in
translating trillions points of data into new uses for drugs. Dr. Butte's lab builds and applies tools that convert trillions points of molecular, clinical, and epidemiological data -- measured by researchers and clinicians over the past decade and now commonly termed “big data” -- into diagnostics, therapeutics, and new insights into disease. He will highlight how publicly available molecular measurements to find new uses for drugs including drug repositioning for inflammatory bowel disease, as well as discovering new treatable inflammatory mechanisms of disease in type 2 diabetes, and how the next generation of biotech companies might even start in your garage.

Nigam Shah, MBBS, PhD is Assistant Professor of Medicine (Biomedical Informatics) at Stanford University, Assistant Director of the Center for Biomedical Informatics Research, and a core member of the Biomedical Informatics Graduate Program. Dr. Shah will present his recent work on automated detection of off-label drug use, which is a form of drug repositioning because such uses have not been evaluated for safety and efficacy. He will describe a data-mining approach for systematically identifying off-label usages using features derived from free text clinical notes and features extracted from two databases on known usage (Medi-Span and DrugBank).

Nicholas Tatonetti, PhD is Assistant Professor of Biomedical Informatics in the Departments of Biomedical Informatics, Systems Biology, and Medicine and is Director of Clinical Informatics at the Herbert Irving Comprehensive Cancer Center at Columbia University. Dr. Tatonetti will speak about network medicine, which integrates experimental data on gene, protein, and metabolic interactions with clinical knowledge of disease and pharmacology in order to extend the understanding of diseases and their treatments. He will highlight a case study that uses network analysis and graph theory for understanding drug safety and efficacy, which recently published in Clinical Pharmacology & Therapeutics.

Hua Xu, PhD is Robert H. Graham Associate Professor at the School of Biomedical Informatics in The University of Texas Health Science Center at Houston (UTHealth). He directs the Center for Computational Biomedicine at UTHealth. Dr. Xu will present his recent work to assess the feasibility of using electronic health records (EHRs) and automated informatics methods to efficiently validate a recent drug repurposing association of metformin reducing cancer mortality. This study serves as a model for robust and inexpensive validation studies for drug repurposing signals using EHR data.

Ping Zhang, PhD is Research Staff Member in IBM T. J. Watson Research Center. Dr. Zhang will moderate the panel. During the panel discussion, Dr. Zhang will discuss how to evaluate and validate drug repositioning methods in real-world settings.

Discussion Questions
A list of discussion questions to enhance audience participation:

1. How will computational methods accelerate drug repositioning (or even drug development in general) efforts?
2. Lots of data are used for drug repositioning, e.g., genomic, phenotypic, clinical, epidemiological data. What are the pros and cons for each type of data?
3. How to integrate disparate sources of data for drug repositioning purpose? Is there any prior weight for each data source?
4. What is the success rate of drug repositioning methods in a real-world setting? How much improvement after using computational methods? How to transfer computational models into practical uses?
5. How to design an experiment to compare multiple computational methods for a repositioning purpose? How to prepare/define gold standard? Which evaluation metrics should choose? Do current metrics meet the needs from pharmaceutical industry?
6. How to validate repositioning candidates? How to identify a best model for a specific hypotheses validation? What are the pros and cons for literature/experimental/clinical validations? How to leverage real-world data to validate repositioning candidates?

Participation Statement
All proposed participants have agreed to take part on the panel.
Health Data from Wearables:
Clinical Implications of the Quantified Self

Mobile Health Track

Panel Organizer and Participants
Emil Chiauzzi, Ph.D. (organizer and presenter)
Research Director
PatientsLikeMe
Cambridge, MA

Kevin Patrick, M.D., M.S. (moderator and presenter)
Professor of Family Medicine & Public Health
Director, Center for Wireless and Population Health Systems, The Qualcomm Institute
University of California, San Diego
San Diego, CA

Cinnamon Bloss, Ph.D. (presenter)
Assistant Professor, Departments of Psychiatry and Family Medicine & Public Health, Division of Health Policy
University of California, San Diego
San Diego, CA

Ernesto Ramirez (presenter)
Program Director
Quantified Self Labs
San Diego, CA

All four original panel members have agreed to participate in the panel. We will add a patient to the panel prior to the conference.

Abstract
The popularity of health self-tracking through the use of consumer health devices has primarily been confined to fitness and wellness contexts, but there has been increasing interest in leveraging this health data in clinical decision-making and care delivery. Because personal tracking devices provide a glimpse into the everyday behavior of patients, there is potentially great value in integrating this data with traditional medical data. Such integration may be particularly useful with patients experiencing chronic diseases, as their conditions require daily self-management that include activity goals, sleep monitoring, an understanding of calorie expenditure, and tracking of medication adherence. However, there are many questions that are unresolved. There is a need for clarity about how such data can be utilized in clinical encounters. There are numerous devices available to consumers and they vary greatly in features and data quality. The patient perspective has not been fully leveraged, as devices generally target a fitness market. Users of tracking devices may not be fully cognizant of issues around privacy, data sharing, and data control. Most importantly, does the use of self-tracking devices affect disease outcomes?

Description of Panel
This panel will examine personal health data from several perspectives; (1) the use of data by clinicians, (2) the validity of wearable data and the potential capabilities of wearables going forward, (3) patient perspectives on the use of wearables in disease self-management, and (4) ethical and privacy issues in the use and transmission of this data.

Kevin Patrick (Moderator)
Personal health data promises to greatly enhance how clinicians manage their patients’ conditions. Instead of relying on periodic self-reports of behaviors or symptoms, data accumulated on a 24x7 basis from wearable and wireless technologies can be summarized and reviewed. Analysis of patterns in these data can be used to infer trajectories of illness and health and aid in developing just-in-time adaptive interventions that might prevent deterioration in health status. However, many challenges exist with respect to factoring personal health data into the workflow of busy
clinicians. This presentation will provide an overview of these issues.

**Ernesto Ramirez**
Self-tracking data are becoming a part of the normal course of everyday life for millions of individuals around the world. What are some of the ways they are using that data to understand themselves and their health? We will highlight the unique and innovative methods and insights being discovered and discussed at Quantified Self meetings and events worldwide. Particular focus will be given to personal data access and its role in exposing up new knowledge generation methods for personal and public benefit. Additionally, we’ll discuss issues with data validity and reliability regarding consumer sensing technologies.

**Emil Chiauzzi**
The use of wearables has allowed patients with chronic diseases to take an active role in self-management. This presentation will review insights from a series of pilot studies conducted with members of PatientsLikeMe, an online patient research network. This presentation will review the ways in which patients have integrated wearable use into their treatment, as well as their perspectives on behavior change methods that can be integrated with wearable use. The importance of engagement strategies will also be highlighted.

**Cinnamon Bloss**
Personal health data that circulate outside the mainstream of traditional health care have the potential to be used in ways that could improve health, in part, by empowering individuals to take greater control over their own health. In sharp contrast to the idea of individual empowerment around health, however, is a personal health data ecosystem in which individuals may feel they have little control over the flow of their personal information and thus privacy. This presentation will discuss issues related to personal conceptions of privacy and health data ownership. Preliminary data on individuals’ perceptions and expectations of privacy in the context of different personal health data technologies will be presented.

**Patient Presenter (TBD)**
The use of wearables to manage chronic disease offers a different set of challenges than using these devices for personal fitness. The fluctuations in symptoms, physical limitations, effects of pain, and other factors change the ways in which a wearables device is used on a daily basis. Many patients find unique ways to integrate these devices (and their data) into self-management. The limitations and advantages of these devices in a chronic disease context will be discussed.

**Explanation of Topic**
The explosion of consumer health devices, punctuated by the publicity surrounding devices such as the Apple Watch, makes this a very timely topic. There is a growing research and clinical literature on the application of wearables beyond fitness contexts to clinical contexts. At the same time there are a variety of technological and practice barriers that need to be addressed. This panel seems best geared for audience that is composed of clinicians, researchers, and informaticists who are curious about how this data can be maximized in their work.

**Discussion Questions**
What is the role of wearable data in medical care?
How can wearable data best be integrated into the clinical workflow?
How do patients perceive the usefulness of devices in their disease self-management?
What clinical assessment needs can personal health data best address?
What is the potential for wearable use to affect health outcomes?
What adaptations must patients make to use wearables effectively?
What are key privacy concerns in the use of wearable data?
The Informatics Workforce for Population Health: Challenges, Initiatives and the Path Forward

Brian E. Dixon, MPA, PhD1,2, Marty LaVenture, PhD, MPH3, Bill Brand, MPH4, Arthur Davidson, MD, MSPH5, Shaun J. Grannis, MD, MS2,6
1IU Richard M. Fairbanks School of Public Health, Indianapolis, IN; 2Regenstrief Institute Center for Biomedical Informatics, Indianapolis, IN; 3Minnesota Department of Health, St. Paul, MN; 4Public Health Informatics Institute, Decatur, GA; 5Denver Public Health, Denver, CO; 6Indiana University School of Medicine, Indianapolis, IN

Abstract
Public health informatics (PHI) makes significant contributions to detecting, monitoring and improving population health. Although PHI professionals exist in local, state and federal public health agencies, we know little about them or their needs. Yet there exist several disparate education and training programs in PHI that seek to prepare the public health workforce for designing, implementing, and using PHI systems. This panel presents diverse views on the PHI workforce and its needs from local, state, federal and international levels. Current data on the characteristics and information needs of the PHI workforce will be presented. Then panelists will discuss the various initiatives and programs that seek to educate or train the PHI workforce. The panel will raise questions and discuss opportunities about how to better organize information about training opportunities and the role that AMIA should play in supporting the existing and future PHI workforce.

Introduction and Background
Public health informatics (PHI) is the systematic application of information and computer science as well as information systems to public health practice, research, and learning (1). Although public health practitioners have long utilized information technologies to perform their jobs, the growth of PHI as a discipline within both public health and the broader field of informatics accelerated at the start of the twenty-first century.

During the first decade, PHI activities were characterized by a focus on the core public health function of monitoring populations: early detection of bioterrorism, such as the Anthrax attacks in the U.S. (2) and the Tokyo subway attacks (3), as well as global health threats such as SARS (4) and the H1N1 pandemic (5). While the threat of a large-scale epidemic has not diminished in recent years, as evidenced in 2014 by MERS (6, 7) and Ebola (8), changes in national policies and funding priorities have steered PHI in new directions (9). Today PHI not only supports core public health functions, but PHI contributes to the following activities in support of population health and strengthening the public health infrastructure: 1) implementation of electronic health record (EHR) systems and health information exchange (HIE) to enable successful achievement of “meaningful use” criteria such as electronic reporting of notifiable diseases; 2) measurement of a wider array of health indicators, including social determinants of health through “big data” analysis of multiple community data sources; and 3) development, implementation, and assessment of patient-centered technologies aimed at supporting health and well-being in the changing landscape of health care delivery locations such as the patient’s home, community organizations, and pharmacy.

Systematic downsizing of public health departments across the United States over the past decade (10, 11) has created the need for an estimated 250,000 workers by 2020 to maintain current capacity for public health services (12). Today, given the growing demand for a PHI capable workforce, key stakeholders recognize PHI as an important core within modern public health practice (13-15). Yet only a fraction of the public health workforce is estimated to have received informatics training or specialization in PHI, and we know little about the characteristics (e.g., race, age) or information needs (e.g., competency skill level) of current PHI workers.

Panel Description
This panel will review the state of the existing PHI workforce, discuss the challenges in cultivating a robust workforce, and brief the audience on existing initiatives aimed at preparing the next generation of PHI leaders. Each panelist brings a unique perspective and contribution to the common theme of strengthening the PHI workforce. Together they will provide views from research, education and operations/practice. Attendees will leave with a sense of where things stand as well as directions the field is headed to mitigate the need for a highly trained PHI workforce. Given that AMIA strives to be the professional home for PHI, it is well suited for the annual conference.
Current State of the PHI Workforce (Dixon)

The panel will begin with a brief review of the existing state of the PHI workforce by Brian E. Dixon, PhD. Dr. Dixon is a research scientist at the Regenstrief Institute and faculty at the Indiana University Fairbanks School of Public Health. He further serves on the Executive Committee of the PHI Working Group within AMIA.

While organizations such as the National Association of City and County Health Officials (NACCHO) and the Association of State and Territorial Health Officers (ASTHO) gather data on the public health workforce, they have not comprehensively examined the PHI segment. Currently Dr. Dixon is leading a team of researchers to analyze the Public Health Workforce Information Needs Survey (PH WINS) conducted by ASTHO in late 2014. They survey includes responses from over 10,000 public health workers in state health agencies. Just 1.3% of the respondents indicated they work in a PHI role within their agency. In his presentation, Dr. Dixon will describe the survey and characterize the population of PHI respondents. He will further describe their information needs, and he will compare/contrast the ASTHO results with data from other workforce surveys. Relevant data from prior studies will also be presented as needed. The goal is to provide attendees with up-to-date information on the workforce and its unique information needs.

Existing Education and Training Efforts: View from the National Level (Brand)

Bill Brand is the Director of Informatics Science at the Public Health Informatics Institute (PHII) in Decatur Georgia. Mr. Brand will review several examples of PHI training programs, both for emerging PHI professionals and for public health practitioners who realize that PHI knowledge and skills are critical to being effective in their jobs. The review will include ONC certificate programs, various CDC fellowships, the PHII Informatics Academy, and the PHII Immunization Registry Workforce Development project. He will describe these projects, their aims, and how they contribute to the overall workforce development.

Initiatives and Views from the State Level (LaVenture)

Dr. Marty LaVenture heads the Office of Health Information Technology at the Minnesota Department of Health and leads the Minnesota e-Health Initiative. Dr. LaVenture will discuss the PHI workforce from a state health agency perspective. Specifically, he will discuss the status an ASTHO state public health informatics directors initiative to promote informatics roles and career series for public health informaticians. Furthermore, Dr. LaVenture currently represents the public health community on AMIA’s Advanced Interprofessional Informatics Certification (AIIC) Program steering committee, so he will provide a brief update on that initiative. In addition, he will discuss achieving balance between academic learning and immediate PHI training needs. He will further discuss opportunities for graduate student practicums and other project-based work to contribute to the overall development of the PHI workforce as part of achieving an informatics savvy organization. (16)

View from the Local Level (Davidson)

Art Davidson, MD is Director of Informatics, Epidemiology and Preparedness at Denver Public Health, Denver Health. Dr. Davidson will describe the informatics workforce needs and challenges within the Denver Metro region and nationally based on efforts and concerns from National Association of County and City Health Officials (NACCHO) colleagues. Dr. Davidson serves as co-chair for the interim executive committee of the ASTHO-housed, Public Health Community Platform – a multi-year CDC-funded initiative to support a community-driven, valued service. Particular local public health agency challenges to be addressed will include ability to develop local applications despite a constrained informatics workforce, key skills for application development, and strategic efforts around regional or national platforms. Issues of organizational role, recruitment, promotion and retention of skilled informaticians within a local health department will be discussed.

A View of the PHI Workforce from the International Level (Grannis)

Outside the U.S., PHI is commonly performed in the context of a Ministry of Health, which not only supports governmental public health functionality, but also serves as the administrator for the country’s health system. In this presentation, Dr. Shaun Grannis, Associate Professor of Family Medicine at the Indiana University School of Medicine and Associate Director of the Regenstrief Institute’s Center for Biomedical Informatics, will draw parallels between PHI and clinical informatics in the context of global health informatics activities. The capacity development needs (and efforts) for global health informatics will be compared to the activities of Ministries to illustrate how such efforts are complementary to emerging U.S. strategies for local, state, and federal governmental health agencies.
Discussion Questions

1. How should AMIA best support the growth and maintenance of the PHI workforce?
2. What is the role for AMIA in contributing to the content of PHI training programs?
3. How can AMIA support a better coordinated approach to collecting and disseminating information about PHI training programs and opportunities?
4. What role should AMIA play in certifying core competencies for those who choose to specialize in PHI?

Panel Organizer Statement

All participants have agreed to take part in the panel and discuss the topics as outlined above.

Abstract

Over the past decade, the disciplines of public health and global health informatics have rapidly expanded and continue to evolve within the field of biomedical informatics. Increased attention and activity by the U.S. Centers for Disease Control and Prevention as well as many health ministries, the World Health Organization, and non-governmental organizations are generating new knowledge and lessons regarding the development, implementation, and use of information systems in health care delivery around the globe. Thus, a growing body of literature now contains important insights and lessons from international informatics activities, stimulating the need to synthesize the knowledge for the field. In this panel, a review of recent literature in the areas of public health and global health informatics will be presented. Key articles revealing trends, methods, and lessons will be summarized to bring attendees up-to-date on the use of informatics to improve population health as well as care in low resource settings.

Introduction

At the AMIA 2013 and 2014 Annual Symposia, Drs. Brian Dixon and Jamie Pina presented well-attended panel presentations focused on summarizing recent literature and key activities in Public Health Informatics (PHI) and Global Health Informatics (GHI). We seek to present a similar panel at the 2015 symposium. Our goal is to provide a concise overview of landmark papers in PHI and GHI for the year prior to the 2015 symposium using the methods described below and to highlight key activities that have impacted PHI and GHI practice and research in the past 12 months. Furthermore, like the last two years, we will provide the output of our efforts as working documents available online enabling attendees, as well as those who cannot attend, to leverage our work throughout the year.

Overview

The fields of public and global health informatics are expanding. In 2012, the PHI Fellowship Program administered by the U.S. Centers for Disease Control and Prevention (CDC) became a Department of Labor Registered Apprenticeship. PHI was also one of the six sub-disciplines of informatics specified in the ONC certificate programs funded between 2010 and 2013. As a result, publications in PHI have dramatically increased. This is evidenced by an increase in \textit{Journal of the American Medical Informatics Association} (\textit{JAMIA}) PHI articles, as well as the emergence of a journal dedicated completed to the study and practice of PHI, the \textit{Online Journal of Public Health Informatics} (www.ojphi.org). Similar increases in programs and publications have been observed in the field of GHI. For example, Fogerty International fellowships now bring scholars from low-income counties to the U.S. for biomedical informatics training. The CDC also promotes a Global Public Health Informatics Program (http://www.cdc.gov/globalhealth/dphswd/gphip/what/objectives.htm) to build capacity and sustainability of health information systems world-wide. The impact factor and quality of publications in the \textit{International Journal of
Medical Informatics (IJMI) has also increased, leading to a significantly larger number of important papers published by non-U.S. scholars in informatics (1).

Given recent and continuing advances in PHI and GHI as well as the organizational resources committed by AMIA to the PHI and GHI Working Groups as well as its International Affairs Committee, an annual review of landmark publications in these sub-disciplines within the field of biomedical informatics is appropriate for the AMIA Annual Symposium. Two panelists (BED and JP) will each present a concise bibliography of recent landmark publications in either PHI or GHI. The session will be divided equally between PHI and GHI. A summary examining the convergence, synergies, priorities and possible future cooperation will be presented by the third panelist (JR). Time will be reserved at the end for discussion, question, and comments with the audience.

Methods

The methods used to select the literature in each part of the session are adapted from the work of the previous AMIA Year in Review sessions. Our search methodology to identify potentially high impact literature in PHI and GHI is outlined below. The methods will be executed using MEDLINE and selected resources not currently indexed such as the conference proceedings of the International Society for Disease Surveillance. Recommendations will also be solicited from the AMIA PHI and GHI working groups as well as International Affairs Committee members.

Candidate articles will be reviewed on a quarterly basis by a committee of experts in PHI and GHI, including Drs. Dixon, Turner, Kharrazi, Pina, and Richards, the Review’s core team members. Additional input from the AMIA PHI and GHI working groups will be solicited. Selected articles from the list of candidates will be determined through consensus discussions on quarterly conference calls. Final lists of selected articles will be made available online for reference following the symposium.

Public Health Informatics

In 2013 and 2014 to identify articles in PHI, we used the following query (customized for MEDLINE):

“Public Health Informatics”[mh] OR (“exp Public Health”[mh] and “exp Informatics”[mh]) OR (“public health”[mp] and “informatics”[mp])

This query in 2013 returned 392 results, after specific inclusion and exclusion criteria were applied 65 articles were fully reviewed. In 2014 the query returned 160 results, with 20 articles meeting the criteria for full review. While this query yielded a reasonable set for the committee to review and discuss within a short timeframe, the group feels the query is not sensitive enough to capture “information system” articles that fail to use the term “informatics.” Therefore we propose using the following query for 2015:

“Public Health Informatics”[mh] OR (“exp Public Health”[mh] and “exp Informatics”[mh]) OR (“public health”[mp] and “informatics”[mp]) OR (“public health”[mp] and “information system”[mp]) OR (“public health”[mp] and “information technology”[mp]) OR (“public health”[mp] and “electronic health record”[mh])

In the 2015 presentation, Dr. Dixon will present the final selection of papers from the set of PHI candidate papers. Papers may be further categorized into themes, such as disease surveillance, population health, public health decision support, or chronic disease management depending on the list of candidate papers and the perspectives of the review committee. When reviewing the papers, Dr. Dixon will briefly describe their aim, methods, and key findings. Paper results will also be discussed in the context of larger PHI developments, such as the release (or study) of a specific system (e.g., Biosense 2.0) or change in public health infrastructure (e.g., re-organization of the CDC’s division responsible for PHI). Context will help audience members connect specific study findings with larger trends within the biomedical informatics field of study and practice.

Global Health Informatics

In 2013 to identify articles in GHI, we used the following query (customized for MEDLINE):

(“exp Informatics”[mh] OR “exp Telemedicine”[mh] OR “information system”[mp]) AND (“Developing Countries”[mh] OR global OR ministry OR “low resource” or “resource-limited”[mp])

This query with a search range of 24 months returned 442 results. During the review process the GHI reviewers thought this query missed many known articles. To overcome these limitations, we worked closely with an information specialist at the CDC Library to develop this more sensitive query for our 2014 MEDLINE search:
This query with a search range of 12 months (11/01/2013-10/31/2014) returned 819 results. After a title and abstract review based on seven inclusion criteria, 199 articles were included in the final analysis. For 2015, we plan to further refine this search string to maintain sensitivity while increasing specificity to reduce non-GHI articles for final analysis.

In the 2015 presentation, Dr. Pina will present the final selection of papers from the set of GHI candidate papers. Papers may be further categorized into themes, such as mHealth, infrastructure, evaluation, capacity development, system implementation, etc. depending on candidate papers located and the review committee’s assessments. The reviewers will briefly describe the paper’s aim, methods, and key findings. Findings from the trends in the papers reviewed will also be discussed in context of global health or global informatics policy related activities, such as World Health Organization (WHO) guidelines, the US Congress reauthorization of the President’s Emergency Plan For AIDs Relief (PEPFAR) and the increasing number of individual country eHealth Strategy Policy documents.

Following the PHI and GHI presentations, Dr. Richards will provide a summary to examine findings to provide context for possible PHI and GHI priority activities for the coming year. The session will end with discussion. Our experience from last two years of presenting our findings has demonstrated that these related but unique sub-fields within biomedical informatics generate many interesting questions and comments from the audience and facilitate a dialogue between AMIA’s international and domestic membership.

Discussion Questions

We will draw from the following discussion questions to engage audience participation:

- We found several interesting trends in knowledge generation within PHI & GHI over the past year. Which trend(s) were surprising to you?
- Projecting on what we have found, what do you think will be the biggest trend for 2016?
- What trends do you know of in GHI and PHI for the past year that may not have made it into the literature, yet?
- What initiatives, organizations and/or funding may exist to drive improvements in PHI & GHI research methods as well as dissemination and translation into practice?
- How can AMIA, especially the PHI & GHI working groups, better support the generation of new knowledge for research and practice in our respective disciplines?

Panel Organizer Statement

All participants have agreed to take part in the panel and discuss the topics as outlined above.

Building an Open, Global Research Collaboratory: Lessons from the OHDSI Initiative

Jon D. Duke, MD MS¹, George Hripcsak, MD MS², Patrick Ryan PhD³, Nigam Shah MBBS, PhD⁴
¹Regenstrief Institute, Indianapolis, IN; ²Columbia University, New York, NY; ³Janssen Research and Development, Titusville, NJ; ⁴Stanford University, Palo Alto, CA

Abstract

The Observational Health Data Sciences and Informatics collaborative (OHDSI, pronounced ‘Odyssey’) was formed in 2013 with the goal of creating reliable scientific evidence through large-scale analysis of observational health data from around the world. To advance this goal, OHDSI has had to grow rapidly its scientific, technical, and community infrastructure. OHDSI has now grown to over 120 participants from 10 countries. Across the collaborative, there are over 50 databases covering hundreds of millions of patient lives. OHDSI has conducted multiple international network-based observational research studies using this infrastructure. In this panel, we present initial results and lessons learned from the OHDSI initiative.

Organizer: Jon D. Duke, MD, MS

Background and Panel Description

The Observational Health Data Sciences and Informatics collaborative (OHDSI, pronounced ‘Odyssey’) was formed in 2013 with the goal of creating reliable scientific evidence through large-scale analysis of observational health data from around the world. To advance this goal, OHDSI has had to grow rapidly its scientific, technical, and community infrastructure. OHDSI has now grown to over 120 participants from 10 countries. Across the collaborative, there are over 50 databases covering hundreds of millions of patient lives that have been transformed into a common data model. OHDSI has conducted multiple international network-based observational research studies using this infrastructure. In this panel, we present initial results and lessons learned from the OHDSI initiative.

Specifically, we will demonstrate how an international distributed network can be used to generate clinically meaningful results from disparate observational databases, using a systematic evaluation of the heterogeneity in patient treatment progression and its relation to current clinical guidelines as a motivating example. Areas of discussion will include technical challenges, such as accommodating diverse data sources, as well as social challenges, such as coordinating activities amongst diverse stakeholders with differing objectives including those in healthcare, academia, government, and industry. We will also explore the many rewards of a large international collaborative, including the sharing of expertise and the ability to execute multi-site research studies in a streamlined fashion.

By the end of this panel, attendees will gain an understanding of the issues and approaches to collaborative observational research.

Panel Importance and Target Audience

The proposed panel demonstrates the potential for international collaborative research and addresses the critical need for both institutional and individual stakeholders to leverage the rapid advances in collaborative data science. This panel will provide attendees with insight into the opportunities and challenges of an open research collaborative as well as a clear path to engaging in such initiatives. The target audience includes health informaticians, clinical and health services researchers, health IT leaders (e.g., CMIOs), implementation scientists, epidemiologists, biostatisticians, and data scientists.
Presentations

Vision for Research Studies in an Open Observational Research Network (G. Hripcsak)
The mission of OHDSI is to generate high quality medical evidence through large-scale observational research. Dr. Hripcsak will describe the scope of OHDSI and the vision for the kinds of research that may be supported and the current and planned mechanisms to facilitate such research. He will introduce a proof-of-concept study on treatment pathways to characterize the diversity of initial treatment pathways for three chronic diseases: Hypertension, Type II Diabetes, and Depression. While numerous treatment guidelines exist for chronic conditions, there is a paucity of data on the real-world treatment pathways that patients experience in practice.

Proof of Concept: a Large-Scale Study of Treatment Pathways (N. Shah)
Dr. Shah will describe the methods and results from the treatment pathways study. He will summarize the treatment pathways observed among patients who have at least 12 months of continuous observation and ongoing treatment following drug initiation. He will describe temporal trends, and characterize variations in treatment pathways by population, geography, and data capture process. Figure 1 shows a visualization of results from the hypertension pathways study.

Architecting a Common Data Model for Large-Scale Analytics (P. Ryan)
OHDSI utilizes the OMOP Common Data Model (CDM). First developed in 2008, the CDM was designed to enable standardized analysis of patient-level observational data to produce population-level real-world evidence from across multiple disparate data sources. Over 50 papers have been published using the CDM as a data model. Dr. Ryan will cover the design of the CDM and its standardized vocabularies as well as its evolution from supporting a pharmacovigilance methods research project to becoming a broader framework for collaborative research in healthcare. He will discuss how the architecture benefited the treatment pathways study, and he will discuss the challenges encountered when executing the study, primarily due to residuals differences among sites.

Transforming Data to the OMOP Model: Tools and Strategies for Data Owners (J. Duke)
For organizations wanting to participate in the OHDSI research network, transforming their data into the OMOP CDM is a necessary first step. Converting data from a complex existing source, such as an EHR, requires careful planning and the involvement of several key stakeholders (experts in the local source data, clinicians, developers) as well as support from the OHDSI community. In this presentation, Dr. Duke will discuss strategies for the OMOP ETL process as well as some specific software tools and community resources to aid in data transformation. He will then discuss an OHDSI software package known as ACHILLES (www.ohdsi.org/web/achilles), designed to assist with dataset characterization, quality assessment, and exploration of newly converted CDM data (Figure 2).
Figure 2. A screenshot of the ACHILLES data characterization and quality tool, assessing data density over time.

Discussion Questions

- What are the main challenges associated with distributed research?
- What are the costs and privacy risks of participating in a large network research?
- How do we know when to trust (or not trust) the results of a distributed study?
- What is gained and what is lost in the process of standardizing data to a common data model?
- How can standardized analytics be applied in a distributed network using a common data model?
- What are the domain and technical skillsets needed for transforming datasets from one model to another?
- How can the quality of a transformed data set be evaluated and, where necessary, improved?

Assurance

The organizer Jon D. Duke vouches that all listed participants have agreed to take part on the panel.

ClinicalTrials.gov: Adding Value through Informatics

Vojtech Huser, MD, PhD¹, Alexa T. McCray, PhD², Neil R. Smalheiser, MD, PhD³,
Asba Tasneem, PhD⁴, Chunhua Weng, PhD⁵

¹Clinical Center, National Institutes of Health, Bethesda, MD;
²Center for Biomedical Informatics, Harvard Medical School, Boston, MA;
³Department of Psychiatry, University of Illinois at Chicago College of Medicine, Chicago, IL;
⁴Duke Translational Medicine Institute, Duke University, Durham, NC;
⁵Department of Biomedical Informatics, Columbia University, New York, NY.

Abstract

ClinicalTrials.gov is a repository of registered clinical trials maintained by NLM containing detailed descriptions of trial sponsorship, design, and results (when available). ClinicalTrials.gov plays an increasingly important, pivotal role in evidence-based medicine, and serves a diverse audience ranging from clinical researchers, who are designing and conducting new trials and recruiting patients; systematic reviewers, who are summarizing the best available evidence regarding safety and efficacy; bio-entrepreneurs, who are looking for drug repurposing or new therapeutic opportunities; and patients, who may be looking for a suitable clinical trial that might accept them. This panel will present an overview of ClinicalTrials.gov and discuss several ongoing lines of informatics research that are adding value -- for example, using text mining to improve the computability of eligibility criteria, design attributes and outcome results and connect these with patient EHR data; linking a registered trial with the publications arising from that trial; and performing aggregate analyses across trials to extract reusable design knowledge, understand design patterns and trends, and uncover systematic biases. The panelists will also discuss challenges and opportunities for further evolution of ClinicalTrials.gov, particularly in light of emerging trends such as patient-centered clinical trials, or the use of unpublished trial data in meta-analyses.

General description of issues examined and brief description of each presentation

Alexa McCray will present an overview of ClinicalTrials.gov: its history, structure, policies, growth, evolution to include trial results, and current user populations¹,²,³.

Vojtech Huser will discuss studies on the completeness and accuracy of ClinicalTrials.gov data. He will review strategies for linking PubMed publications to the appropriate registered trial, as well as recent initiatives to make unpublished and raw trial data publicly available for analysis. He will also show examples how existing summary results data can be used in pharmacovigilance research⁴,⁵,⁶,⁷,⁸.

Asba Tasneem will describe the creation of an Analysis dataset: a database for Aggregate Analysis of ClinicalTrials.gov (AACT)⁹: its design, available database extract formats, utility for aggregate analysis from this dataset, and updating strategy. She will also present trends and outliers of aggregate analysis using ClinicalTrials.gov dataset¹⁰.

Chunhua Weng will describe a suite of text mining algorithms for ClinicalTrials.gov called EliXR. Then she will introduce COMPACT, a database of discrete clinical trial eligibility features, and VITTA, a scalable method for visual aggregate analysis of clinical trial eligibility features across multiple trials. Leveraging this analytical infrastructure, she will present novel findings about the patterns, trends, and biases of clinical trial designs and their implications for various clinical trial stakeholders¹¹,¹²,¹³,¹⁴.

Why is this topic timely? Who is the anticipated audience?

ClinicalTrials.gov is a major national resource that is rapidly growing both in size and scope. Recent changes in Federal policy have expanded the mandates for registering trials and reporting findings. The relatively recent establishment of the Clinical and Translational Science Awards (CTSA) Program and the National Center for Advancing Translational Sciences (NCATS) are two indicators of the fundamental importance of translational medicine to re-engineering the US health care enterprise, and management of clinical trial information lies at the heart of this effort. Many leading
informatics research groups have been using ClinicalTrials.gov as a test bed for advancing the state of the art of information extraction, data mining and visualization to assist in decision making.

For all of these reasons, our panel topic is timely and should draw a wide cross-section of AMIA attendees, including both academic researchers and hospital-based practitioners involved in Clinical Research Informatics. As well, the audience should include researchers, practitioners, health policy makers, and patient advocates, who are not currently involved in handling clinical trial data, but who are looking for opportunities to apply informatics techniques (e.g. text mining, EHR design, and data warehouses) to improve the generalizability of clinical trial designs and the efficiency of clinical trial conduct, and to make the design rationale more transparent to the public.

**List of discussion questions to enhance audience participation**

An increasing importance of ClinicalTrials.gov for clinical research informatics researchers is evidenced by the recent NIH policy update in November 2014 that aims to promote transparency for all NIH-funded clinical trials, whether or not they are subject to mandatory registration or results reporting. What other new Federal policies and national initiatives are on the horizon, which are likely to impact on ClinicalTrials.gov?

What impact is the Notice of Proposed Rulemaking (NPRM) for Clinical Trials Registration and Results Submission likely to have on greater sharing of clinical trial information and how can the informatics community contribute to maximizing that impact?

Published papers arising from a clinical trial often report different outcome measures than what was specified in the original registered trial. Similarly, adverse effects are often under-reported in the published paper relative to the results available in ClinicalTrials.gov. How can ClinicalTrials.gov be mined so as to more readily compare the data associated with a registered trial with data that is eventually published?

How are patients utilizing ClinicalTrials.gov? Are there challenges or opportunities for informatics to improve their experience finding relevant trials? What roles can patients play to improve clinical trial designs and conduct?

How can we engage different stakeholders to improve clinical trial designs and conduct?

**Statement from the Panel Organizer**

I attest that all participants have agreed to take part on the panel, and have contributed to the writing of the proposal.

Clinical Decision Support: How to Apply Standards to Deliver Knowledge-Driven Interventions

Robert A. Jenders, MD, MS, FACP, FACMI1,2, Guilherme Del Fiol, MD, PhD3
Kensaku Kawamoto, MD, PhD, MHS3, Howard R. Strasberg, MD, MS, FACMI4

1Charles Drew University, Los Angeles, CA
2University of California, Los Angeles, CA
3University of Utah, Salt Lake City, UT
4Wolters Kluwer Health, Sunnyvale, CA

Abstract
Clinical decision support (CDS) is receiving increasing attention as a way to help improve clinical practice and health behaviors. The use of health information technology (HIT) standards for encoding data, representing knowledge and delivering knowledge-based interventions can help facilitate implementation of CDS. However, many standards from numerous standards development organizations (SDOs) exist that are variously incorporated into vendor software, and consensus on the use of these standards is lacking. Moreover, newly proposed standards elaborated in the past year in CDS and related areas such as clinical quality measurement have increased the complexity of this domain. The recent emergence of the Health Level Seven Fast Healthcare Interoperability Resources (FHIR) standard for patient data representation is particularly pertinent.

Accordingly, the panel members, who are clinicians and co-chairs of the Health Level Seven International (HL7) CDS Work Group, will address two learning objectives. First, attendees will learn key details of extant and proposed HIT standards that are applicable to CDS which they may need to use in their work. Second, the attendees will recognize how these standards have been applied in actual implementations that are used to provide CDS that can be used to improve the quality of clinical care and outcomes.

General Description
The presentation will consist of two themes that align with the learning objectives of the panel presentation. The first theme will address the development of standards for knowledge representation and for related areas such as patient data representation and ontologies. In light of increasing emphasis by regulators and payers on measurement and reporting of clinical quality, more recent activity has included work to consolidate standards for representing and implementing clinical quality measures with standards for CDS. Within the past year, this suite of options for implementing CDS has been expanding with proposed standards to improve representation of clinical quality measures, CDS knowledge and the data needed to drive their implementation.

These standards and proposed standards may be classified into three categories, and the presenters will discuss details of standards in each. Knowledge representation standards provide a way to represent clinical and scientific knowledge in a structured way that can be shared among CDS systems and applied to data to produce CDS. Pertinent standards include the Arden Syntax, the Healthcare Quality Measure Format (HQMF), the Clinical Quality Language (CQL) and the CDS Knowledge Artifact Specification. A second category of CDS standards involves providing access to knowledge without transferring it among implementation sites. Relevant standards in this category include the Decision Support Services (DSS) and Infobutton standards. Finally, a third category of CDS standards provides formalisms for structured representation of data against which knowledge will be applied in order to deliver CDS. This category includes the Fast Healthcare Interoperability Resources (FHIR) standard and its profiles relevant to CDS, the Virtual Medical Record (vMR), the Quality Improvement and Clinical Knowledge Data Model (QUICK) and the Quality Data Model (QDM). State-of-the-art updates on these standards and proposed standards will be provided during this session. The goal is for attendees to recognize how these standards address the key challenges of implementing CDS and how they fit together to facilitate comprehensive solutions for delivering knowledge-driven interventions, emphasizing late-breaking developments as we refine and improve the building blocks for implementing CDS and related quality measures.
The panelists also will describe related efforts in other standards development organizations (SDOs), including the Object Management Group (OMG) and ASTM International, as well as work being conducted via the Joint Initiative Council (JIC) for global health informatics standardization. The context for these efforts, including public policy and collaborative projects that promote CDS, will be described.

The second theme will elaborate how these standards are incorporated in implemented health information systems to facilitate the delivery of CDS and how barriers to the implementation and use of CDS can be overcome. This will provide practical illustrations of how these standards can be used in health care delivery as well as identification of barriers to their use and ways to overcome these barriers. These illustrations will include descriptions of software and projects that leverage CDS standards to deliver knowledge-based interventions in a scalable manner, such as the OpenCDS initiative (www.opencds.org), the OpenInfobutton initiative (www.openinfobutton.org), and commercial implementations of the Infobutton standard. This second theme will be geared particularly toward the clinician who may be contributing expert knowledge to, supervising or using CDS systems in the context of EHRs.

The presenters are co-chairs of the HL7 CDS Work Group, the premier SDO for HIT. They also have experience as clinicians in deploying CDS solutions in a variety of settings. In addition, one of the presenters is the initiative co-coordinator for an effort sponsored by the US Office of the National Coordinator for Health Information Technology (ONC) and the Center for Medicare and Medicaid Services (CMS) to develop and validate a harmonized set of standards for CDS and electronic clinical quality measurement for potential use in US federal regulations. Together, they will present the details of the latest work in HL7 and other SDOs related to CDS, as well as solicit feedback that will help improve the formulation of these standards and their use in practice.

In particular, individual members of the panel will address key aspects of the overall themes:

- **Dr Jenders** will lay the foundation for the panel discussion by describing the overall context of the need for CDS standards. He also will describe the current status and future plans for the Arden Syntax and the Health Quality Artifact Reasoning and Expression Logic standards. He will further review related standards efforts in other SDOs besides HL7.
- **Dr Del Fiol** will describe the latest versions and deployment of the Infobutton standard.
- **Dr Kawamoto** will discuss efforts to harmonize standards for CDS with those standards for clinical quality measurement. He will also address CDS-related standards activity in the Object Management Group (OMG) SDO and deployments of the Decision Support Service standard through the OpenCDS and CDS Collaborative initiatives.
- **Dr Strasberg** will compare and contrast these various standards and review some important factors to consider when deciding which standards to use for different use cases.

**Explanation**

Emphasis on the use of CDS technology by regulators, payers and health systems coupled with new developments in standards in the past year that affect the implementation and use of this technology make the topic of CDS standards particularly timely. Increasingly, clinicians and health care organizations are being required to institute clinical quality improvement measures that leverage health information systems and to report their performance with regard to these measures. Clinicians, administrators and HIT workers are being called upon to implement, use and respond to this technology as part of efforts to measure and improve clinical quality and health outcomes. Standards for CDS facilitate these activities by supporting online access to knowledge and sharing of knowledge for interventions at the time of clinical decision-making. Key drivers of this activity include the regulatory requirement for meaningful use of electronic health record systems in the USA, as well as pressure to reduce the cost of care while improving the quality of care delivery. Indeed, in some cases (e.g., Infobutton for provider access to clinical evidence and individualized patient education), regulations require use of specific CDS standards.

Consequently, these standards are increasingly important. Knowledge about these standards is useful for clinicians and health care organizations that must make decisions regarding what software to buy and how to configure this software as part of their quality improvement activities. Such knowledge is useful for EHR system vendors, who must decide what standards to incorporate into their products. It is equally important for knowledge vendors and...
professional organizations that publish clinical guidelines and that consequently need to know how to represent the knowledge that they make available for use in information systems.

The expected audience for this didactic panel discussion includes
- Clinicians who will use or configure CDS technology;
- Clinical leaders and administrators who will purchase and deploy CDS technology;
- Health information technology workers who will implement and monitor this technology in the context of an overall electronic health record system; and
- Creators and maintainers of knowledge bases, clinical practice guidelines, clinical quality measures and the like.

The panel members lead efforts in the premier international standards development organization for health information technology to create and maintain these standards. They will provide insights into the development of the standards, how they can be used to achieve quality and other goals, and what the plans for additional development of CDS standards will be.

Discussion Questions

- Which standards do I use and how do I use them to improve the quality of clinical care and practice in my own health care organization?
- When shopping for clinical software, what standards should I insist be incorporated in order to comply with regulations and facilitate interoperability?
- Where can I obtain content for my decision support knowledge base?
- What standards and tools facilitate knowledge maintenance?
- What needs for CDS are unmet or not ideally supported by current standards, and how can this situation be improved?

Organizer Statement

All participants have agreed in writing to participate in the panel.

Acknowledgements

The panel organizer, Dr. Jenders, was supported in part by grants UL1TR000124 (NCATS) and 2U54MD007598 (NIMHD) from the US National Institutes of Health.
The Best of Imaging Informatics Research 2015

Panelists: Charles E. Kahn, Jr., MD, MS* and Bradley J. Erickson, MD, PhD*

*Professor and Vice Chairman, Department of Radiology, University of Pennsylvania
*Professor and Vice Chair for Research, Department of Radiology, Mayo Clinic

Abstract

Over the past decade, there have been rapid advances in imaging informatics research. As the storage and display of multidimensional image data has become commonplace and “off the shelf”, imaging informatics has focused increasingly on information not found in pixels and voxels. For example, new ontologies are now available to capture information in the imaging report. New structured data capture technologies and natural language processing capabilities provide discrete data that can be analyzed in concert with other data from the electronic medical record. Likewise, novel quantitative image analysis techniques give us new methods to diagnose clinical conditions and discern their time course. Machine learning methods applied both to images and imaging reports have accelerated our ability to extract meaningful clinical information from images. Several more practical advances, such as standardized workflow and analytic tools have modernized the practice of radiology and other clinical imaging specialties. Advances in imaging informatics research will be reviewed in this session.

Overview

Biomedical informatics spans a spectrum from basic to applied research, and from molecular to population scale. Imaging informatics concerns information at tissue and organ scales. In the past, imaging informatics at AMIA has focused primarily on image processing and analysis. As PACS have become commodities, and as radiologists have recognized the value of structured information for performance improvement and research, the discipline of imaging informatics and the interests of most AMIA attendees have converged. Yet many AMIA members are unable to stay current with the new developments in each sub-area of biomedical informatics. The data processing and visualization tools being developed by imaging informatics researchers will have broad appeal to the AMIA audience. Likewise, the extensive research to extract meaningful data from narrative radiology reports has wide applicability to other aspects of the electronic medical record that contain narrative elements. Thus, we expect this session to appeal to the typical AMIA attendee.

Methods

PubMed search terms for imaging informatics research have a low precision. However, we will perform a PubMed search using search terms “clinical AND imaging AND informatics”, filtered for the previous twelve months and for human research. In addition, we will review the table of contents for the past year of journals that are likely to contain imaging informatics articles, including the Journal of the American Medical Informatics Association (JAMIA), the Journal of Biomedical Informatics (JBI), the Journal of Digital Imaging (JDI), Radiology, and RadioGraphics. These searches will be supplemented by a call for nominations from luminary imaging informatics groups, including the Imaging Informatics Working Group of AMIA, the Radiology Informatics Committee (RIC) of the Radiological Society of North America (RSNA), the Informatics Commission of the American College of Radiology, and the Board of
Directors of the Society for Imaging Informatics in Medicine (SIIM). The bibliographies of the resulting publications also be searched using a “snowball” method.

The presentation will be divided into two sections. Dr. Kahn will present the best of research in ontologies, structured data capture, decision support, and other science focusing on data other than the images themselves. Dr. Erickson will present the best of research focused on imaging processing and image analysis.

**Panel Organizer Statement**

The panelists listed above have agreed to present the material and lead a discussion. A similar session will be presented at the annual meeting of the Radiological Society of North America (RSNA) annual meeting in December, 2015. This session is supported by the RSNA, the Society of Imaging Informatics in Medicine (SIIM), and the AMIA Imaging Informatics Working Group.
User-Centered Methods to Optimize Clinical Decision Support: Examples from Pediatrics with Applicability to All Care Settings

Dean J. Karavite, MSI\textsuperscript{1}, Eric D. Shelov, MD\textsuperscript{12}, Levon H. Utidjian, MD\textsuperscript{12}, Jeremy J. Michel, MD, MHS\textsuperscript{1}, Eli M. Lourie, MD, MBI\textsuperscript{1}
\textsuperscript{1}The Children’s Hospital of Philadelphia, Philadelphia, PA, USA
\textsuperscript{2}Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, USA

Abstract

Unintended consequences of health information technology (HIT) and clinical decision support (CDS) are frequently a result of poor design. Usability problems in electronic health records (EHR) have gained national attention. The need to increase effectiveness and reduce harm is vital and urgent. User-centered methodologies provide an array of methods to design systems around the requirements of the users and are critical to developing HIT that is safe and effective. In a series of vignettes, the panelists will describe applications of user-centered methods during the design of CDS projects in a multispecialty pediatric healthcare system. The panelists will review common user-centered design methods, suggest how to choose methodologies, and discuss both the benefits and challenges of following a user-centered approach in busy clinical settings. Panelists will describe examples of unintended consequences of CDS interventions and user-centered methods to prevent them. The panel moderator is formally-trained in user-centered methods and all panelists are pediatric informaticists with experience in the design and implementation of HIT/CDS interventions.

Learning objectives:

1. Describe system functionality and desired outcomes independent of implementation approach
2. Use low-fidelity mockups and heuristic review in the design of CDS systems
3. Select among potential user-centered methods to support project development

Relevance of User-Centered Methods

There is a prevailing belief that EHRs and CDS systems will improve patient health outcomes, yet there are increasing examples of unintended consequences, sometimes with disastrous results. Although EHR vendors may be able to apply some methods in user-centered design (e.g. cognitive walk through with simulated patients), other methods may be difficult to apply (e.g. directly observing clinical workflow). CDS implementation teams located in health systems are uniquely capable of applying user-centered methods in the design and evaluation of their projects. Individuals who attend this panel will be better equipped with a knowledge of user-centered methods to help increase the success of their projects and ultimately improve health outcomes.

Panel Description

The panelists will describe their experience applying user-centered methods in CDS projects using vignettes from a multi-specialty pediatric healthcare setting. The moderator—a usability expert—will facilitate discussion regarding practical issues that frequently arise in the selection and application user-centered methods in busy clinical settings.

Moderator: Welcome and session overview
Dean Karavite, MS (5 minutes)

Panelist #1: Decision support for neonatal fever
Eric Shelov, MD (10 minutes, followed by 5 minutes discussion)

Dr. Shelov advises on and builds CDS interventions with largely vendor-supplied tools for The Children's Hospital of Philadelphia’s Quality Improvement teams. Tool development can be challenging, with enthusiastic teams often proposing solutions and interventions before completing a proper workflow analysis. These initial ideas, while well-intended, can not only be suboptimal from the perspective of achieving outcomes, but may also introduce risk via unintended consequences. He will describe the five rights-based process he uses when partnering with project leaders to identify the right CDS approach for their improvement goal, minimize alert fatigue, and optimize
proactive decision support. He will review an example of an intervention developed with this approach to decrease length of stay for hospitalized febrile neonates.

Panelist #2: Asthma care plans across the continuum of care
Levon Utidjian, MD (10 minutes, followed by 5 minutes discussion)
Dr. Utidjian will discuss the implementation of a set of asthma management tools across the continuum of care including after hours telephone care, primary care, specialty care, emergency care and inpatient care. Motivated by patient safety concerns, he will describe how he developed use-cases based on clinician workflows and review of common data entry issues to guide implementation of a new set of asthma management tools. He will also discuss unintended consequence of how changing one workflow for data entry to improve one set of QI metrics inadvertently affected another set of performance measures.

Panelist #3: Delivering obesity management expertise in primary care
Jeremy Michel, MD, MHS (10 minutes, followed by 5 minutes discussion)
Dr. Michel will review how he gathered user requirements, used low-fidelity mock-ups and performed a limited usability test while simultaneously programming a functional decision support tool to implement obesity management best practices in busy primary care settings. He will describe unexpected consequences of his decision support intervention, how these issues were handled at the implementation sites, and plans for preemptively addressing these issues in the future. Examples of issues that will be discussed include (1) decreased system performance due to large patient data files, (2) adjustments necessary for site-specific workflows that were not in place at the initiation of the project, and (3) changes to laboratory tests that affected project functionality.

Panelist #4: Aches and pains of influenza immunization reminders in specialty care
Eli Lourie, MD, MS (10 minutes, followed by 5 minutes discussion)
Dr. Lourie will describe his experience designing decision support for antimicrobial stewardship in a pediatric primary care network. He will discuss the difficulties that arise when adding new processes to existing workflows, even when the clinical community is in agreement that the interventions are necessary. This lecture will explore barriers to the project's success, including static vs. interruptive alerts, provider performance feedback, and unintended consequences of the system.

Moderator: Facilitated discussion and closing
Dean Karavite, MS (25 minutes)
The facilitated discussion will explore strategies for selecting the most appropriate methods for typical projects. Obstacles that arise in the application of user-centered methods will be discussed along with recommendations for best practices to overcome these barriers.

Discussion Questions
The following guiding questions will be used to facilitate discussion:
1. Given what you learned from this project, what new innovations or changes do you envision for subsequent years so that project outcomes can approach their target threshold?
2. Which usability methods do you find most useful during the design phase?
3. When there are discrepancies between self-reported user behaviors with actual system usage (i.e. from audit trails), how do you bring that information back to the clinicians?
4. What challenges do you encounter when implementing CDS for Quality Improvement projects and how can you envision addressing them?

Moderator Attestation
The four panelists, Dr. Shelov, Dr. Utidjian, Dr. Michel and Dr. Lourie, have all agreed to participate in this didactic panel.
The Clinical Quality Framework Initiative to Harmonize Decision Support and Quality Measurement Standards: Defined Standards, Pilot Results, and Moving Beyond Quality Improvement

Organizer: Kensaku Kawamoto, MD, PhD, MHS

Panelists
Kensaku Kawamoto, MD, PhD, MHS
Marc J. Hadley, PhD
Tom Oniki, PhD
Julia Skapik, MD, MPH

Panelist Affiliations
a Department of Biomedical Informatics, University of Utah, Salt Lake City, UT
b MITRE Corporation, Bedford, MA
c Intermountain Healthcare, Murray, UT
d Office of the National Coordinator for Health IT, Washington, D.C.

Abstract
The Clinical Quality Framework (CQF) is a public-private partnership sponsored by the Office of the National Coordinator for Health IT (ONC) and the Centers for Medicare & Medicaid Services (CMS) to create a harmonized set of standards for clinical decision support (CDS) and electronic clinical quality measurement (eCQM). At AMIA 2014, experts presented preliminary results from the first year of this multi-year initiative. In this panel, CQF leaders will describe the standards developed, including the HL7 Clinical Quality Language standard for logical expression, the HL7 FHIR Quality Profiles for data exchange, the HL7 Quality Improvement and Clinical Knowledge model for logical inferencing, and several implementation guides leveraging these foundational standards. The panelists will then present findings from pilot deployments of the standards in various clinical domains ranging from cardiology to radiology, preventive care, infectious diseases, and oncology. The panelists will also describe partnerships with relevant initiatives beyond the quality domain, including the ONC Data Access Framework initiative, the Health Services Platform Consortium (HSPC), and the Clinical Information Modeling Initiative (CIMI).

Description
The panel will be organized as follows:

<table>
<thead>
<tr>

<td>30 min</td>
<td>Kawamoto</td>
<td>Panel discussion with audience</td>
</tr>
</tbody>
</table>

Dr. Kawamoto will serve as the moderator and introduce each of the panel members and their organizations. Dr. Skapik will describe the motivation and goals underlying the federal
government’s sponsorship of the CQF initiative. Dr. Hadley will summarize the standards developed by the CQF initiative. Dr. Kawamoto will describe pilot implementations of the standards, as well as partnerships with interoperability initiatives beyond the quality domain. Dr. Oniki will discuss the implications of the initiative beyond the quality domain. These presentations will be followed by a panel discussion with the audience moderated by Dr. Kawamoto.

**Skapik:** Dr. Skapik is the ONC lead of the CQF initiative. She completed her MD and MPH at the Johns Hopkins Schools of Medicine and Public Health, and her residency in Internal Medicine at the University of Pittsburgh Medical Center, joining the faculty in 2011. She is a former AAAS Science and Technology Policy fellow, working at the National Science Foundation in the Directorate for Computer & Information Science & Engineering working on their Smart Health and Wellbeing initiative. Dr. Skapik will discuss the motivation behind the federal government initiating and sponsoring the CQF initiative.

**Hadley:** Dr. Hadley is Senior Principal Software Systems Engineer at MITRE Corporation, an expert on eCQM, and Technical Lead for the CQF initiative. Dr. Hadley will describe the standards that have been developed through the CQF initiative, which include the HL7 Clinical Quality Language standard for logical expression, the HL7 FHIR Quality Profiles for data exchange, the HL7 Quality Improvement and Clinical Knowledge model for logical inferencing, and several implementation guides leveraging these foundational standards. The standards developed and validated through CQF will be available to policy makers for potential inclusion in future federal requirements relating to health information technology.

**Kawamoto:** Dr. Kawamoto is Associate Chief Medical Information Officer, Assistant Professor of Biomedical Informatics, and Director of Knowledge Management and Mobilization at the University of Utah. Dr. Kawamoto is co-Initiative Coordinator of the CQF initiative. Previously, he served as the Initiative Coordinator of the ONC Health eDecisions initiative, which developed the CDS standards being harmonized with eCQM standards in the CQF initiative. Dr. Kawamoto will present findings from pilot deployments of the standards in various clinical domains including cardiology, radiology, preventive care, infectious diseases, and oncology. Dr. Kawamoto will also describe partnerships with relevant initiatives beyond the quality domain to broaden the stakeholder community and reduce implementer burden. In particular, Dr. Kawamoto will describe a partnership with the ONC Data Access Framework (DAF) initiative, which is developing HL7 data interchange standards for Meaningful Use. He will also provide an overview of partnerships with the Health Services Platform Consortium (HSPC) and the Clinical Information Modeling Initiative (CIMI), which are ongoing semantic interoperability collaboratives with a scope beyond quality improvement.

**Oniki:** Dr. Oniki is Senior Medical Informaticist at Intermountain Healthcare and is the coordinator of HSPC and CIMI’s collaborations with the CQF initiative. Dr. Oniki will provide an overview of HSPC and CIMI and its goal to achieve more efficient and effective health care enabled by true semantic interoperability. Dr. Oniki will discuss the need for coordinated, isosemantic data models across interoperability initiatives, so as to avoid the proliferation of incompatible standards, reduce implementer burden, and maximize the adoption of a common set
of standards. He will then provide details on how HSPC and CIMI are collaborating with the CQF initiative.

Kawamoto: Dr. Kawamoto will lead a moderated discussion with the audience. The objectives of this discussion will be to answer questions from the audience and to obtain feedback from the audience to guide the future direction of standards development and implementation in the quality domain. The discussions questions listed below will be used to stimulate this discussion.

**Significance of panel topic and anticipated audience**

Current and proposed federal regulations include requirements for divergent CDS and eCQM standards. The CQF initiative has addressed this important challenge by developing and validating a unified set of standards for CDS and eCQM. Of note, the results of the CQF initiative will be available to federal policy makers for potential inclusion in future federal regulations. Therefore, the panel topic is timely, urgent, needed, and of great significance to the clinical informatics community. The anticipated audience is AMIA attendees interested in CDS, eCQM, data model standards, other interoperability standards, and/or federal regulations in this area, including members from academia, the public sector, and private industry.

**Discussion questions**

What do you think about the proliferation of standards and efforts to coordinate among standards development initiatives? Do you think the alignment efforts described are headed in the right direction?

What recommendations do you have for standards development and implementation in this area?

What gaps still exist in the available standards related to CDS and eCQM? How should we address those gaps?

What clinical domain areas can most benefit from standards-based, interoperable CDS and eCQM (e.g., immunizations, chronic disease management, chemotherapy)?

How should CDS and eCQM be leveraged in the short-term and long-term to improve clinical quality and health outcomes?

**Participation statement**

All proposed panelists have agreed to participate in the panel if the proposal is accepted.

**Acknowledgements**

The CQF initiative is supported by funding from the ONC and CMS, as well as by voluntary contributions of effort from various members of the CQF community.
Informatics Approaches to Supporting Emerging Accountable Health Care Delivery Models

Gilad J. Kuperman, MD, PhD (1), David W. Bates, MD, MSc (2), David C. Kaelber, MD, PhD, MPH (3), David A. Dorr, MD MS (4)
(1) NewYork-Presbyterian Hospital and Columbia University, New York, NY, (2) Brigham and Women’s Hospital, Partners HealthCare System, Harvard University, Boston, MA, (3) The MetroHealth System, Case Western Reserve University, Cleveland, OH, (4) Oregon Health and Science University, Portland, OR

Abstract

Medicare, Medicaid and commercial payers are creating incentives for efficient care delivery models and the health care market place is responding rapidly. The new incentives require health care delivery organizations – often for the first time – to include efficiency of care delivery as a key strategic goal. These dynamics are changing the way provider organizations are delivering care. New information infrastructures -- including analytics, work flow support for new care roles (e.g., care coordinators), information systems support for team-based work flows, information-enabled interactions with new business partners, and improved interactions directly with patients -- are emerging to manage patients in the new environment. The learning objective for this panel is for attendees to develop a better understanding of how leading organizations are addressing changes in health care payment models and the informatics-enabled approaches they are taking to support workflow changes, team-based care and the need for data-driven organizational and health care management.

General description.

The panelists are leaders at large organizations that are developing informatics-based approaches to the new health care environment. Each panelist will describe the following topics from the perspective of his organization: (i) the business drivers that are requiring health care organization to consider new, efficiency-based, approaches to care, (ii) the new models of care delivery that are being established, (iii) the information technology requirements emerging to support the new models of care, (iv) the current state of implementation, (v) challenges being faced and approaches to overcoming those challenges, and (vi) the role of informatics in the new environment. Dr. Kuperman will serve as the panel moderator and also as a panelist. This will be an “option 1 (didactic)” panel – each panelist will speak for 10’ with 5’ for questions and there will be 30’ at the end for audience-based discussion.

Description of each panelist’s presentation

Gilad Kuperman, MD, PhD, is Director for Interoperability Informatics at NY- Presbyterian Hospital (NYPH), a 2400-bed, $4 billion, organization in New York City. NYPH is participating in New York State’s $6 billion Delivery System Reform Incentive Program (DSRIP).

The goal of DSRIP is to reduce avoidable admissions and emergency department visits by 25% over a 5-year period. DSRIP is creating incentives for provider organizations to more effectively engage non-acute, social service and community-based organizations in the care of patients that consume large amounts of health care resources. The engagement of these organizations will allow the patient to remain in the community more effectively and avoid the use of costly emergency and inpatient-based services. Examples of such organizations include mental health, substance abuse, housing, nutritional, employment, home health, skilled nursing and other services. NYPH has engaged over 70 such organizations as part of its DSRIP project.

Care models have been designed that will rely on the ability to identify the relevant high risk patients, connect the patient with a care coordinator, and engage the relevant support service organization. The information systems requirements analysis has identified the need for (i) analytics support for cohort identification, management and quality reporting, and predictive modeling, (ii) workflow support for care managers, for example clinical documentation, tasking and roster management, (iii) health information exchange capabilities to support sharing of
clinical data among participants, (iv) enhancements to the electronic health record, such as alerts and worklists, (v) a patient portal that supports communication between patients and providers, and (vi) and application to support the work flow of community health workers. To support the program, NYPH will be leveraging and extending its existing enterprise analytics platform, its care coordination workflow application and its electronic health record. NYPH will be working with its regional health information organization (RHIO) to support health information exchange among the partners. The project has been in the planning stages since the Fall of 2014 and officially launches in April, 2015.

David Bates, MD, MSc, is the Chief Innovation Officer at Brigham and Women’s Hospital (BWH), which is a 700-bed, $1 billion/year organization which is part of the Partners Healthcare System, the largest integrated delivery system in New England. Currently, of patients at the BWH and in Partners, about 30% are in some type of ACO arrangement—nationally, about half the ACOs are in Massachusetts.

As a result, BWH and Partners are implementing an array of approaches to being to more effectively manage populations. For our current ACO populations, we risk stratify all of them, and have aggressively managed the highest-risk group, which has resulted in substantial decreases in the trend toward increasing total medical expenditures for this group. We are developing an Enterprise Data Warehouse (EDW), which will include data from both our Epic clinical systems, but also from a number of other sources, including an all-payer claims database. In addition, we are extending our analytics tools, attempting to develop our electronic tools around care coordination, developing our registry capabilities, and refining our ability to perform cost accounting. All of these areas will be discussed.

David Kaelber, MD, PhD, MPH is the Chief Medical Informatics Officer and Vice-President of Health Informatics at the MetroHealth System, a $1 billion/year integrated healthcare delivery network which includes a 500-bed hospital and over 20 outpatient clinics throughout northeast Ohio. The MetroHealth System is the public healthcare system for the greater Cleveland area and is a Medicare Shared Saving ACO. The MetroHealth System was also the first public healthcare system to begin to install Epic in 1999 in the outpatient setting and to achieve HIMSS Electronic Medical Record Adoption Model Stage 7 hospital and ambulatory recognition with the Epic electronic health record in 2014.

David Kaelber is responsible for all health informatics, patient engagement, and population health activities in the MetroHealth System. In support of the System's ACO efforts the MetroHealth System has developed a number of reporting registries, risk stratification tools, and interventions to improve our care and engage our patients more, especially outside of face-to-face visit. Specific informatics effort have included developing and implementing registries integrated into clinical work flows, deploying ACO metric dashboards, constructing risk stratification tools within our EHR, integrating payer data into our clinical data repository, maximizing use and functionality of our personal health record, and implementing technology to automatically call and text patients. All of these areas (and more) will be discussed.

Some specific examples to be discussed include:

1. ACO dashboards – how we have used “out of the box” vendor MSS ACO provider level and system level dashboards to track and improve ACO performance.
2. Informatics outreach interventions to improve ACO metrics - how we have used registries, bulk ordering, bulk messaging, and self-scheduling to double mammography screening rates in patients behind on mammograms.
3. Claims data – how we integrated claims influenza data to improve clinical ACO immunization metrics.

Dr. Kaelber is also on the Board of CareSource, the largest managed care Medicaid insurer in OH, and so will discuss informatics approaching to accountable care from the payer perspective as well.

David A. Dorr, MD MS is Associate Professor and Vice-Chair at Oregon Health and Science University. He studies how information systems, incentives, and practice facilitation can improve health care for our most complex patients while reducing costs.

In Oregon, the business drivers for efficient care models include an increasing prevalence of population-based payments, for example, from coordinated care organizations (CCOs) and through initiatives such as comprehensive
primary care from the Center for Medicare and Medicaid Services (CMS). To address the goals of these programs, the provider organization is giving increasing emphasis to care coordination, population management services, and risk stratified care management. The use of information technology has varied across initiatives; results from two trials that combined HIT with technical assistance will be described. Technology, while implemented, requires constant revision to meet program needs, and informatics is at the center of the difficult aspects.

**Why this topic is timely**

Accountable models of care that encourage efficiency of care are increasing in prevalence. In January, 2015, Secretary of HHS Silvia Burwell announced that HHS has a goal of tying 30% of HHS payments to alternative payment models “such as accountable care organizations” by the end of 2016 and 50% by the end of 2018. Medicaid and commercial payers similarly are changing their payment models. These changes require health care organizations to be more effective and efficient. These dynamics require health care providers to use their information systems in new ways that go far beyond the routine transactional capabilities of certified EHRs. Leading organizations are learning about the best way to support team-based care, new provider roles, risk-based approaches, patient engagement and health information exchange. The topics that will be covered in this panel will be very appealing to the AMIA Annual Symposium attendees that is interested in clinical informatics and the application of new and established technologies in the new environment.

**List of discussion questions to enhance audience participation**

1) What are the limitations of the current generation of EHRs in supporting the new emerging care delivery models and what additional, supportive or “wraparound” technologies are needed to meet the emerging requirements?
2) To what extent do the information technology requirements change over time as the organization matures in its experiences with accountable care models?
3) To what extent are patient facing technologies a critical part of the infrastructure to support accountable care?
4) Are mHealth or other innovative information technology approaches helping to support these new care delivery models?
5) What are the strengths and weaknesses of the current generation of readmission and resource utilization risk prediction models?
6) To what extent are the workflows for team-based care well-understood and easy to implement? How does integration among people, process and technology evolve over time?
7) How effective are current health information exchange strategies at supporting these new models of care and where is improvement needed?

**Statement from panel organizer that participants have agreed to take part.**

I, Gil Kuperman, attest that the other panel participants named here have agreed to participate.

Collaboration and Health Information Technologies: Towards Defining and Operationalizing the Collaboration Space

Craig Kuziemky, PhD 1, Madhu Reddy, PhD 2, Katie A. Siek, PhD 3, Sarah Collins, PhD, RN 4
1University of Ottawa, Ottawa, ON, Canada; 2 Northwestern University, Evanston, IL, USA; 3 Indiana University, Bloomington, IN, USA, 4 Partners Healthcare Systems, Boston, MA

Abstract

Despite calls for increased collaborative care delivery it is still a challenge to operationalize collaboration, and more specifically, to design and evaluate HIT to support collaboration. Reasons for that include a lack of integrated studies on different aspects of collaboration and a lack of research with an explicit focus on collaboration. However, studying collaboration can be challenging given the range of processes, providers and settings where collaboration takes place. To advance research on collaboration and HIT we need ways to bound studies of collaboration according to the different type of collaborations and the overall collaboration space where they exist. This panel will provide insight on how to define and operationalize the collaboration space. We will discuss the structure of the collaboration space and how it provides bounding for studies of collaboration as well as discuss clinical collaboration and patient centered participatory medicine as two specific contexts of collaboration spaces.

Introduction

Collaboration can be defined as ‘planned or spontaneous engagements that take place between individuals or teams of individuals, whether in-person or mediated by technology, where information is exchanged in some way (either explicitly, i.e. verbally or written, or implicitly, i.e. through shared understanding of gestures, emotions, etc.), and often occur across different roles (i.e. physician and nurse) to deliver patient care’ [1]. There have been recent calls for transforming the healthcare system to one that is collaborative across settings, diseases and governance structures [2]. While reports and commissions in many different countries have called for increased collaboration in the healthcare domain, operationalizing collaboration is a significant challenge because of the need to integrate various providers, processes, technologies and settings [3, 4]. We have seen a growing body of research on various aspects of collaboration including education [5], teamwork [6,7], patient-centeredness [8], technologies’ impact on collaboration [9], clinical content development [10], and designing and evaluating for collaboration [11]. However, a significant shortcoming is that these efforts have looked at isolated aspects of collaboration rather than the overall space where collaboration exists. Furthermore, collaboration is often only implicitly discussed in these studies rather than being the focal point of research.

Consequently, the lack of explicit focus on collaboration has led to challenges because of the lack of fit between HIT and the collaborative contexts where it is used [12]. Studies have shown that simply providing tools to support collaboration without facilitating the necessary behavioral support will result in less than ideal collaborative outcomes [13]. While there is a need to explicitly study collaboration, a challenge is that the collaboration space and the concepts associated with it are so varied that it is difficult to identify how to ‘bound’ studies of collaboration. The collaboration space refers to the technologies, contexts, processes and outcomes that are involved in collaboration [14]. To advance research on collaboration and HIT, we need to not only operationalize the concept of collaboration but also examine the different types of on-going collaborations that shape the collaboration space, and the role of HIT in supporting these various collaborations. We also need to look at how the structure of the collaboration space would be operationalized by different behavioral contexts of collaborative care delivery.

Given the calls for increased collaborative care delivery we believe it is important to engage in active dialogue about how collaboration currently occurs and how we can make it better. This panel will start to address that need identified needs by explicitly examining collaboration spaces, the role these spaces play in healthcare delivery, and how biomedical informatics and HIT can better support different collaboration spaces. This panel will bring together panelists with a wide variety of perspectives on collaboration and HIT from design, implementation, and use perspectives. Our goal for the panel is for each panelist to very briefly discuss their particular topic and then use the rest of the session to engage the audience in the issues of investigating and designing for collaboration.
Learning Objectives:
Attendees will be able to:
- Understand the current state of research on collaboration and the need to explicitly study collaboration
- Appreciate the challenges in operationalizing the collaboration space
- Identify ways of bounding the collaboration space to enable more focused studies of it
- Realize how different behavioral contexts influence the collaboration space

Discussion questions that will be posed to the audience include:
1. What are some components of collaboration that we need to focus on in research studies?
2. What are the most useful methods to capture collaboration?
3. How do different contexts of healthcare delivery impact collaboration?
4. To what extent does different HIT application support collaboration? How can HIT be better designed to support collaboration?

The target audience is HIT designers, clinicians and researchers with an interest in collaborative healthcare delivery.

Panelists and Their Insights on Operationalizing the Collaboration Space

The four panelists will each provide unique perspectives on how to operationalize collaboration.

Craig Kuziemsky, PhD – Dr. Kuziemsky has been studying the modeling, design and evaluation of HIT to support different collaborative contexts. His work has focused on the structural aspects of collaboration as well as behavioral aspects that shape the structure such as common ground. Dr. Kuziemsky is also interested in the different contexts in which collaboration occurs and how these contexts influence HIT design and evaluation. In his presentation Dr. Kuziemsky will focus on behavioral aspects of the collaboration space and the need to consider the relationship between structure and behavior in designing for collaboration. He will also discuss the need to consider trade-offs at the individual-collaborative interchange.

Madhu Reddy, PhD – Dr. Reddy has been studying collaboration and HIT from a sociotechnical perspective for the past fifteen years. He is particularly interested in the design, implementation, and adoption of healthcare technologies in highly collaborative and information-intensive clinical settings. In his presentation, Dr. Reddy will focus on ways on how we can “bound” collaboration so that researchers can focus on the actually collaborative aspects in a study. He will also discuss ways to operationalize the collaboration space.

Katie Siek, PhD – Dr. Siek has studied the interface between everyday people and clinicians through innovative wearable and mobile systems that connect with personal health record systems for over ten years. She is particularly interested in the validity of data transferred between groups and the implications of that data transfer on the overall patient-provider relationships. In her presentation, Dr. Siek will discuss some of the technical and social issues within the broader collaboration space. She will also highlight the implications of lay individuals sharing personal health management data with clinical collaborators.

Sarah Collins, RN PhD – Dr. Collins will focus on the collaboration spaces within inpatient clinical care units with a particular focus on tools to support interprofessional collaboration in critical care and patient safety. Critical care collaboration relies on a blend of formal and informal communication channels requiring reliable tools to exchange information (including safety concerns) and flexible tools to establish common ground for complex and patient-tailored or situation-specific clinical concepts. This presentation will describe the patient safety and patient-centered care planning dependencies woven through the interactive communication spaces of critical care interprofessional rounds [15], profession-specific handoff, profession-specific planning and decision making [16], and transitions of care. Specific tools that have been designed, developed, configured, integrated, and evaluated to support these dependencies at Brigham and Women’s hospital will be discussed, including challenges and remaining barriers. These tools include electronic plans of care [17], rounding tools, interprofessional safety checklists, communication microblog, patient facing safety reporting, and clinical dashboards.

Dr. Kuziemsky will also serve as moderator for the panel. All participants have agreed to take part on the panel.

References
The Implementation of Online Patient Portals in Safety Net Settings: The Realities of Meaningful Use Certification with Vulnerable Patient Populations

ABSTRACT
This panel will provide insights and early data about the experiences of safety net healthcare settings implementing online patient portals in order to meet Meaningful Use Stage 2 certification deadline during 2015. While the vast majority of US healthcare systems are in the midst of implementing patient access to online patient portal websites to allow patients to view their medical information online and communicate electronically with providers in between office visits, healthcare systems serving predominantly low-income and uninsured/publicly insured face unique challenges with patient as well as provider/staff engagement. In particular, these systems have developed strategies for engaging patients with limited health literacy and/or basic computer/Internet skills, such as dedicated portal training programs. They also have recognized the need for parallel processes for provider/staff engagement.

Learning objectives:
- Determine key lessons learned for developing support services/programs to support vulnerable patients in portal use, and present real-world Stage 2 Meaningful Use metric data from several safety net systems
- Identify policy and practice changes (specifically for Meaningful Use criteria) that might alleviate provider resistance to adopting secure messaging, especially in resource-constrained healthcare settings
- Formulate an approach to communicating with EHR/portal vendors when implementing a product that must meet the needs of safety net patients and providers (e.g., literacy, language standards)

PANEL
This panel will include leaders from both an urban, academic-affiliated safety net healthcare system as well as a community health center serving a rural population in California – with perspectives from research, practice, and leadership roles. The panel organizer (Dr. Lyles) is a health services researcher based at UCSF in the Center for Vulnerable Populations, who has been studying portal uptake across several healthcare systems in the past 5 years. Dr. Sarkar is practices internal medicine at General Medicine Clinic at San Francisco General Hospital, an urban public hospital and academic medical center. Dr. Ratanawongsa is the Chief Medical Informatics Officer for the San Francisco Health Network, which is a consortium of San Francisco Department of Public Health hospital- and community-based primary care clinics located across the city. Finally, Dr. Oryn is the Chief Medical Informatics Officer of an independent health center in Petaluma, California serving approximately 20,000 low-income and predominantly uninsured patients.

In 2015, we in the medical informatics community will continue to spend a significant amount of time discussing electronic health record (EHR) and portal implementation. This is particularly true as a large proportion of healthcare systems will moving from basic EHR implementation to patient engagement with portals in order to meet Stage 2 of Meaningful Use criteria to receive federal incentive dollars. While this huge increase in patient engagement EHRs is likely to revolutionize care in many ways, it is unclear how it will influence existing healthcare disparities for more vulnerable patient populations. This panel will shed light on this less-discussed, but critical issue, including advocating for clear next steps for research, practice, and policy for portal uptake among diverse populations – particularly related to literacy and language standards.

1. PATIENT PERSPECTIVES
Courtney R. Lyles, PhD (panel organizer)
Assistant Professor
University of California, San Francisco
Center for Vulnerable Populations

Summary:
Over the past year, Dr. Lyles has conducted in-depth interviews with patients at San Francisco Health Network, including 1) open-ended discussions about technology use and their ability/interest in using a portal website for healthcare management, and 2) thinkaloud interviews to assess usability and accessibility of the existing portal. San Francisco Health Network includes 11 community-based primary care clinics as well as 4 hospital-based primary care clinics at San Francisco General Hospital.
**Specific Findings to Date:**

We have conducted 16 in-depth interviews with chronic disease patients or their caregivers to date (with thinkaloud/usability interviews ongoing). The patient sample included 11 patients and 5 caregivers who were existing computer users. The mean age was 55 years, 50% were African American, 63% were male, and 70% reported using the Internet daily – although the range of computer abilities/tasks was broad, with a third of participants not using email.

The in-depth patient interviews focused on experiences with the healthcare system, technology use in everyday life, and interest in using an online portal to manage healthcare tasks. The major barriers to portal use were: concerns about security of information online, lack of technical skills/interest, and preferences for in-person visits/communication. Several participants discussed fundamental barriers to using an online portal, including: challenges with reading, writing, and typing (“I think that’s the reason why I don’t really use the computer a lot because it’s a lot of reading. Like I said, I’m not really a heavily educated guy.”); personal experiences with online security breaches/viruses; and a distrust of potential portal security measures (“Regardless of what a person says that this site is secured and all that, I just don’t believe it.”). Overall, participants also saw the value of a patient portal to increase the convenience of care coordination (“Instead of bugging the front desk…and they have to look everywhere for you…it’s convenient I think just looking at the calendar yourself.”) and support patient-driven communication (“I just hope that it’s just useful when you’re not at the doctor and you just want to know different information or contact your doctor.”).

2. **PROVIDER PERSPECTIVES**

Urmimala Sarkar, MD, MPH
Division of General Internal Medicine at San Francisco General Hospital
San Francisco, CA

**Summary:**

Dr. Sarkar has been a primary care provider in the General Medicine Clinic at San Francisco General Hospital for the past 8 years. Her presentation will focus on the provider experience in implementing a patient portal. This will include: 1) results from provider and staff survey and focus groups in the San Francisco Health Network that identified the major barriers and facilitators to portal use as a part of standard care, and 2) a qualitative examination of the content of early provider adopters of secure messages in this setting. This presentation is specifically timely given the direct link between patient engagement and provider/staff engagement, as previous evidence has demonstrated that one of the key successes to portal uptake among patients is the expectation that these websites extend existing provider relationships.

**Specific Findings to Date:**

To date, we have completed a survey of 77 primary care providers and staff (January and February 2015), assessing interest in recommending portal use to patients and expected barriers in using the system, particularly in using secure messaging through the portal. The sample included 46 physicians, 18 other providers (nurse, medical assistant, etc.), and 11 staff members, and about half of whom (45%) were from community-based clinics. The mean age was 42 years, and 77% were female and 46% were white. Overall, 45% said they would recommend the portal to most of their patients, and 38% said they would recommend the portal to some of their patients. Viewing upcoming appointments and lab results were the features seen as being recommended the most often. In terms of challenges for their patients in using a portal, English proficiency (81%), literacy (75%), unreliable access to computers/Internet (71%), and unstable housing (61%) were the biggest reported perceived barriers for patients. When considering using secure messaging through the portal their own practice, lack of time (68%) was the biggest barrier, followed by worry about patient overusing or sending irrelevant emails (47%).

3. **LEADERSHIP PERSPECTIVES**

Neda Ratanawongsa, MD, MPH
Chief Medical Information Officer, San Francisco Health Network
San Francisco, CA

**Summary:**

Dr. Ratanawongsa serves as the Chief Medical Information Officer for the San Francisco Health Network, which includes the outpatient clinics based at San Francisco General Hospital (such as General Medicine Clinic) as well as
the 11 community-based public clinics throughout the city and county of San Francisco. Her presentation will focus on the administrative and leadership experience in implementing an online portal across multiple clinic sites. Specifically, she will discuss the considerations for portal implementation given 1) the existing information technology infrastructure in safety net systems and 2) the realities of portal implementation given the linguistic and cultural diversity in an urban public healthcare setting.

Specific Findings to Date:
The San Francisco Health Network has developed several strategies for implementing a portal that will be most accessible to their population. This includes:

- A dedicated Patient Engagement Workgroup that includes membership from inpatient, outpatient, administration/leadership, quality improvement, and information technology teams/departments
- A partnership with the San Francisco General Hospital Library to be able to train patients how to 1) use computers for basic tasks, and 2) specifically enroll and access features of the MySFHealth portal website
- There have been multiple delays and challenges in working with the EHR vendor to make the portal website more accessible. The San Francisco Health Network is still waiting to be able to pilot a Spanish version of the product, as it is not currently available.
- The system has had to develop a robust plan for proxy access to ensure patients with limited English proficiency have the opportunity to dedicate a family member to access the portal website if appropriate

4. REFLECTIONS FROM A COMMUNITY-BASED CLINIC
Danielle Oryn, DO
Chief Medical Information Officer, Petaluma Health Center
Petaluma, CA

Summary:
Dr. Oryn is a practicing clinician and CMIO of the Petaluma Health Center in Northern California. This community-based clinic system includes 44 providers serving 32,000 patients in 3 clinics in Sonoma County, California. Her presentation will cover the range of patient, provider, and leadership experiences in implementation of the portal in this healthcare system serving primarily uninsured or publicly uninsured patients in a more rural area of the state.

Specific Findings to Date:
In this community setting, Petaluma has been an early leader in successfully registering their patient population for portal use, with 44% of active adult patients (seen in the last year) currently web-enabled. The key lessons learned to date include:

- Patients need help getting on to the system for the first time. Each clinic has had to create specific workflows to assist patients with registration.
- Language and literacy issues continue to be a struggle.
- Minors and proxy settings are not adequate with the EHR vendor – each clinic has also had to create policies and workarounds for this.

DISCUSSION QUESTIONS

- Do you think there should be specific Meaningful Use requirements for literacy and language access to portals?
- What are some steps that can be taken to alleviate provider resistance to adopting secure messaging, especially in resource-constrained healthcare settings?
- What are the differences in portal implementation challenges between urban and rural settings?
- How can vulnerable patient populations’ experiences of online portal use be improved?
- Please discuss your experiences delivering portal access (or other mHealth solutions) via mobile phones in your settings.

PARTICIPATION
All participants have agreed to take part on this panel during the AMIA conference in November 2015 in San Francisco, CA.
Health information technology and large-scale adverse events

Farah Magrabi PhD¹, Dean F. Sittig, PhD, FACMI², Jean M. Scott³, Peter M. Kilbridge, MD⁴.

¹Centre for Health Informatics, Australian Institute of Health Innovation, Macquarie University, Sydney, Australia; ²University of Texas – Memorial Hermann Center for Healthcare Quality & Safety, School of Biomedical Informatics, University of Texas Health Sciences Center, Houston, Texas; ³Informatics Patient Safety, Office of Informatics and Analytics, Veterans Health Administration, Albany, NY, USA; ⁴The Advisory Board Company, Washington, DC, USA.

There is an urgent need to address large-scale adverse events associated with health information technology (HIT) because the opportunity for harm to numerous patients is intensified with rapid implementation of systems worldwide. This panel will review current evidence about large-scale events including their impact on care delivery and consequences for patients. It will then use a case study of a high profile failure to discuss lessons for safe implementation and operation of present day HIT systems. The panel will then turn its attention to processes for detection and management of HIT events. And finally it will examine strategies for prevention and mitigation of large-scale events. The panel will aim to improve understanding about large-scale events and to transfer learnings about evidence-based best practice methods to improve preparedness, detection, response and recovery from HIT events, and to identify gaps and areas for further work.

Introduction

In February 2015, a Northern California hospital lost access to its electronic health records (EHR) for a week¹. At around the same time, hundreds of patients were exposed to the risk of harm for more than 14 hours when all the computer systems crashed at the Fiona Stanley Hospital, Australia’s most technologically advanced facility². A few months earlier, another health information technology (HIT) related event – this time in the state of Queensland – disrupted care delivery to thousands of patients when vital clinical systems were not available to doctors for several hours in every hospital across the state due to a data centre outage³. Another data centre outage affected 80 public sector organisations called trusts within England’s national health service (NHS)⁴. And in the US Veterans Health Administration, it took more than nine hours to restore services to the 17 sites in that were affected by an outage⁴.

There is now compelling evidence that such HIT events can introduce new, often unforseen, errors which can affect the safety and quality of clinical care and may lead to patient harm⁵. Like events associated with faulty equipment, HIT-related events because of their scale and scope can instantly mushroom into large-scale adverse events where individual events harm or increase the risk of harm to numerous patients⁶. There are few classes of intervention where risks to patients are rapidly increasing in scope. The opportunity for patient harm is intensified with growing numbers of large and complex HIT systems being deployed rapidly at organizational, regional and national levels to reform health systems worldwide⁷. For instance, 94% of US hospitals used EHRs in 2014, a five-fold increase since 2008⁸. Yet there is no active surveillance of the frequency and scope of adverse events involving HIT. A 2014 survey of US hospitals, found that large-scale events lasting 8 or more hours were a common phenomenon⁹.

This didactic panel will focus on large-scale adverse events associated with HIT. The types of technical problems and human factors issues contributing to large-scale events will be reviewed. The panel will then examine a case study of a high profile failure as well as processes at the Veterans Administration for detection and response to HIT events. The final presentation will examine strategies to proactively minimise the risks of large-scale events through processes for system design, implementation and use. The panel will be moderated by Farah Magrabi.

The problem: large-scale adverse events associated with HIT

Organiser and presenter: Farah Magrabi

This presentation will introduce the topic and review current evidence about HIT events as well as their propensity to lead to large-scale adverse events. In addition to the published literature it will draw upon a database of events...
including voluntary reports to the US Food and Drug Administration (FDA) and all the events over a 6-year period from England’s national program for IT to examine the nature and consequences of large-scale events\textsuperscript{16,13}. It will then give an overview of the types of technical problems and human factors issues as well socio-technical contextual variables contributing to events (e.g. training, cognitive load and clinical workflow). And finally, it will discuss the challenges in measuring the effects of large-scale events on care delivery and patient outcomes.

**Case study: Lessons from a large-scale failure**

*Presenter: Peter M. Kilbridge*

*This presentation will examine a large-scale failure* at the Beth Israel Deaconess Medical Center in Boston where it required four days to restore systems following a network disruption\textsuperscript{12}. It will specifically discuss the lessons that can be learnt from this event for safe implementation and operation of present day HIT.

**Detection and response to HIT events at the Veterans Health Administration**

*Presenter: Jeanie M. Scott*

*This presentation will provide an overview of the management of HIT events at the Veterans Health Administration.* Building upon standard processes for IT service management HIT events posing actual and potential risks to patients are explicitly managed by a dedicated patient safety team\textsuperscript{15}. The Informatics Patient Safety office is the focal point for the systematic and strategic evaluation of HIT safety risks through collaboration with the National Center for Patient Safety and IT organizations. This presentation will describe several examples including changes in HIT deployments\textsuperscript{16,17}. The main focus will be to identify practices during deployments to minimize risks.

**Improving HIT safety through design, implementation and safe use**

*Presenter: Dean F. Sittig*

In an attempt to create a set of proactive, self-administered EHR risk assessment tools, the US Office of the National Coordinator for Health Information Technology sponsored development of the Safety Assurance Factors for EHR Resilience (SAFER) guides\textsuperscript{9}. The SAFER guides are based on an extensive, human factors-type informatics research project conducted over a 2-year period. This research project identified six key principles that guided development of the SAFER recommendations. Data and systems are:

1. Available when and where needed
2. Only viewed by authorized users
3. Only modified by authorized users
4. Used correctly and completely throughout the organization
5. Designed and implemented to promote safe, effective, and efficient use
6. Used to monitor, detect, and report on the safety of the system

*This presentation will describe how the SAFER guides can be used to help healthcare organizations assess the safety and effectiveness of the EHRs as they are used in the clinical setting.* The main focus will be on best practices for preventing and mitigating large-scale events involving EHR downtime.

**Conclusion**

The presentations will show that events involving large and complex HIT systems are routinely posing risks to increasing numbers of patients. Participants will gain an insight into the types of technical and human factors issues that give rise to large-scale adverse events and their impact on patient safety. The panel will showcase practical strategies for improving the detection and management of HIT events and for addressing these issues throughout the HIT lifecycle. Participants will see that most safety problems with HIT are amenable to mitigation and amelioration with careful system design, implementation and use.

**Strategy to engage the audience**

At the conclusion of the presentations the moderator will invite the audience to participate by asking questions to various panel members or by voicing their views and opinions. If required the audience will be presented the following list of questions to stimulate discussion:

1. What do you think is the biggest safety risk for EHRs?
2. What is the most important thing an organization could do to reduce their safety risks?
3. What are the main challenges for researchers and practitioners to improve the safety of HIT?
4. How can we improve monitoring of the frequency and scope of large-scale adverse events?
5. What strategies can be put in place to improve the surveillance and response to HIT-related adverse events at organizational, regional, national and the international levels?

The goal of this discussion will be to transfer learnings and to identify gaps and areas for further work. The audience will also be given an opportunity to consult and seek advice from panelists about practical issues in preventing and managing large-scale events.

**Statement of the Panel Organizer**

All panelists have agreed to participate. The panel is supported by the International Medical Informatics Association (IMIA) Working Group on Technology Assessment and Quality Development.

Data Quality in Clinical Data Research Networks (CDRNs)

Panelists
Allison B. McCoy, PhD\(^1\), Michael G. Kahn, MD, PhD\(^2\),
Lemuel R. Waitman, PhD\(^3\), Jason N. Doctor, PhD\(^4\)

Moderator
Rahul Jain, MPH, CPHIMS\(^5\)

\(^1\)Tulane University, New Orleans, LA; \(^2\)University of Colorado, Denver, CO;
\(^3\)Kansas University Medical Center, Kansas City, KS; \(^4\)University of Southern California,
Los Angeles, CA; \(^5\)Louisiana Public Health Institute, New Orleans, LA

Abstract
National initiatives are increasingly leveraging the vast amounts of data availed by health information technology. PCORnet, the National Patient-Centered Clinical Research Network is one such example, and it aims to improve the ability to perform comparative effectiveness research by integrating data from clinical data research networks (CDRNs) and patient-powered research networks (PPRNs). One key component to the success of these networks will be ensuring the quality of the electronic health record and patient reported outcome data over time and across organizations. Clinical research informaticians have indicated challenges to data quality stemming from data integration, data capture, data exchange, and data standardization. Discussion items include the importance of data quality, a framework and plan for assessing data quality, the effects of health information system infrastructure on data quality, and data quality considerations for patient reported outcomes. Shared learnings from PCORnet stakeholders committed to the network’s excellence should help inform the national dialogue.

General Description
In the current healthcare environment, patients, healthcare providers, academics, insurers, and healthcare organizations are actively seeking the best clinical evidence to foster informed medical decision-making. To date, our capacity to provide real world evidence that can be broadly applied has been limited, in part, by relatively small and restricted datasets. PCORnet, the National Patient-Centered Clinical Research Network, has the potential to transform clinical research by providing the research infrastructure to allow investigators to conduct large comparative effectiveness studies using data from clinical practice in a large defined population. With a focus on patient-centered outcomes and research engagement, the results of these studies will provide important information to support evidence-based clinical care recommendations and to better explain multi-factorial contributors to health and illness, such as genetic, behavioral, social, and environmental factors across a spectrum of patients. PCORnet will integrate data from 11 Clinical Data Research Networks (CDRN) and 18 Patient-Powered Research Networks (PPRN). The CDRNs will each function as integrated research networks, including clinical data from multiple healthcare systems. Central to success of the CDRNs and PCORnet will be ensuring access, security, and quality of the data and appropriate linkage of data over time and across organizations. The need to ensure data quality is of particular importance given the tremendous amounts and the multiple sources of data to be included in the CDRNs; consideration must be given to the governance, evaluation, infrastructure, integration, and interoperability of data entered into the network to support data quality.

Anticipated Audience and Topic Importance
The efforts of PCORnet stakeholders committed to the development of a highly usable and effective infrastructure have the potential to affect patients, researchers, care providers, payers, employers and health systems. PCORnet’s large, national scale and recent timeline of funding make it especially important to all engaged in clinical research, in particular to clinical research informaticians with an interest or need in managing or utilizing vast amounts of clinical and patient reported data to derive new insight. The capacity to compare agreed upon indicators of data quality requires a coordination of approaches to evaluation among different organizations. The topic may also be of
interest to health systems administration and IT stakeholders as they consider the resources required to manage the embedding of best practices into operations activity and decision making. The topic provides an opportunity for other PCORnet and distributed research network or clinical research stakeholders within the audience to share in their learnings to ultimately validate or inform the practices for assuring the data quality practices and processes required to ensure confidence in new insight.

Discussion Questions

1. Why is it important to assess data quality in CDRNs?
2. How can my site assess the quality of data in a CDRN?
3. How can infrastructure choices affect data quality?
4. What special considerations are there in assessing the quality of patient reported outcomes?

Brief Description of Panelists and Presentations

Allison B. McCoy, PhD is an Assistant Professor in the Department of Biostatistics and Bioinformatics at Tulane University School of Public Health and Tropical Medicine and a research investigator at the Ochsner Health System Center for Applied Health Services Research. She is also a co-investigator for the Louisiana Clinical Data Research Network.

Dr. McCoy will present an introduction to data quality in CDRNs and provide justification for data quality assessment. She will also discuss approaches to governance to ensure data quality in CDRNs, including environmental scans and data characterization reports.

Michael Kahn, MD, PhD is the Director of Research Informatics at Children’s Hospital Colorado and the Biomedical Informatics Core Director for the Colorado Clinical and Translational Sciences Institute (CTSA). He serves as the informatics co-lead in PEDSnet CDRN, an informatics core member in the PORTAL network, and the site informatics lead for the NCATS-funded ACT network.

Dr. Kahn will present the value of developing a comprehensive data quality assessment framework and plan for evaluating data quality across multi-institutional CDRNs, including work that has established a broad-based collaborative network of individuals interested in establishing common approaches, models, and methods that can be shared across data networks that would support comparative and comprehensive data quality metrics, and work that evaluates existing, well-established data quality tools against this evolving harmonized model for data quality assessment and data quality reporting.

Lemuel R. Waitman, PhD is the Assistance Vice Chancellor for Enterprise Analytics, Director of Medical Informatics, and Associate Professor in the Departments of Biostatistics and Internal Medicine at the University of Kansas Medical Center. He serves as principal investigator for the Greater Plains Collaborative CDRN.

Dr. Waitman will present an overview of the infrastructure for CDRNs with respect to data quality, including the informatics interdependencies between electronic health record systems and enterprise data warehouses, and the challenges associated with integrating multiple sources of data (e.g., claims information, REDCap) into a single data mart.

Jason N. Doctor, PhD is an Associate Professor in the School of Pharmacy and the Director of Health Informatics at the Leonard D. Schaeffer Center for Health Policy and Economics at the University of Southern California. He is a co-investigator for pSCANNER CDRN.

Dr. Doctor will present the unique considerations and opportunities for evaluating the quality of patient reported outcomes, including those associated with measures, standardization and interoperability. Dr. Doctor will also report on the unique needs for further investments in characterization, and the potentials for examining relationships between clinical data and patient reported outcomes.

Rahul Jain, MPH, CPHIMS is the Digital Health Analytics Manager at the Louisiana Public Health Institute and the Digital Health Director for the Louisiana Clinical Data Research Network, responsible for quantified-self device data, data quality, data characterization and data standardization. Mr. Jain also manages the Analytics team for the
Greater New Orleans Health Information Exchange and is leading the building of a transitions of care infrastructure with Orleans Parish Prison.

Mr. Jain will serve as moderator for the panelist presentations and discussion.

All panelists named above have agreed to take part on the panel.
Panel: Public Implementation Resources for Genomic Medicine

Josh F Peterson, MD, MPH1; Marc S. Williams, MD2; Casey Overby, PhD2,3; Robert R. Freimuth, PhD4; Iftikhar Kullo, MD, PhD1

1Vanderbilt University School of Medicine, Nashville, TN; 2Geisinger Health System, Danville, PA; 3University of Maryland School of Medicine, Baltimore, MD; 4Mayo Clinic, Rochester, MN

Abstract

Genomic Medicine programs have proliferated as the evidence for implementing compelling pharmacogenomics use cases or targeted therapy accumulates. However, current electronic health records (EHRs) are under-developed for manipulating genomic data or communicating results to patients and providers. Three NIH-funded networks – Electronic Medical Records and Genomics (eMERGE), Pharmacogenomics Research Network (PGRN), and Implementing GeNomics In PracTicE (IGNITE) -- are creating health information technology (HIT) resources to help fill these gaps. Members of these consortia, which span academic medical centers and integrated health systems, are working to create educational tools, patient engagement technologies, clinical decision support resources, and common data models to exchange structured genomic results and guidelines. During this panel, speakers will review 1-2 resources that are available publically, and discuss how to leverage these resources to implement a new precision medicine or translational program. A panelist will describe methods and resources to encode genomic data and knowledge so that is can be shared between EHR environments. Secondly, a repository for storing and indexing genomic clinical decision support artifacts will be presented as well as efforts to use Infobuttons to provide just-in-time genomic medicine education. Finally, a panelist will present engagement technologies which can assist with communicating genomic results directly to patients.

Panel Overview

The recent growth of precision medicine has been fueled by striking variability in drug response and therapeutic outcomes, explained, in part, by genomic variation. Yet translating compelling use cases of Genomic Medicine to clinical care has been slow despite ongoing efforts to share implementation methods and develop best practice guidelines. EHRs have been identified as a key component of large-scale discovery and implementation; this is related in part to the complexity and scale of genomic data and in part to the need to integrate genomic risks with other clinical factors. However, the ability of EHRs to manipulate, transmit and communicate genomic data is surprisingly immature -- inhibiting both discovery and implementation. Known barriers include genomic results that are recorded as images or in other computationally inaccessible formats, the lack of an accepted standard for the interoperable exchange of data, and insufficient conventions for clearly communicating and displaying genomic data electronically.

Members of the panel have extensive experience with the implementation of genomic medicine at their respective institutions, and each belongs to one or more of the national consortia working to develop methods and best practices: the Pharmacogenomics Research Network (PGRN), Electronic Medical records and Genomics (eMERGE) Network and Implementing GeNomics in PracTicE (IGNITE).
The objectives of this panel will be to:
- Describe public resources related to implementation of genomic medicine
- Illustrate how these resources can be leveraged for implementation
- Identify the primary lessons learned when using the resources to inform implementations
- Discuss national resources that will help establish best practices for implementation of genomic medicine

This panel will follow the recommended format of 4 brief presentations with time for questions and discussion with the audience. Dr. Kullo will serve as a moderator and will ensure the presentations are well coordinated and contribute to the overall theme.

Presentation 1 (Dr. Freimuth): Standards to Support Genomic Medicine: Enabling the Exchange of Data and Knowledge

A significant investment of resources is required to implement genomic medicine within existing clinical electronic infrastructure. Standards that enable the exchange of genomic data and knowledge can reduce barriers to implementation. In this presentation, Dr. Freimuth will discuss efforts by HL7, ClinGen, and the Institute of Medicine Action Collaborative to develop robust methods for exchanging clinical genomic data. He will also describe projects by the PGRN Translational Pharmacogenomics Program (TPP), Clinical Pharmacogenomics Implementation Consortium (CPIC), and ONC Standards and Interoperability Framework (Health eDecisions) designed to facilitate the sharing of knowledge, including that expressed in clinical genomic guidelines and decision support rules, through structured knowledge representation schemes.

Presentation 2 (Dr. Peterson): Development and Initial Applications of a Repository for Genomic Clinical Decision Support Artifacts

Dr. Peterson will present the development and initial rollout of a repository for clinical decision support artifacts produced by institutions with genomic medicine programs. The repository reflects the myriad ways that institutions have developed clinical decision support and other customizations of their electronic health records (EHRs). He will discuss the functionality of the repository including capacity to store, index, and disseminate artifacts, and demonstrate their ability to act as a design model for new implementations. Policies for artifact submission, access, and site control over submitted content will also be discussed, as well as ways the artifacts are contributing to new translational programs. In addition to presenting the CDS Knowledgebase, Dr. Peterson will outline the process of transferring trusted guidelines into CDS interventions which are well integrated in clinical workflow.

Presentation 3 (Dr. Williams): Patient Powered Precision Medicine: Leveraging HIT to facilitate engagement

Patients are increasingly engaged in their health care through a variety of health information technologies. The role of the patient in genomic medicine remains uncertain given the volume, complexity and uncertainty of the information. However there are strong arguments supporting partnering with patients to manage genomic information. In this session, Dr. Williams will present the results of research in three areas: 1) the use of informatics tools to report genomic test results to both
patients and providers, 2) the development of a dynamic standards based interactive application, Genome Compass, that has the potential to enhance communication between patients and providers and 3) a prospective clinical trial that will study the impact of these tools on patient understanding, satisfaction, engagement and adherence as well as patient-provider communication. Dr. Williams will also address the HIPAA and privacy related issues related to the use of pharmacogenomic data within the EMR and patient-facing genomic reports.

Presentation 4 (Dr. Overby): Infobuttons as a mechanism for just-in-time education and clinical decision support for genomic medicine.

Integrating genomic information into the EHR requires just-in-time education of clinicians who may not have a background in the significance of particular genetic variants relevant for their patients’ care. Infobuttons are being explored as a decision support tool to provide such just-in-time education via context-specific links within the EHR. Dr. Overby will provide an update on progress to date and future plans to use infobuttons to link with external and institution-developed genomic medicine content within the EHRs of institutions pursuing genomic medicine projects.

Discussion Questions:
1) How do the resources discussed by the speakers work within vendor products and environments?
2) What are the current implementation resource gaps and are how could these to be addressed by federally funded projects?
3) What is the model for growing and maintaining genomic medicine HIT resources?
4) How do we assess the impact of genomic HIT tools on engagement of providers and patients?

About the Speakers:
The panelists were selected with broad knowledge of both applied informatics in the area of genomic medicine and direct involvement in the creation of many of the discussed resources. Robert R. Freimuth, Ph.D., is an Assistant Professor of Biomedical Informatics in the Department of Health Sciences Research, Mayo Clinic, and among many positions within the genomic medicine community, leads the PGRN Pharmacogenomics Ontology network resource and is past Chair of the AMIA Genomics and Translational Bioinformatics working group. Josh F Peterson, MD, MPH is an Assistant Professor of Biomedical Informatics and Medicine at Vanderbilt University Medical Center working with the IGNITE, eMERGE, and TPP consortia on implementation projects. Marc S. Williams, MD, FAAP, FACMG is a clinical geneticist, board-certified in clinical informatics and directs the Genomic Medicine Institute of the Geisenger Health System. Casey L. Overby, Ph.D. is a faculty member in the Program for Personalized and Genomic Medicine within the University of Maryland School of Medicine and Adjunct Investigator at Geisenger Health System involved in ClinGen, eMERGE, and IGNITE. The moderator, Iftikhar Kullo, MD is a Professor of Medicine at the Mayo Clinic with a focus on electronic health record-based genomic discovery and implementation of genomic medicine.

Affirmation
All proposed panel members have been personally contacted by Josh Peterson and have agreed to participate in this panel. The speakers report no conflicts of interest.
Title: Perioperative Clinical Decision Support: Improving Care of the Surgical Patient through Informatics

Moderator: Karl A. Poterack, MD
Assistant Professor of Anesthesiology
Diplomate in Clinical Informatics, American Board of Preventative Medicine
Medical Director, Applied Clinical Informatics,
Office of Information and Knowledge Management
Mayo Clinic
Phoenix, AZ

Panelist 1: Patrick Guffey, MD
Assistant Professor, Anesthesiology
Children’s Hospital Colorado
Aurora, CO

Panelist 2: Brian W. Pickering, MB, BCh
Assistant Professor, Anesthesiology
Mayo Clinic
Rochester, MN

Panelist 3: Bala Nair, PhD
Associate Professor, Anesthesiology & Pain Medicine
University of Washington
Seattle, WA

Panelist 4: Richard H. Epstein, MD
Professor of Anesthesiology
Diplomate in Clinical Informatics, American Board of Preventative Medicine
Certified Professional in Healthcare Information Management Systems, HIMSS
Vice Chair, Anesthesia Information Systems
Sidney Kimmel Medical College at Thomas Jefferson University
Philadelphia, PA

Abstract
The perioperative period is a complex environment that can benefit significantly from the implementation of clinical decision support (CDS), given the large volume and velocity of data, the presence of many distractions, and increasing documentation requirements. Panel participants will describe projects they have successfully implemented that relate to four separate domains of perioperative CDS. Implementation of post hoc provider-specific feedback through the use of dashboards will be discussed in the context of improving the quality of patient care. Guidance of provider activities at the point of patient care in the operating room through integration of data from physiologic monitors, anesthesia machines, and the electronic health record and delivery of timely advice will be presented. A CDS system to facilitate compliance with the new SCIP 4 protocol related to control of blood glucose following cardiac surgery will be described. Translation of published research regarding Bayesian statistical predictions for time remaining during surgical cases to a real-time whiteboard to facilitate operating room management CDS will be shown. Panelists will discuss issues related to implementing CDS in the context of modern electronic health systems in which access to necessary data in near real-time has proven to be challenging.
**General Description of the Panel**

The panel comprises 4 individuals and a moderator, all of whom are directly involved in the development and implementation of perioperative Clinical Decision Support (CDS) systems, and several who have published extensively in the area. Following Greenes’ characterization of CDS as “the use of information and communication technologies to bring relevant knowledge to bear on the health care and well-being of a patient,” the panel will discuss four different aspects of CDS as applied to the perioperative period. These include individualized post hoc reporting to improve performance, real-time recommendations based on application of artificial intelligence to physiologic and patient monitoring data to guide clinical care, alerts and reminders to facilitate compliance with clinical protocols, and statistical forecasting as an aide to operating room management. A brief description of each presentation follows:

**Moderator** Karl A. Poterack, MD

**Presentation:** Overview of Perioperative Clinical Data support

**Summary:** The scope of clinical decision support during the preoperative, intraoperative, and postoperative periods will be briefly summarized.

**Panelist 1:** Patrick Guffey, MD

**Presentation:** Driving Reporting and Quality Improvement

**Summary:** Healthcare providers seldom have access to self-serve analytics on their performance. I will highlight best practices in how to design, implement, and refine provider dashboards across multiple domains. In addition, change management strategies to support access to this information will be described. Brief case studies in performance improvement by using this methodology will also be presented.

**Panelist 2:** Brian W. Pickering, MB, BCh

**Presentation:** Reducing the Risk of Perioperative Harm: A Case Study in the Development, Implementation and Sustainability of an Informatics-Driven Approach

**Summary:** Preventable harm has become an important quality improvement target. As patients travel through their perioperative journey they encounter multiple healthcare providers and handoffs from one care location to the next. There is a risk of information being lost during transitions with resultant delayed or omitted care plan elements. In this presentation, a case history of the development, deployment, impact and sustainability of informatics tools developed to support compliance with SCIP 4 glucose control are discussed.

**Panelist 3:** Bala Nair, PhD

**Presentation:** Development and Use of the Smart Anesthesia Manager (SAM): An AIMS Based Real-Time Decision Support Module

**Summary:** Development and application of a decision support module that analyzes anesthesia information in near real-time to detect on-going clinical issues will be described. Detected clinical issues are brought to the attention of the anesthesia provider immediately so that remedial steps can be taken quickly. Factors to be considered when designing and implementing of a real-time decision support module will be discussed.
Panelist 4: Richard H. Epstein, MD

Presentation: Real time Decision-Support for Operating Room Management on the Day of Surgery

Summary: An important aspect of operating room (OR) management on the day of surgery is to understand when ongoing cases are likely to be completed, since actual durations differ the scheduled times. The duration that a case has been underway can be used to predict the median time when the case will exit the OR, based on Bayesian statistics. The translation of the theoretical framework of this approach to its application on the OR electronic whiteboard will be described.

Timeliness of panel and anticipated audience

There is an increasing need for clinical decision support to assist healthcare providers working in the perioperative area with escalating tasks related to complying with regulatory and compliance requirements, adhering to care protocols, following clinical pathways, managing workflow, and processing the voluminous data that is presented from physiologic monitors. However, lack of simple and efficient access to real-time patient care data within the major enterprise EHR systems is a major barrier to the application of real-time CDS. This panel will be of interest to those involved in the development, implementation, and use of perioperative CDS, including anesthesiologists and certified registered nurse anesthetists, nurses who work in preoperative and postoperative care units and intensive care units, surgeons, and administrators charged with oversight of billing, compliance, and regulatory issues.

Discussion questions to enhance audience participation

1. What issues have you encountered in accessing real time data from your electronic health systems?
2. What challenges have you experienced implementing CDS in the perioperative area?
3. What unintended consequences of CDS have you experienced in your organizations?
4. What governance processes do you have in place to approve implementation of CDS?
5. How do you monitor the effectiveness of CDS?
6. What successes have you experienced in the application of perioperative CDS?
7. What failures have you experienced in the application of perioperative CDS?
8. What regulatory requirements have your organization considered when developing and implementing CDS?

Panel organizer attestation that all participants have agreed to take part on the panel

All panelists have agreed to participate. Abbreviated, NIH-type Biosketch CV’s have been provided for each.

Panel Sponsorship

This panel was suggested by Vitaly Herasevich, Chair of the AMIA Intensive Care Informatics Working Group, who was involved in the preparation and submission of this proposal. The panel is sponsored by the Working Group.
Harmonization of ICD-11 and SNOMED CT – Not just mapping!
Practical and Theoretical Lessons & Benefits to Users and Implementers

Alan L Rector, MD PhD, James Campbell MD, Bedirhan Ustun MD PD, Christopher G Chute MD DPH, Harold Solbrig MSc

1University of Manchester, UK, 2University of Nebraska Medical Center, Omaha, Nebraska, USA, 3World Health Organization, Geneva, Switzerland, 4Johns Hopkins University, Baltimore, Maryland, USA, 5Mayo Foundation, Rochester, Minnesota, USA

Abstract

ICD and SNOMED CT were designed for different purposes – ICD for statistical reporting and epidemiological studies; SNOMED CT for documenting clinical care. They conform to different semantics – ICD is a closed monohierarchy in which sibling entities must be mutually exclusive and jointly exhaustive. SNOMED is an open polyhierarchy based on description logic. ICD has a strong requirement to focus on identifying diagnosis and underlying cause of death; SNOMED has an equally strong requirement to reflect the evolution of clinical understanding. ICD’s usage has clearly outgrown its historical structure. Updates occur at long intervals, and migration between versions is costly. To meet these problems and harmonize with SNOMED, ICD-11 uses a radically new three-component architecture: A “Common Ontology” that will correspond to an agreed subset of SNOMED, a “Foundation Component” structured around this ontology, and “Linearizations” that correspond to the existing classification, plus algorithms that link these component. The result is expected to simplify generating maps between SNOMED and ICD and to provide a stable platform for the evolution of ICD. The development has required clarifying the semantics of both ICD and SNOMED and has important implications for anyone working with either or attempting to harmonize other systems with them.

General Description

The panel will present and stimulate discussion on the underpinnings and practical outcomes of the architecture for ICD 11 and the harmonization of ICD-11 and SNOMED CT. Achieving the harmonization has required clarifying the semantics of both ICD and SNOMED and developing systematic means of using one to support the other. This is not a matter of “mapping”. The two systems and their requirements are too different. Rather it requires fundamental clarifications of their semantics, linkages between their conceptual models, and creation of a novel architecture for implementation. It has involved overcoming fundamental misconceptions and misunderstandings on each side: e.g. the distinctions between “ontological” definitions and “clinical descriptions”, between OWL/DL queries and concept expressions, and between “condition oriented” and “situation oriented” interpretations of the entities to be classified plus a clearer understanding of ICD’s “residual categories” – e.g. “not otherwise specified” and “not elsewhere classified”.

The panel will discuss these and other issues with respect to both in ICD-11 and SNOMED. More broadly, it will discuss the respective roles of logic based “ontologies” and the “classifications.”

It will also discuss the practical implications for users of both SNOMED and ICD-11, the further evolution of the ICD, and issues in migration from ICD-10. The architecture represents a means of reconciling the conflicting requirements for stability and support for change that bear particularly strongly on ICD. It is expected that in future ICD-11 will be more flexible and evolve more smoothly than previous versions. Using ICD and SNOMED together should become easier and more standardized, and the effort devoted to developing “mappings” should be reduced.

The issues raised are at the core of the Health Informatics agenda for achieving interoperability between clinical and epidemiological use cases. The existence of multiple conflicting terminologies continues to be a major challenge, often aggravated by advocates of one misunderstanding the purpose and requirements of another. The cost of migrating between versions or between terminologies has proved daunting. Although there have been many attempts at “mappings”, this is the first thoroughgoing attempt to harmonize two disparate systems that addresses the fundamental differences between them in both requirements and implementation and respects the semantics of each.
Presentations and Presenters

Goals and Constraints on the ICD: Bedirhan Ustun (WHO)

The ICD is an international standard that serves many purposes. It was developed originally for reporting mortality and morbidity. It has over a century of history behind it and a large body of expertise around the world in its use. However, many groups wish to use it far beyond the intent of original statistical categorization including for recording diagnoses in clinical and epidemiological studies, quality and safety reporting, and development of diagnostic groupings for outcomes and reimbursement. Variations in terminological, linguistic, and clinical practice across countries and over time add more complexity in comparing data. The comparability of various versions and meaningful exchange of data between different uses is a major challenge. It is therefore essential to move to an electronic infrastructure that will:

1. Enable users to ensure comparability of data captured in different settings by pointing to international reference standards for diagnostic categories (e.g. defining hypertension, anemia, depression etc.) independent of language artefacts.

2. Link the different diagnostic formulations used in different levels of health care in a consistent way so that primary care, secondary care and other health workers can exchange information reliably.

3. Link to standard terminologies (such as SNOMED-CT, LOINC, etc), Classifications (ICF, ICHI, ATC) and Ontologies (Gene Ontology etc) so that the electronic processing of data is performed in a standard way.

Overview and motivation: CG Chute (Chair: ICD Revision Steering Group)

ICD-11 aims to reconcile the conflicting requirements for greater flexibility and for continuing stability within ICD. At the same time it aims to achieve a harmonization with SNOMED CT. Since SNOMED CT is aimed at clinical practice and ICD primarily at statistical returns, many systems will need both. If the goal of collecting statistical data automatically from EHRs is to be achieved, then we need to be able transform SNOMED CT encoded data to ICD. Although maps exist for ICD-10, their production has been a long and expensive process fraught with problems and without any common principled foundation.

There are two fundamental ideas that underlie ICD-11 and its harmonization with SNOMED CT:

1. To separate the components that correspond to the existing and previous ICD-10 versions – the “Linearizations” – from a generic, polyhierarchical “Foundation Component.” The “Joint Mortality and Morbidity Linearization,” will be the direct successor to ICD-10, but alternative organizations are possible, e.g. for rare diseases, primary care, oncology, etc. It is hoped that this same mechanism will allow for representation of ICD 10 and existing clinical modifications, but this has yet to be demonstrated.

2. To use a “Common Ontology”, agreed jointly with SNOMED CT, and sharing its description logic based semantics, as the skeleton for the “Foundation Component”. The “Foundation Component” contains much more than the “Common Ontology”, but building it around the “Common Ontology” is expected allow largely algorithmic mapping between the SNOMED CT and ICD-11 and agreement on common text definitions.

Ontologies and Classifications, Definitions and Descriptions: The Role of a “Common Ontology”: Alan Rector (ICD revision steering group)

“Ontologies” and “Classifications” in the senses used by SNOMED CT and ICD, respectively, are fundamentally different. Ontologies are polyhierarchical; classifications are mono-hierarchical. Ontologies use logical semantics based on meaning; Classifications use pragmatic semantics based on use. Likewise “definitions” corresponding to the ontological meaning expressed in logic are fundamentally different from clinical descriptions. For example, ontologically, a “myocardial infarct” is (roughly) “death of some part of the myocardium due to ischemia”; clinically it can be described as “Manifesting variously as sudden death, acute crushing chest pain,…”. These two key distinctions and their effect on the ICD SNOMED CT harmonization process will be discussed as will the problem of choosing amongst the possible alternative semantic interpretations of SNOMED CT and ICD definitions’.

Implementation issues: Evaluating the Completeness and Correctness of the Classification/Ontology Linkage: Harold Solbrig (SNOMED CT/IHTSDO)

The foundation ICD-11 classification system is defined using a set equivalence expressions, either directly with existing SNOMED CT concepts or indirectly, using “post-coordinated” expressions to identify the intended meaning of the category. These equivalence expressions must determine the conditions that are both necessary and sufficient
for a given clinical event to be recorded as belonging to a particular category. This step, in turn, drives the linearity process, where the specific ICD-11 categories are combined using inclusion and exclusions that determine where a specific event should be categorized when more than one category is possible.

It is not possible to do this second step directly, because the requirement that the linearizations be single hierarchies means that, if a category is logically a subclass of more than one class, then one parent class must be chosen and the others excluded. This cannot be done within the Common Ontology itself because to do so would violate its logic-based semantics. Instead, it must be done by querying the resulting structure of the Common Ontology using a query language. These issues will be explained and the query language being developed within the IHTSDO presented briefly. Current practical efforts are being proven in the cardiovascular/circulatory sections.

**Practical experience from Mappings and semantic alignment: Jim Campbell (SNOMED CT/IHTSDO)**

Recent publication by the IHTSDO of rule-based mapping from SNOMED CT to ICD-10 has revisited and quantified differences in conceptual models employed by the two terminologies. Observations regarding semantic mismatch in ICD-10 maps are informing the alignment between SNOMED CT and ICD-11. Co-development requires that complete ontological definitions be developed for ICD-11 classes and that these be fully defined in expressions employing the common ontology subset of SNOMED CT. Exemplar cases of semantic misalignment from ICD maps will be presented, relating this to the semantic analysis and redefinition of ontologies that has developed from harmonization case studies. Preliminary results for the cardiovascular chapter indicate that this alignment is non-trivial. The issues raised by this experience will be discussed.

**The Future Directions and other Features of ICD-11: CG Chute (Chair: ICD revision steering group)**

The primary efforts of the present revision remains to deliver to the global community a disease and condition classification that is scientifically current, broadly useable, and addresses the needs of many stakeholders. The current architecture displays sufficient flexibility to accommodate a large spectrum of use cases through multiple linearizations, each anchored to the semantic core of the Foundation Component, and in turn to SNOMED CT.

Although not yet fully populated by the time of its initial release, ICD-11 will eventually include a rich and robust Content Model in the Foundation Component. The Content Model will incorporate structures for diagnostic criteria (to accommodate multiple paths and technology settings), more complete etiologic and genomic detail, a fully coded rendering of disease and condition characteristics such as anatomy, disease specific severity, impact on human functioning, and possibly additional resources. These will be refined after the official ICD-11 release, to contribute to the scientific completeness and usefulness of the ICD-11 information family into the future.

**Questions for Discussion**

- What might be the migration path to ICD-11, with or without SNOMED CT?
- Aren’t the Linearizations enough? Do implementers have to deal with anything else? Do clinicians?
- Why isn’t SNOMED CT enough? Why isn’t ICD enough? Why both? Does this mean we can just use ICD? Just use SNOMED CT?
- How will these developments affect coders? Clinicians? Implementers?
- Will you have to understand Description Logics to use ICD-11? What benefits if you do? Will you have to understand SNOMED CT to use ICD-11? ICD-11 to use SNOMED CT?
- What will be the best way to manage proprietary terminologies in conjunction with ICD-11?
- Will CM versions of ICD still be needed?

Developing Natural Language Processing Systems for Healthcare

Panelists
Ruth Reeves, PhD¹, Wendy W. Chapman, PhD², Dezon Finch, PhD³, and Jennifer H. Garvin, MBA, PhD⁴

Organizer & Moderator
Glenn T. Gobbel, DVM, PhD, MS¹,⁵

¹Tennessee Valley Health System VA, Nashville, TN; ²University of Utah, Salt Lake City, UT; ³Tampa VA, Tamp, FL; ⁴Salt Lake City VA Medical Center, Salt Lake City, UT; ⁵Vanderbilt University, Nashville, TN;

Abstract
Natural language processing (NLP) systems can help uncover medical knowledge buried within clinical free text. Despite multiple demonstrations of the clinical utility of NLP, its use for biomedical research and patient care remains limited. A detailed overview of the steps involved and potential challenges associated with creating an NLP system could help potential users of such systems; they could use this knowledge to assess feasibility and identify the types of expertise required for system development and implementation. This panel will delineate four key tasks commonly required when developing a clinical NLP system: 1) document selection; 2) annotation; 3) NLP software development; and 4) clinical implementation. Presenters will explain the role of each task in NLP system development, define the subtasks required, describe approaches for estimating the effort and time requirements, and delineate approaches and tools for assisting with task completion. Attendees will acquire an understanding of the common requirements for NLP system development, an appreciation of potential tools to help with the process, and be better able to assess whether and how to approach using NLP in their own biomedical centers.

General Description
NLP identifies and extracts information from unstructured free text and converts it into a structured form for further use by medical researchers and providers. Multiple studies have demonstrated that this method of data extraction can effectively work with both clinical research and care, which has led to an increased interest in employing this approach to address other medical issues. Selected examples of successful demonstrations include extraction of medication for visualization and reconciliation,¹ screening for patients suffering from traumatic injuries,² identification of post-operative complications,³ detection of signs of infection and cases of influenza for use in biosurveillance,⁴,⁵ quantitation of the use of evidence-based psychotherapy for treating post-traumatic stress disorder patients within the Department of Veterans Affairs,⁶ extraction of clinical decision support information from research reports included within the PubMed database,⁷ detection of patients for colorectal cancer screening,⁸,⁹ and determination of the efficacy of using influenza vaccines to prevent pneumonia.¹⁰ Despite evidence demonstrating the potential benefits of using NLP, medical personnel have, to date, rarely employed this approach to address medical problems or improve patient care.¹¹ Researchers and clinicians interested in using NLP may be hesitant to advocate for its implementation without having the knowledge needed to assess utility and feasibility. The goals of this panel will be to provide that knowledge and to encourage a dialogue between NLP system developers and potential users in order to identify and address barriers to NLP system use. The panel will consist of 4 panel members and a moderator, all of whom have direct experience with the process of developing or implementing medical NLP systems. Each panelist will focus on one of the 4 common steps in NLP system development, 1) document selection, 2) annotation, 3) NLP software development and adaptation, or 4) clinical implementation; panel members will describe lessons learned and elucidate the considerations for accomplishing each step and the challenges that may arise. They will also describe and provide handouts with web page links to current and upcoming tools that may assist with the task. By attending these presentations, potential users will gain an understanding of the overall NLP system development workflow. They will also be able to better assess the applicability of NLP to their own clinical problems of interest.

Structure & Discussion Topics
The moderator will first provide a 15 min overview of the motivation for the panel followed by brief descriptions of the 4 key tasks commonly required for developing an NLP system for use in healthcare. Panelists will then spend 15 min focusing on one of the 4 tasks, and presentations will generally include descriptions of the role of the task in NLP system development, panelists’ own experiences including workflows and lessons learned, tools implemented or used, and barriers to task completion. The last 30 min of the presentation will be for questions from the audience and for discussion between the panelists and audience. Topics for discussion include but will not be limited to:
Capabilities of NLP for medical research and care: Potential users need to be aware of both opportunities that NLP provides and also its current limitations. Specific discussion questions include: 1) What are the clinical and research questions that NLP can address? 2) What biomedical research and clinical questions is NLP currently unable to address? 3) What clinical or research questions are best addressed using approaches other than NLP? 4) What do potential and current users view as the greatest barriers to NLP use?

Development and implementation issues: Currently, there are no “turn-key” NLP applications available for addressing non-trivial medical issues. Developing and implementing an NLP system is often a team effort requiring extensive knowledge in computer science, linguistics, information technology, and implementation science in addition to clinical expertise. Given this current state of clinical NLP, questions to be addressed include: 1) How are the time and expertise requirements for developing and implementing a NLP system estimated? 2) What are the requirements and challenges for completing each of the four steps typically required when developing an NLP system? 3) What do current and potential users see as the major barriers to developing NLP systems for healthcare? 4) Will there ever be “user-friendly” NLP tools developed for use by non-experts?

NLP opportunities: The increase in computer processing speed and infrastructure over the past 10-20 years has increased the feasibility of using NLP to address medical questions, but there appears to be substantial room for growth in its use. Multiple clinical issues that might be helped by the use of NLP represent opportunities for investigation but remain unaddressed. Furthermore, the nature of medical free text may present unique NLP challenges. Questions for discussion with respect to clinical opportunities and NLP challenges include: 1) What NLP challenges are particular to healthcare? 2) What opportunities are there for extending the utility of NLP in healthcare? 3) What clinical questions might particularly benefit from the use of NLP?

Anticipated Audience & Importance of the Topic
This panel should be of particular interest to 1) those intrigued by the promising results generated using NLP but who have a limited understanding of its potential and limitations as well as the full system development process, 2) those interested in tools and workflows that can assist with the development of an NLP system for use in health research or clinical care, and 3) current NLP system users and developers who can share their own experience with barriers to use and would like to learn about the hurdles experienced by potential NLP users in the audience. This topic is timely in that we appear to be at a tipping point with respect to expanding the utility of NLP; a key barrier to its use is not so much its ability to extract useful information but rather getting the techniques and tools into the hands of potential users. Each of the panelists has experience developing and implementing NLP systems for medical research and clinical care. They will share their experiences and describe the tools and workflows they have used in the process, which will provide audience members with the knowledge needed to assess the feasibility and requirements for NLP system development and implementation.

Brief Description of Panelists & Presentations
Dezon Finch, PhD is a health science specialist at the HSR&D/RR&D Center of Innovation in Disability and Rehabilitation Research VISN 8 (CINDRR). Dr. Finch’s research interests include use of statistical approaches to text-mining of medical datasets and ontology generation, using machine learning to detect semi-structured text elements and sections in medical progress notes, and using information extraction for evaluating quality of care. He has served as an investigator within the VA Consortium on Health Informatics Research (CHIR) developing ontologies and schemas for signs and symptoms of post-traumatic stress disorder. He is currently a co-investigator on two VA Investigator Initiated Research (IIR) projects that use NLP; one to determine risk factors for the development of pressure ulcers following spinal cord injury and another to evaluate the quality of pain reassessments in primary care settings. He was PI on a recently completed study that used NLP to evaluate adherence to treatment protocols for veterans with TBI symptoms. His presentation will focus on the issues to consider when selecting clinical documents for developing an NLP system and describe his own experiences and approaches used in completing this task.

Ruth Reeves, PhD Ruth Reeves, PhD is a health services research scientist at the Tennessee Valley Health System VA and an assistant professor in the Department of Biomedical Informatics at Vanderbilt University. She is currently principal investigator on a nationally funded merit award which deploys NLP methodology to temporal reasoning within the electronic health records of veterans suffering from PTSD and is a co-investigator on six nationally-funded projects focusing on the development of NLP systems for clinical use. Dr. Reeves will present and facilitate discussion of the tasks involved in setting up an annotation task and successfully obtaining high quality annotations that meet the needs of the NLP development process. This includes matching annotator domain of expertise with the subject matter of information extraction, annotator training, best practices for resolving annotation disagreements, prioritizing annotation tasks in terms of anticipated information consumption. Her presentation will go thru a typical workflow cycle for an annotation project to illustrate these and other operational considerations.
**Wendy W. Chapman, PhD** is the chair of the University of Utah Department of Biomedical Informatics. Her research focuses on developing and disseminating resources for modeling and understanding information described in narrative clinical reports. She is interested not only in better algorithms for extracting information out of clinical text through NLP but also in generating resources for improving the NLP development process (such as shareable annotations and open source toolkits) and in developing user applications to help non-NLP experts apply NLP in informatics-based tasks like clinical research and decision support. In this panel, Dr. Chapman will describe the steps required in creating an NLP tool for a targeted task. With a real-life use case, she will discuss the types of tools and resources that are available to create or customize an NLP tool, including knowledge resources, NLP pipelines and tools, and evaluation tools.

**Jennifer H. Garvin, MBA, PhD** is a research health scientist within the VA Salt Lake City Health Care System and associate professor at the University of Utah. Dr. Garvin’s research interests include automated quality measurement, stakeholder engagement for requirements gathering and applied uses of NLP. She has professional training and research experience in terminologies, classifications, healthcare standards, implementation science methods and NLP. Dr. Garvin is currently the principal investigator on a project that will use NLP to improve post-CHF discharge beta blocker titration, according to the guideline-recommended care, and thereby reduce hospital readmissions and improve patient outcomes, and she is a co-investigator on three additional nationally-funded research projects involving the clinical use of NLP for information extraction. Dr. Garvin will share her experience and the workflow she has used in developing and implementing NLP systems for clinical use.

**Glenn T. Gobbel, DVM, PhD, MS** will moderate the panel, and he is a research assistant professor in Health Services Research at the Tennessee Valley Health System and within the Department of Biomedical Informatics at Vanderbilt University. His current research interests are the generation of algorithms that improve the performance and enhance the clinical utility as well as development of applications to assist in the development of NLP system. His work has focused on the development of near-real time NLP tools for extraction of medical information from free text and machine-learning based tools that rely on online learning for assisted annotation. He is currently a co-investigator on six nationally-funded projects focusing on the development of NLP systems for clinical use.

**Participation Statement:** All proposed panelists have agreed to participate in the panel.

Didactic Panel
Natural Language Processing for Phenotype Extraction: Challenges in Extraction and Representation

Guergana Savova, PhD¹, Rebecca Jacobson, MD, MS², Joshua Denny, MD, MS³, Nicole Washington, PhD⁴, Harry Hochheiser, PhD²

¹Children’s Hospital Boston, Boston, MA; ²University of Pittsburgh, Pittsburgh, PA; ³Vanderbilt University, Nashville, TN; ⁴Lawrence Berkeley National Labs, Berkeley, CA

Abstract

Previous work has demonstrated the benefits of using Natural Language Processing (NLP) techniques for extracting diagnoses from clinical texts and assigning patients to categories for cohort identification and GWAS studies using electronic health record (EHR) data. However, there is a growing awareness that understanding cancers and other complex or rare diseases will require richer phenotypic models that describe the development, progression, and location of specific signs and symptoms. Computing over these “deep phenotypes” will require NLP methods that can interpret individual documents, summarization approaches that can combine information from multiple notes and document types (e.g., radiology, pathology, and clinical notes) to build a longitudinal patient, and structured data models that will facilitate the integration between NLP and existing discrete data and comparison of these phenotypic models. This panel will discuss challenges inherent in developing both data models and the NLP tools. Strategies involving the use of NLP pipelines (cTAKES), clinical data models (FHIR), and phenotype data exchange formats will be discussed. Attendees will gain an understanding of the NLP challenges in extracting deep phenotype information, strategies for representing phenotype data, and emerging systems and tools that are applying these techniques to challenging translational problems.

Description

This panel will provide multiple perspectives on the challenges of using Natural Language Processing to extract detailed phenotype models from clinical texts. Presentations will cover technical issues including NLP pipelines and phenotypic models, experience in application to specific diseases, and translational linkage to genomics. This breadth of discussion will provide participants with an understanding of the current landscape and an appreciation for the potential benefits of combining NLP with principled phenotype modeling:

• Geurgana Savova, project lead for the widely used cTAKES NLP pipeline, will discuss new developments and current efforts in extending the capabilities of NLP tools.
• Rebecca Jacobson will present an overview of the overall landscape and perspectives from the application of NLP and phenotyping to cancer informatics.
• Joshua Denny will describe lessons learned from eMERGE and other large-scale phenotyping projects integrating NLP with other data across the EHR.
• Nicole Washington will introduce translational applications for structured phenotype descriptions.
• Harry Hochheiser will discuss issues involved in data models for phenotype representation.

Need

• Clinical NLP continues to grow in importance
• Characterizations based on simple categorization are not sufficiently nuanced for translational research of complex diseases
• Models of computing over complex phenotypic descriptions are nascent and barely emerging. Specifically:
  • Although temporal models exist, relatively little work has been done in using NLP to interpret complex descriptions of patient state over time.
o Building longitudinal models of patient histories requires summarization logic not found in many NLP pipelines
o Construction of high-level overall patient phenotypes models that can be exchanged and integrated across contexts
o Although integration with clinical data models might be beneficial, models such as FHIR are not yet widely adopted.

Clinical and translational researchers working in these areas currently face significant challenges in identifying and evaluating appropriate tools and data models. This panel will provide a variety of perspectives that will help participants better understand how to engage in NLP-based phenotyping efforts.

**Audience**
- Clinical researchers interested in extracting structured phenotypes from EMR data.
- NLP developers working on new techniques for addressing challenges in interpreting clinical text.
- Participants in PCORNet or other efforts aimed at aligning phenotype data from multiple diverse sources.
- Translational researchers searching for model systems for human diseases.

**Discussion Questions**
- What level of detail is required in NLP, summarization, and exchange models of phenotypes?
- How can models be effectively validated?
- How does data extracted via NLP compare with structured data for phenotype sensitivity, precision, and granularity?
- How do variations in care across institutions/contexts impact the generalizability of these models?
- How can summarization logic be expressed in some computable form?
- What are the advantages and disadvantages of using OWL representations? FHIR?
- How can the tradeoffs between consistency of models and flexibility for adaptation be best balanced?

**Participants’ Assent**

All participants have agreed to take part on the panel.
Needs of the Digital Native:

Adolescents and Access to PHRs

Catherine Arnott Smith, AMLS, MA, MSIS, PhD
Fabienne Bourgeois, MD, MPH
Pamela Charney, MS, MS, PhD

1University of Wisconsin-Madison, Madison, WI; 2Boston Children’s Hospital, Boston, MA; 3Bellevue College, Bellevue, WA

Moderator: Patricia Flatley Brennan, RN, PhD, FAAN, FACMI

Abstract

PHRs present particular challenges in pediatrics and the pediatric PHR is a particularly timely, while controversial, issue in medical informatics. This is true because minor patients present “unique health privacy and confidentiality standards,” different users within a family unit have different rights to access different information, and there are “extensive variations” in PHR implementation and access across the United States. This panel considers the challenges, benefits and risks of access to PHRs by adolescent patients. In order to address the needs of this population, we have to support access policies that handle age-specific changes in PHR ownership, as well as encourage EHR functionality that allows appropriate identification and classification of confidential information. We also offer two examples of how these challenges play out in context of adolescents’ lived experiences. How is care coordinated for adolescents with chronic health conditions when PHRs are not available? Can PHRs play a role in assisting adolescents and young adults living with chronic illness to develop self-advocacy and self-awareness?

Barriers to PHR Access

Personal health records (PHRs) have been defined as “collections of health or wellness data arising from multiple sources about an individual’s health … managed, controlled or shared by that individual or designate.” These can be paper-based or electronic systems. PHRs’ information management functions include reporting immunization data, laboratory test results, visit summaries, and problem lists. They have received increased attention from biomedical informatics as increasing amounts of health data become available in EHRs to which PHRs can be tethered. For this reason, PHR growth parallels that of EHRs.

The potential of PHRs for recordkeeping by families, beyond the individual, has been formally investigated since 1964. In the 21st century, use of PHRs in pediatrics presents a complicated situation for communication and information-sharing alike. First, pediatrics has “lagged behind other specialties” in using electronic tools, and few PHR systems have been developed. Second, in pediatric practice, patients occur in dyads and triads. Parents are the first responders, primary communicators, and information managers for their children. Bourgeois, Taylor, Emans, Nigrin & Mandl have written of the challenges these facts of life pose for PHR development: minors present “unique health privacy and confidentiality standards,” different users have different rights to access different information, and there are “extensive variations” across states and localities in the US.

Panel Description

This panel begins with presentation of the challenges, benefits and risks of access to PHRs by adolescent patients. We then present two examples of how these challenges play out in context of lived experiences: first, the management of chronic illness without a PHR; second, the acquisition of self-advocacy skills for negotiating academic accommodations in the high school and future college classroom.

Patricia Flatley Brennan, RN, PhD, will serve as moderator for the panel. Dr Brennan is the Lillian L. Moehlman Bascom Professor, School of Nursing and College of Engineering, University of Wisconsin-Madison, Madison, Wisconsin. She developed the ComputerLink, an electronic network designed to reduce isolation and improve self-care among home care patients and directed HeartCare, a WWW-based tailored information and communication
service that helped home-dwelling cardiac patients recover faster, and with fewer symptoms. Dr. Brennan directed Project HealthDesign, a RWJ-funded initiative designed to stimulate the next generation of personal health records. Brennan leads the Living Environments Laboratory at the Wisconsin Institutes for Discovery, which includes a 6-sided virtual reality CAVE that her group uses to re-create visually every environment on earth, and develop new ways for effective visualization of high dimensional data. Supported by AHRQ, her vizHOME group explores the impact of household contexts on personal health information management.

Fabienne Bourgeois is a Pediatric Hospitalist and Clinical Informaticist at Boston Children's Hospital. As the Medical Director of Patient-Facing applications, she has helped develop and implement a patient portal specifically designed to meet the needs of a pediatric and adolescent population.

Pamela Charney is a former practicing registered dietitian specializing in pediatrics and clinical care. Her previous research focused on nutrition-related issues ranging from development of a pediatric nutrition center of excellence to evaluating nutrition status of underserved groups who receive home care. She is currently collaborating with the Informatics Consortium at Bellevue College as part of their $12 million DoL project and has another project in development investigating health outcomes associated with technology use by adolescents with chronic health conditions and their caregivers.

Catherine Arnott Smith is an Associate Professor at the School of Library & Information Studies, University of Wisconsin-Madison. Her research interests and publications center on consumer interactions with clinical information systems through text, particularly consumer health vocabulary, and in domains ranging from electronic medical records to public libraries.

All participants have agreed to take part in the panel.

BOURGEIOS

Adolescent patients rarely have full control of their personal health records (PHRs), instead relying on parents and guardians to share control. This shared access necessarily changes over time, as a result of developmental and age-appropriate considerations, as well as guardianship arrangements. In particular, once a patient reaches the age of majority (generally at age 18 years in most states), the patient becomes the sole guardian of the PHR. However, the transitioning adult’s readiness to assume this new role, in part, depends on her prior experience and access to a PHR.

Most current PHR ventures either limit access to the application or restrict the available information in the adolescent PHR due to the unique ethical and legal challenges experienced by this population. The greatest difficulty involves protecting the adolescent’s legal right to privacy and confidentiality within a shared access model. Many medical encounters with adolescents come with assurances that what they report will remain entirely confidential, so that personal health information pertaining to reproductive health, sexually transmitted illnesses, substance abuse and mental health will not be communicated to their parents without their consent. Similarly, parents may share information with the expectation of privacy and do not want the information shared with the adolescent. As it turns out, these types of confidential information are pervasive throughout most patients’ electronic health records (EHRs).

In order to address the needs of the adolescent population we have to support access policies that handle age-specific changes in PHR ownership, as well as encourage EHR functionality that allows appropriate identification and classification of confidential information.

This discussion will focus on the options for shared access models for adolescent PHRs (along with their respective benefits and risks), as well as handling of medical content in the EHR requiring special consideration to minimize inadvertent disclosures through the PHR.

CHARNEY

Use of pediatric personal health records (PHR) facilitates management of chronic illness in childhood. However, because of challenges associated with privacy and security of adolescent health information many healthcare organizations severely limit access to personal health records (PHR) for adolescent patients. Therefore, families caring for adolescents with chronic illness often lose access to the benefits of using their child’s PHR. Lack of access to the PHR has significant consequences including poor care coordination, duplication of tests, and poor communication.

Some healthcare organizations do allow parents limited access to their adolescent’s PHR, particularly for secure messaging with providers and appointment scheduling. When even limited access is not available, parents/caregivers of adolescents with chronic illness are forced to spend significant time coordinating care.
The situation is made even more complex when care is provided through more than one healthcare organization, each of which may have different policies regarding access to adolescent health information.

This presentation will focus on the challenges associated with coordinating care for adolescents with chronic health conditions when PHRs are not available and offer suggestions for improving access while maintaining appropriate privacy for the adolescent.

SMITH

PHRs seem to have a motivational effect on patients to serve as monitors of their own health data, from diabetes passports to Project Health Design. People living with chronic illnesses are more likely than others to maintain “summaries of their health histories, medications, and physician names” and this translates to a high interest in using PHRs—these people were found in one study to be 25% more likely to adopt these technologies.

Adolescents living with chronic illness are thus an important potential audience for PHR technologies. These heavy users of technology are transitioning into adulthood not only in the clinic, but in the classroom. The academic accommodation process for students with disabilities, like the Social Security Disability Insurance system described by Lytle-Kosola et al., uses health information as “a primary input to facilitate movement.”

The speaker agrees, with Lytle-Kosola et al., that consumer health IT can used to reduce the “information-gathering” burden for student clients. This is a population very likely to benefit from early familiarity with PHRs. When we shut out, or partially restrict, adolescent patients’ use of PHRs we create a knowledge burden and a resource challenge for the newly emerging adult they are engaged in becoming. This presentation will use examples from an ongoing research study to illustrate the role of clinical documentation in young adults’ self-advocacy and self-awareness around disability and academic accommodations.

Expected Discussion

Panel attendees will be encouraged to share their opinions and experiences. The goal is to discuss the feasibility of possible solutions to the challenges outlined in the panel presentations, and to contribute to ideas for a medical informatics research agenda moving forward.

Abstract

In response to the large West African Ebola outbreak beginning in 2014, Ebola Treatment Centres (ETCs) were established to provide efficient care for suspected and confirmed Ebola patients while minimizing risk of cross infection to staff and other patients. Critical clinical information entry and review tasks such as assessments, ordering, and administration of drugs and fluids must be performed rapidly in highly challenging conditions because workers wear personal protective equipment (PPE) which reduces dexterity, vision and comfort. Additionally, it is vital to have information tools to conduct important functions, such as contact tracing to limit the spread of new cases and trials of new diagnostic/therapeutic approaches.

In this panel, members of two teams providing rapid development and implementation at different centres describe the unique situational needs and challenges, software and hardware considerations and solutions, user engagement throughout testing and rollout, and approaches to advanced functionality such as analytics and clinical decision support. The audience will be better able to plan future implementations in challenging environments; to include information management in advance planning for future crises; and should be able to leverage available technologies and strategies for effective design and deployment of crisis information systems.

Panel Description

The 2014 West African Ebola outbreak is unprecedented in its scale and spread, with over 24,000 suspected or confirmed cases and over 10,000 deaths through mid-March 2015. In response to the outbreak, Ebola Treatment Centres (ETCs) have been established; these specialized facilities must provide efficient care for suspected and confirmed Ebola patients while minimizing risk of transmission of disease to staff and other patients\textsuperscript{1}.

As with any medical facility, ETC operation involves information-intensive tasks, including registration and admission; frequent patient status assessment, recording and reviewing; ordering, dispensing and administration of medications, fluids, and blood products; ordering and reporting of a limited number of laboratory tests. Due to the focus on epidemic-scale infectious disease, tracing of contacts of each patient is also critical. Because optimal treatment for Ebola is not completely established and new treatments are under development, it is also important to capture information about status, treatments and outcomes in order to improve care in the future.

Many of these information tasks must be performed in the “red zone” where patients with suspected or confirmed Ebola are located. The red zone presents several challenges to all operations, including the difficulty of working in personal protective equipment (PPE) which significantly limits visual resolution and dexterity and also limits available time in the zone due to its discomfort. Since materials in the red zone are considered contaminated, they cannot be transferred out into the “green zone”; thus paper recording is not an option even if it were otherwise satisfactory. Moreover, electronic data recording is essential for proper documentation and communication, and especially for data collection, surveillance and research to improve care. The user interfaces of typical EMR applications and data collection tools, though, are difficult or impossible to use in the red zone environment. Innovative design and development is required to permit quick, usable, comprehensive information recording and review. In addition, innovative hardware and infrastructure design may be needed due to other environmental issues.
A number of organizations have risen to the challenge, rapidly developing and implementing Eb
l systems and tracking systems for ET
cs. One of these ET
cs was established at Kerry Town, outside of Freetown, 
Sierra Leone, under the auspices of Save the Children International; the development team included staff from 
Thoughtworks as well as several additional members of the OpenMRS community. At this centre, the team has 
deployed a novel interactive EMR with a wide range of administrative and clinical functions for green and red zone 
operation, using a tablet-based user interface suitable for PPE use with large text and touch targets, minimal typing, 
a high-contrast colour scheme, and functional design for rapid and easy operation with this interface. Other 
treatment centres have been established under the auspices of Médecins Sans Frontières; this team developed a 
system, also on an OpenMRS base, with assistance from a development team at Google Inc. It has placed 
additional emphasis on clinical trials management, mobile apps for contact tracing and epidemiology, and 
infrastructure advances such as resilient power, mesh networking and solvent-resistant casings.

A critical success factor in the deployment of these systems is working with the local healthcare team and leadership on workflow, implementation planning, and iterative system acceptance. The implementation leaders from the 
informatics teams had extensive discussions with all clinician roles, epidemiologists, programmers/developers, researchers, IT/connectivity staff, hygiene/infection control staff, and other organizations involved in the response. Such discussions were and need to be a continuous, rather than one-off, process given the dynamic nature of emergencies. In these conversations, important system requirements were conveyed, such as the need for 
waterproof tablet PCs and the real, most important everyday information elements. They also revealed what subset of functions constituted a minimum viable product (MVP) for the system, so that key modules could be rolled out 
rapidly and additional ones layered on as they were developed. Continuous feedback and interaction with 
physicians, nurses, pharmacists, and others has been vital to the ongoing success and value of these systems.

In this panel, leaders from these different efforts explore the practical challenges, design and deployment 
innovations, implementation strategies, rollout experience, real achievements and ongoing issues from these efforts. 
The panelists will discuss lessons learned in the process that can make it possible to be more prepared for, and more responsive to, crises yet to come.

**Participants**

**Jonathan Teich, MD, PhD, FACMI** will moderate the panel and discuss functional design considerations, 
optimization of speed and usability for specialized care settings, and clinical decision support (CDS) opportunities, 
based on practical clinical considerations as well as informatics principles. Dr. Teich has over 20 years of experience 
in EMR design, CDS and rapid access to medical knowledge, working in academic, provider, industry and 
government settings; he is a practicing emergency physician and has studied and written on disaster and crisis 
informatics since 2001.

**Hamish Fraser, MBChB, MSC, FACMI** will discuss the wider information needs of disaster management, 
resource and supply chain management, and working with local and national leaders. He will also discuss evaluation 
and research to ensure effective and usable systems that work even in crisis situations, and how all the organizations 
doing crisis response work can collaborate further on these eHealth systems and implementation strategies. Dr. 
Fraser has worked for over a decade to bring medical informatics tools and expertise from developed countries to 
some of the most challenging environments in the developing world, and is currently working to develop a 
framework and strategies for evaluation of these tools worldwide.

**Eric Peraklis, PhD** will discuss needs assessment, systems selection and similarities and differences of the various 
platforms and available options to provide needed capability, with a particular focus on contact tracing, research and 
infrastructure at the MSF treatment centres. Dr. Peraklis is an informatics and R&D leader with a background 
ranging from pharmaceutical discovery to cybersecurity to bioinformatics. He serves as executive director of the 
Center for Biomedical Informatics at Harvard Medical School, and has had leadership positions at the FDA and at 
Johnson & Johnson.

**Shefali Oza, MSc** will discuss the requirements for efficiently implementing technology-based solutions during a 
disaster. Besides the software and hardware, successful implementation requires planning, management, training, 
continuous feedback, and a staged rollout, all of which present unique challenges during complex humanitarian 
emergencies; she will discuss these issues in the context of this Ebola EMR deployment. Ms. Oza is an 
epidemiologist at the London School of Hygiene and Tropical Medicine and has worked on global health projects in 
five continents.
Darius Jazayeri, MEng, will discuss the software, system infrastructure, development and maintenance considerations of the functional modules as well as the OpenMRS platform that underlies both of these projects. He is a Principal Architect with the Global Health team at ThoughtWorks, Inc, and a Software Developer with the Medical Informatics team at Partners In Health. He has built eHealth systems for developing countries for 15 years, including clinical data capture, drug order entry, reporting, analytics, and more. He is a lead developer of the OpenMRS open source medical record platform, where he is responsible for the architecture of its reference application, and helps coordinate contributions from developers worldwide.

Importance to the Audience

This panel is clearly urgent and timely; Ebola was a ferocious killer in 2014 and while the numbers are reduced as of this writing, the epidemic is certainly not over, and could flare up again. Moreover, we can be sadly confident that more epidemics, disasters and health crises will occur over time. Information technology is clearly a vital part of the effort to halt these rampages, and it just as clearly requires new ways of thinking in design and implementation, particularly when the crisis requires hazardous or difficult working conditions.

Because there will be more crises, we should pay attention now to shared lessons, common core infrastructure, necessary modular functions and readiness planning, so that the time from the start of the next crisis to the implementation of usable and valuable information tools can be much shorter. The panel will bring new ideas and show the way to new shared efforts that can be started now. In addition, the audience will gain additional motivation and strategies for including research and epidemiology in any project so that care can improve.

Even beyond any health crisis, the innovations developed in Africa may have implications for informatics and system design everywhere. In the process of developing easier systems for difficult environments, the teams have found techniques that lead to faster and easier systems in general. Lessons learned from the Ebola work can be applied now to better daily-use EMRs in “normal” environments.

The target audience includes system designers, implementation leaders, CMIOs and CNIOs, global health leaders, health services researchers, students and anyone who is interested in what has been done to combat this lethal epidemic.

Discussion Questions

1. How do you work with the local governments and health bodies to ensure success?
2. How can you ensure robust maintenance, support and necessary system enhancements?
3. How can we collaborate to harmonize these and other efforts, to share strategies and toolkits, and in general to make these innovations more widely and available?
4. What types of research are most valuable while simultaneously practical and achievable in these situations?
5. What other new devices, technologies, designs or strategies may be useful to address the challenges?
6. What can we do to have a quicker, better response to the next crisis?

Panel Organizer’s Statement

All participants have contributed to the proposal and agree to take part on the panel.

State of the Art of Clinical Narrative Report De-Identification and Its Future

Peter Szolovits, PhD, 1 John Aberdeen, MA, MS, 2 Stephane Meystre, MD, PhD, 3,4 Mehmet Kayaalp, MD, PhD 5

1Massachusetts Institute of Technology, Cambridge, MA; 2MITRE Corporation, Bedford, MA; 3University of Utah, Salt Lake City, UT; 4VA Health System, Salt Lake City, UT; 5National Library of Medicine, Bethesda, MD

Abstract

While automatic de-identification systems exist, release of de-identified data usually requires significant multi-round expensive effort for validation. To overcome this barrier, we need a consensus on the parameters of successful automatic de-identification. Although we can establish such parameters relative to error rates of human annotators, it is ultimately a policy question whose answer needs to be vetted by the public.

When personal identifiers are substituted with surrogates or pseudonyms, it could be very difficult to spot the residual identifiers missed by the de-identifier, but in absolute terms, it is difficult to ensure that de-identified clinical text contains no references that might indirectly identify the patient; hence, de-identified clinical text is usually shared through a data use agreement. When such an agreement is in place, dates and some address parts can be left identified in a limited data set. If we reframe the de-identification problem by focusing on the pertinent identifiers, we may smooth the path to data sharing.

Installing and running a clinical de-identification system may require substantial expertise, which small institutions and clinical scientists may lack. Although we would like to develop capable systems with sophisticated functionalities, we also should strive for simplicity for routine de-identification tasks.

Audience

- Clinical scientists
- Clinical practitioners
- Clinical informaticians
- Clinical application developers
- Policy makers in health institutes

Questions

1. How can we reach out to policy makers to establish parameters of successful automatic de-identification?
2. How should we approach the public, explain the importance of the availability of de-identified clinical narrative reports for the advancement of clinical sciences, and win the public trust?
3. How can we ensure the integrity of information, when we pseudonymize de-identified text? What should be the safety margins?
4. Can de-identification be provided as an online service? If so, how can we solve the trust issue and overcome institutional barriers?
5. How can we reach out to clinical institutions and convince clinicians not to use personal identifiers in their clinical reports?
Why the topic of this panel is timely and/or controversial

Clinical text de-identification (CTD) is no longer a dream. It is an increasingly important practical tool for making clinical text data available to a wider clinical research community. This panel will discuss a number of hot topics surrounding CTD. There is no default answer to any of those questions. Many of those issues are quite controversial. For example, CTD as an online service is an attractive but untested idea and it could be the only practical solution for many small institutions with limited expertise in informatics.

Information about panelists and their topics of discussion

Peter Szolovits is Professor of Computer Science and Engineering in the MIT Department of Electrical Engineering and Computer Science (EECS) and an Associate faculty member in the MIT Institute of Medical Engineering and Science (IMES) and its Harvard/MIT Health Sciences and Technology (HST) program. He is also head of the Clinical Decision-Making Group within the MIT Computer Science and Artificial Intelligence Laboratory (CSAIL). His research centers on the application of AI methods to problems of medical decision making, natural language processing to extract meaningful data from clinical narratives to support translational medicine, and the design of information systems for health care institutions and patients. He has been a founder of and consultant for several companies that apply AI to problems of commercial interest. He received his bachelor's degree in physics and his PhD in information science, both from Caltech. Prof. Szolovits was elected to the Institute of Medicine (now the National Academy of Medicine) and is a Fellow of the American Association for Artificial Intelligence, the American College of Medical Informatics and the American Institute for Medical and Biological Engineering. He recently served as a member of the National Research Council's Computer Science and Telecommunications Board and is a member of the National Library of Medicine’s Biomedical Library and Informatics Review Committee. He is the 2013 recipient of the Morris F. Collen Award of Excellence from the American College of Medical Informatics.

Making clinical data available for research is an absolute necessity for improving our understanding of disease and raising the quality of decisions in health care. However, that benefit is offset by risks to confidentiality of patient data. Stripping or replacing explicit identifiers such as names, medical record numbers, addresses and the other HIPAA-specified data elements is straightforward, but de-identifying narrative reports accurately would require automated procedures almost to understand the content of those reports. Automated de-identification tools have taken several main approaches to protect confidentiality without sacrificing too much of the value of the narrative data. Rule-and-dictionary based methods can identify both specific elements that are to be elided (e.g., names) and elements that are to be retained (e.g., medications), but can err on out-of-vocabulary elements. Machine learning methods require substantial training on annotated data and need retraining when applied to new data sets where stylistic and linguistic conventions may differ. Synthesis techniques model the distributions and relationships among data elements and synthesize new data sets with similar characteristics, which assure that no actual data can leak; but they support well only those analyses that rely on the same retained characteristics. Differential privacy, thus far mostly applied to coded rather than narrative data, may provide another approach, but tends to destroy much data in order to maintain its confidentiality guarantees. The choice of the “best” techniques to apply are probably application dependent.

John Aberdeen is the project leader for the open-source MITRE Identification Scrubber Toolkit (MIST), which provides an environment to support rapid tailoring of automated de-identification to different record types, using automatically learned classifiers. He will discuss recent research about the replacements used when de-identifying clinical notes, and how careful surrogate generation can render de-identified notes more resistant to re-identification attacks.

In contrast to rule-based systems, de-identification via trained classifiers provides a clean separation between a clinician’s domain knowledge (applied when generating training data for the classifiers), and the software that
applies that knowledge. All de-identification processes, when manual or automated, leave behind some (often small) number of un-redacted PHI elements (residual PHI), with an associated risk of exposure. Rather than attempting in vain to make tiny incremental improvements to eliminate residual PHI, we can accept that de-identification is imperfect, and carefully choose PHI replacements that blend smoothly in with the surrounding text. If we do this well, the residual PHI become extremely difficult to detect (hiding in plain sight), and cannot be used to launch a re-identification attack.

**Stéphane Meystre** is faculty member of the Department of Biomedical Informatics at the University of Utah with research activities focused on easing access to clinical data for research and clinical care purposes, using techniques such as Natural Language Processing for information extraction and automated de-identification, and automating ontologies development and management.

The U.S. Department of Veteran’s Affairs (VA) is funding an informatics initiative called the Consortium for Healthcare Informatics Research (CHIR), focused on utilizing both structured and unstructured data previously unavailable for research and operational purposes. Evaluating existing de-identification methods and building and evaluating new methods and tools is one of the cornerstones of this initiative, and will be presented during this panel. Realized efforts shall fulfill the ethical and legal obligations of patient privacy and confidentiality.

Dr. Meystre is leading the CHIR de-identification project, building a best-of-breed de-identification system for VA clinical documents, evaluating its interaction with subsequent text processing, and eventually how anonymous de-identified documents are. He will first introduce the audience to the best-of-breed system developed for VA clinical text, and share issues related with text de-identification. He will then present generalizability and adaptation to VA text difficulties.

**Mehmet Kayaalp** is the organizer of the panel. He graduated from University of Istanbul with an M.D. degree, from Southern Methodist University with an M.S. degree in Computer Science and from University of Pittsburgh with a Ph.D. degree in Intelligent Systems. Since 2003, he is in public service working at the National Library of Medicine as staff scientist. He currently leads there the NLM Scrubber project. NLM Scrubber is a clinical text de-identification system, freely available at [https://scrubber.nlm.nih.gov](https://scrubber.nlm.nih.gov).

Mehmet will discuss various aspects of the following questions:

- Is there a better way to generate de-identified data? Downloading and running stand-alone clinical text de-identification applications is the current standard for sharing. What other options are there? How feasible is it to distribute large-scale de-identified clinical text data? Would small clinical research institutes be open to de-identify their clinical reports through an online service?
- Can we go beyond the token-based precision and recall metrics to measure the actual performance of a de-identification system? What are the problems of the current evaluation approaches and how can we remedy those?
- Should we redefine our goals of success, re-prioritize the de-identification tasks at hand, and focus on the personal identifiers that need to be de-identified in limited data sets?

All participants have agreed to take part on the panel.
Informatics Research and Innovation in a Commercial Electronic Health Record:
The Experience of Three Organizations Using Epic
Organizer: Adam Wright, PhD

Panelists:
Adam Wright, PhD a,b,c
David W. Bates, MD, MS a,b,c
Eric S. Kirkendall, MD, MBI d,e
David A. Dorr, MD, MS f
Peter DeVault, MS g

Panelist Affiliations:
a Partners Healthcare System, Boston, MA
b Brigham & Women’s Hospital, Boston, MA
c Harvard Medical School, Boston, MA
d Cincinnati Children’s Hospital Medical Center, Cincinnati, OH
e University of Cincinnati, Cincinnati, OH
f Oregon Health & Science University, Portland, OR
g Epic Systems, Verona, WI

Abstract: (150-200 words)
Historically, many of the key innovations in informatics came from organizations with self-developed clinical information systems. Having a self-developed system gives organizations considerable flexibility to tailor and extend their software and explore new and potentially innovative approaches. However, maintaining a self-developed system is expensive, poses risks to generalizability and makes scaling challenging. Recognizing these issues, most academic medical centers have moved, or are in the process of moving, to commercial electronic health records (EHRs).

In this panel, we present the experience of three organizations which are actively implementing innovative approaches to improve care: Partners HealthCare, Cincinnati Children’s Hospital Medical Center and Oregon Health and Science University. All three organizations, at one time, had pioneering self-developed systems but switched to Epic, one of the most popular EHRs used worldwide.

The presenters will detail their organizations’ experience innovating on the Epic platform through the lens of several case studies, introduce the range of technical approaches for developing and integrating innovative tools in Epic, discuss Epic’s approaches to working with innovators and cover issues in organization governance of innovation activities.

Though the focus of the panel is the experience with Epic, the lessons learned apply to all commercial EHRs.
Description:
The overall outline of the talk is given in the abstract. The panel will be organized as follows:

<table>
<thead>
<tr>
<th>Time</th>
<th>Speaker</th>
<th>Topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 min</td>
<td>Wright</td>
<td>Introduction, overview of innovation in self-developed and commercial systems</td>

<tr>
<td>10 min</td>
<td>Bates</td>
<td>Lessons learned and innovation governance</td>
</tr>
<tr>
<td>30 min</td>
<td>Panel</td>
<td>Discussion and questions from audience</td>
</tr>
</tbody>
</table>

The specific topics covered by each presenter will be:

1. Wright (introduction): Introduce the topic and panelists, including a brief description of what each panelist will be talking about and their affiliations. Provide an overview of the history of informatics innovation in self-developed systems and the challenges and opportunities of innovation in commercial systems.
2. Wright (overview and Partners experience): Give an overview of the modes of integration for innovations in Epic, including data extracts, web services, building clinical content, embedding external applications and Open.epic services, including FHIR. Present the Partners experience innovating in Epic.
3. Kirkendall: Give an overview of Cincinnati Children's Hospital Medical Center’s experience innovating in and extending Epic, including challenges and lessons learned.
4. Dorr: Give an overview of OHSU’s experience innovating in and extending Epic, including challenges and lessons learned. Dr. Dorr’s presentation will be coordinated with Dr. Kirkendall’s presentation to ensure they do not overlap.
5. DeVault: Give an overview of Epic’s resources for innovators, including training, certification and support, as well as Epic’s approach to innovation.
6. Bates: Summarize and synthesize the experience of the panelists, the challenges and lessons they encountered along the way, concluding with a vision for approaches to innovation governance that organizations can adopt.
7. Panel: After the presentations, the panel will briefly discuss additional issues and then open for questions from and discussion with the audience. Audience members will be invited to address questions to specific panelists, or to the panel as a whole.

Importance:
As many organizations shift from self-developed EHRs to commercial systems, and many academic institutions have switched to Epic in particular, questions have been raised in a variety of venues about how informatics research and innovation will be able to proceed. Many participants have expressed concern that commercial systems may be inflexible, stifling innovation. However, Epic and other vendors are increasingly supporting a variety of approaches that enable innovation, including additional approaches for customizing clinical decision support and open Application Programming Interfaces (APIs).
In this panel, we outline the experience of three organizations that have successfully innovated in Epic, and also describe the range of approaches for innovation. As organizations continue migrating to commercial systems, we believe it will be essential for the informatics community to engage with commercial systems, and develop best practices and approaches for innovating on commercial platforms. We believe that this panel will be critical to advancing this discussion and providing a roadmap for organizations and individuals looking to innovate on commercial platforms.

Discussion Questions:
1. What tools and processes can EHR vendors provide their customers to enable innovation?
2. What are best practices for encouraging and fostering innovation in clinical organizations?
3. How can organizations develop and employ effective governance approaches for informatics innovation?
4. What are the similarities and differences in informatics research and innovation in self-developed and commercial systems?
5. How can innovations developed at one site be effectively disseminated to other organizations using the same or different software?
6. What were the challenges and lessons learned encountered by the sites as they developed innovation approaches?
7. What are future directions and research and innovation foci for sites using commercial systems?
8. How do you engage and communicate with vendors in regards to innovation?
9. What are the risks and benefits of innovating with vendor software?

Participation statement:
All proposed panelists are aware of this panel submission, and have agreed to participate in the panel if the proposal is accepted.
Challenges, Successes, and Future Directions of Consumer Health IT Evaluation

Uba Backonja, PhD, RN\(^1\) (organizer); Rupa Sheth Valdez, PhD\(^2\) (moderator); William Riley PhD\(^3\), Katie Sick, PhD\(^4\); Teresa Zayas-Cabán, PhD\(^5\); Kenneth Goodman, PhD\(^6\)

\(^1\)School of Medicine, University of Washington, Seattle, WA; \(^2\)Department of Public Health Sciences, University of Virginia, Charlottesville, VA; \(^3\)Science of Research and Technology Branch, National Cancer Institute, Bethesda, MD; \(^4\)Informatics Division, Indiana University, Bloomington, IN; \(^5\)Health IT Portfolio, Agency for Healthcare Research and Quality, Rockville, MD; \(^6\)Bioethics Program, University of Miami, Miami, FL

Abstract

The accelerated growth and diversity of consumer health IT interventions creates an urgent need to develop evaluation criteria and methods to assess their effectiveness and efficacy. This panel will discuss challenges, successes, and future directions of evaluating consumer health IT interventions. Panelists will discuss their evaluation experiences: Dr. Riley will discuss accounting for the rapid pace of technological change; Dr. Siek will discuss accounting for patients’ workflow and daily living contexts; Dr. Zayas-Cabán will discuss accounting for intervention efficacy and safety; Dr. Goodman will discuss accounting for ethical considerations. The session will then serve as a forum for the panelists and audience to discuss topics related to consumer health IT evaluation, such as how to: modify existing knowledge and evaluation frameworks for consumer health IT evaluation; assess the safety and cost/benefit of the interventions; and balance evaluation rigor and richness with the need to efficiently evaluate rapidly changing technologies. This panel is timely given the rapid uptake of consumer health IT technologies, which necessitates the development of new and innovative methods to evaluate these technologies and interventions.

Intended Audience

Individuals who have experience or interest in consumer health IT research and/or intervention evaluation.

Aim of the Discussion

To discuss the challenges of and strategies for evaluating consumer health IT interventions.

Overall Panel Topic

Consumer health technologies and interventions are becoming ubiquitous. However, existing evaluation criteria and methods to assess whether consumer health IT interventions are safe and effective are still in their infancy. For example, only recently (February 2015) did the Food and Drug Administration release revised guidance on its oversight of mobile health (mHealth) applications. Therefore, the purpose of this panel is for panelists to discuss their experiences in consumer health IT evaluation, and to converse with the audience about how to address consumer health IT evaluation challenges.

Contribution of Each Panelist

At the start of the session, each panelist will provide a short presentation about his or her work in consumer health IT evaluation.

William Riley, PhD

Dr. Riley will focus on the need for consumer health IT evaluations to account for the rapid pace of technological change. Consumer technologies change more rapidly than technologies that need to be selected and implemented by organizations, and a similar relatively rapid pace can be expected in consumer health IT. Consequently, evaluation of consumer health IT before, during, and after its adoption by consumers needs to be conducted in a highly timely manner while maintaining a high level of rigor. The challenges of conducting evaluations that keep up with rapid technological change include the trade-off of evaluation rigor and evaluation speed, changes in evaluation criteria and relevant measures due to new information and changes in the industry, changes in the technologies under evaluation themselves, and the likelihood of obsolescence of delayed evaluation findings. Strategies that will be
discussed include early and frequent integration of evaluation with design using empirically-based design and single case study designs, and integration of evaluation within interventions and dissemination activities, with automated randomized controlled trials and quasi-experimental study designs.

Katie Siek, PhD
Dr. Siek will focus on the need for consumer health IT evaluations to account for patients’ workflow and the daily context of the home and community. Although consumer health IT has the potential to benefit patients and other lay users by providing and facilitating the generation of personalized health information, these technologies also have a high abandonment rate. Consequently, we must understand how dimensions of people's daily lives (the technologies they use, their physical and social environments, and their routines) interact with specific consumer health IT interventions to facilitate or hinder adoption, use, and appropriate outcomes. The challenges of accounting for patients’ workflow and daily contexts include gaining long-term access to patient populations and the environments in which consumer health IT solutions are intended for use and an in-depth understanding of patients’ use experiences. To this end, we propose borrowing heavily from Community Based Participatory Research methods and combining them with well-established user centered design and participatory design techniques.

Teresa Zayas-Cabán, PhD
Dr. Zayas-Cabán will focus on the need for consumer health IT evaluations to account for intervention efficacy and safety. Evaluating efficacy of consumer health IT is critical prior to implementation to ensure it works as intended and has the desired effect. The design and implementation of health IT can impact how the system is used and lead to errors, and evaluating the safety of systems patients are expected to utilize “on their own” is critical to avoid causing harm. Challenges to evaluating efficacy and safety of consumer health IT include intervention fidelity, difficulties detecting intervention impact, and distinguishing it from other effects (e.g., patient behavior, concurrently implemented quality improvement programs). When conducting field-based studies there may also be recruitment, enrollment, and follow-up challenges. Strategies to overcome these challenges include a strong recruitment plan with referrals from local organizations (e.g., health sites), a robust design process that contains testing prior to implementation, and leadership buy-in when consumer health IT is being implemented through a clinical or other organization.

Kenneth Goodman, PhD
Dr. Goodman will focus on the need for consumer health IT evaluations to account for ethical considerations. Evaluation itself is an ethical obligation, which must be attended to both before and after implementation. Unfortunately, this ethical obligation to engage in evaluation is often overlooked by the medical informatics community, including when interventions are oriented toward consumers. The challenges of consumer health IT evaluation themselves include ethical issues, including that of consent and privacy. To address these challenges, the consumer health informatics community should borrow approaches to trusted governance, which can have the effect of fostering trust in the communities of patients and other lay users whose health IT use we seek to evaluate. Community engagement then emerges as a strong, useful and symbiotic tool.

Panel Topics
After the introductory presentations, the panel and audience will engage in a discussion of various topics, facilitated by the moderator. Topics relevant to this panel are:

• What are the major barriers to conducting consumer health IT research and evaluation?

• What are common privacy and security concerns that arise during the community-based evaluation and research of consumer facing consumer health IT?

• How do we promote research in community-based health IT interventions, especially those developed by the private sector, not academia, and that do not require FDA approval for commercialization?

• Is a balance possible between (1) streamlining the evaluation process, which may take a long time especially in an academic setting, to keep up with the fast pace of technological change and innovation, and (2) ensuring the evaluation is thorough enough to ensure the safety of patients and their personal health information, and the efficacy of the intervention?
• What are commonalities across different strategies to evaluate consumer health IT?
• How can we engage patients and informal caregivers in evaluating mHealth applications?
• How does evaluation of consumer health IT differ from evaluation of clinical health IT?
• What evaluation techniques for consumer health IT can be borrowed from other domains?
• What challenges exist to developing generalizable knowledge for consumer health IT evaluation?

After the discussion of topics regarding evaluation of consumer health IT, the moderator will lead the panelists in a debate to resolve the following question: Is it possible to identify a unified framework for research and evaluating consumer health IT, or are unique research and evaluation methods needed for different types of consumer health technologies?

Goals of the Panel Discussion
(1) Foster an interdisciplinary dialogue related to consumer health IT evaluation; (2) Provide AMIA symposium attendees with an understanding of multiple consumer health IT evaluation frameworks that they may leverage in their research and practice; (3) Provide AMIA symposium attendees with an understanding of current challenges in consumer health IT evaluation and a call to action regarding future efforts required.

Panel Timeliness
This panel is timely because of the rapid proliferation of consumer health IT. Evaluating the effectiveness of new waves of patient-facing technologies will require merging existing evaluation frameworks with new measures that are specific to novel contexts. Because of its interactive nature, this panel will serve as a forum in which members and panelists can collaboratively advance dialogue related to consumer health IT evaluation. Specifically, audience members will have the opportunity to learn from the panelists and one another about methodological and field-based challenges and innovations that others have encountered and developed. This sharing of experiences will then serve as a foundation for a discussion of future research directions needed to advance the science of consumer health IT evaluation.

All panelists have agreed to take part on this panel.
Patient Portals: Best Practices and New Directions for Development and Investigation

Patricia Dykes, RN, PhD, MA 1, Sarah Collins RN, PhD 1,2, Anuj Dalal MD 1, Cindy Dwyer, RN, BSN 3, S. Ryan Greysen, MD, MHS, MA 4

1 Brigham and Women’s Hospital and Harvard University, Boston, MA
2 Partners HealthCare, Boston, MA
3 Johns Hopkins Hospital, Baltimore, MD
4 University of California San Francisco School of Medicine, San Francisco, CA

Abstract

The meaningful use legislation requirements for patient engagement have led to a greater use of personal health records or patient portals in outpatient settings. However, there are limited examples in the literature that describe strategies and e-health tools to provide patients with access to their health information in hospital or inpatient settings. This interactive panel will explore the findings from a recent study that identified inpatient portal best practices across four “early adopter” healthcare organizations in the United States. Session participants will be involved in refining and identifying new directions for the development and investigation of patient portals.

General Description

Many consumers are using technology to manage health and wellness, and there is a growing recognition of the need for patient engagement in healthcare. The Health Information Technology for Economic and Clinical Health (HITECH) Act meaningful use program (2009) requires that providers engage patients in their healthcare through the use of technology. A key goal of meaningful use is to make consumers full partners in their care by providing e-health tools that increase access to health information, support activation (e.g., active involvement in their treatment plan), and that help consumers to gain control over their health and wellbeing (1, 2). To accomplish this, providers and healthcare organizations have promoted the use of personal health records or patient portals, typically in ambulatory settings (3, 4). There are limited examples in the literature that describe strategies and e-health tools to provide patients with access to their health information in acute care settings. Evaluation of current state of patient portals in acute care settings is needed to inform the development of best practices, to raise awareness of issues and challenges encountered by early adopters, to encourage standardization of features provided to patients, to promote further investigation, and to spur innovation (1).

The LIBRETTO Consortium, funded by the Gordon and Betty Moore Foundation, is exploring best practices for acute care patient portals across four “early adopter” healthcare organizations in the United States. The key goals of the project are to 1) identify key features of an acute care patient portal that are common across sites, 2) recognize common operational and implementation challenges (e.g., workflow, vendors, mobile device security/infection control, etc.), 3) define best practices for acute care patient portal design, configuration, and use (e.g., best practices for patient-provider messaging, delivering educational content, etc.), and 4) propose new directions for investigation and innovation specific to the acute care settings (intensive care and non-intensive care), focusing primarily on personalizing and enhancing the patient/family caregiver experience.

This interactive panel will engage participants in a range of key topics and share lessons learned from the LIBRETTO project. Participants will be encouraged to identify and share additional lessons learned from their institution.

Discussion Topics

For each of the discussion topics below, the panel will present a brief update on LIBRETTO findings and engage the audience in a discussion related to additional experiences and best practices.
What are the common and unique features at each site that serve to engage patients and their care partners while hospitalized in the acute care/ICU setting?

What are key operational and implementation challenges that were encountered? From the patient/caregiver perspective? From the provider perspective?

How does each site plan to enhance the experience of patients and family caregivers using the portal? What is the content that providers want to know about their patients? What information do patients wish to share with providers?

What are the privacy/legal ramifications of providing patients/health care proxies the ability to share aspects of the patient’s plan of care (e.g., schedule) with family members?

How do we deliver educational content most effectively using multimedia modalities?

How do we leverage patients’ social networks and existing social media profiles to set-up their hospital profile to share with providers?

How do we incorporate video conferencing technology to facilitate goals of care discussions with off-site family caregivers and providers?

How do we leverage the full potential of mobile devices? What are the advantages and disadvantages of a hospital-issued device versus bring your own device (BYOD) strategy?

Moderator: Patricia Dykes, RN, PhD, MA is Senior Nurse Scientist and Program Director for Research in the Center for Patient Safety Research and Practice and the Center for Nursing Excellence at Brigham and Women’s Hospital (BWH) and Assistant Professor at Harvard Medical School. Her research interests are in quality and safety of care and adverse event prevention, especially as it relates to hospitalized inpatients. While funded by the Robert Wood Johnson Foundation, Dykes and team developed a fall prevention toolkit that significantly reduced falls in hospitals. She has expanded this research to explore the use of technology to provide the core set of information needed by patients and care team members to engage in safe patient care. Dr. Dykes is a fellow of the American Academy of Nursing and the American College of Medical Informatics. She is the author of two books and over 50 peer-reviewed publications, including the 2013 article in Journal of Gerontological Nursing, Building and testing a patient-centric electronic bedside communication center, which describes the use of a participatory design process to develop and test an inpatient portal prototype to improve access to health information for hospitalized adults and their family caregivers. The prototype was recently enhanced to include additional tools to support patient engagement in their plan of care and is in use by patients and family caregivers on iPads on the medical intensive care and oncology units at BWH.

Panel Members

Sarah Collins RN, PhD is a Clinical Informatician in Clinical Informatics Partners eCare at Partners Healthcare Systems and an Instructor in Medicine at Harvard Medical School and Brigham and Women’s Hospital (BWH) Division of Internal Medicine and Primary Care. Dr. Collins is an experienced critical care nurse. Her research, as well as her applied clinical informatics work, is focused on modeling, developing, and evaluating standards-based, patient-centered collaborative informatics tools to further patient safety and coordinated patient-centered care. Dr. Collins was first author of a 2011 JAMIA publication titled: Policies for Patient Access to Clinical Data via PHRs: Current State and Recommendations. She is leading the MySafeCare research project at BWH. MySafeCare is an application for patients and care partners to electronically submit safety concerns while in the hospital for real-time review via clinical dashboards. This AHRQ funded work includes integration of MySafeCare with the Acute Care Patient Portal at BWH. Her prior patient safety acute and critical research has found significant associations between nursing documentation and patient outcomes of cardiac arrest and mortality development. Dr. Collins’ foundational research aim at increasing patient-centered and collaborative care in the inpatient setting includes development of a conceptual model of Interdisciplinary Information Exchange in the Intensive Care Unit, an Interdisciplinary Handoff Information Coding Framework extending the Continuity of Care Document (CCD) standard for the inpatient setting, and content and functional specifications for a standards-based multidisciplinary rounding tool in acute and critical care.
Anuj Dalal, MD is an Associate Physician and a member of the BWH Hospital Medicine Unit within the Division of General Medicine and Primary Care at Brigham and Women’s Hospital (BWH). He is an Assistant Professor at Harvard Medical School and Fellow of Hospital Medicine. He completed the Program in Clinical Effectiveness at Harvard School of Public Health, and holds a Graduate Degree in Medical Informatics from Oregon Health & Science University. He has expertise in designing, implementing, and evaluating innovative HIT strategies to improve the delivery of care in the inpatient and transitions setting. Specifically, he has worked on initiatives to improve communication of clinically significant test results, optimize care team communication, and facilitate patient engagement with an overall goal of improving patient safety, quality, and healthcare costs. He is co-leading the PROSPECT (Promoting Respect and Ongoing Safety through Patient-centeredness, Engagement, Communication, and Technology) initiative at BWH with Dr. Dykes. The primary goal of this initiative is to engage patients and care partners in the acute care setting implementation of a novel, web-based patient-centered toolkit (PCTK) in the acute care setting. He is leading the effort at implementing a patient-centered microblog that serves as the web-based and mobile messaging platform for the PCTK.

Cindy Dwyer, RN, BSN is a Nurse Clinician III in the Surgical Intensive Care Unit at The Johns Hopkins Hospital. She has worked recently with the Armstrong Institute for Patient Quality and Safety and the Johns Hopkins University Applied Physics Lab in the implementation of the Emerge project. Cindy has combined her over 20 years of critical care bedside nursing with experts in Patient and Family Centered Care to assist in the development and evaluation of a Patient and Family Portal as part of project Emerge. She has completed the Armstrong Institute Patient Safety Certificate Program and is a member of the American Society of Professionals in Patient Safety. Cindy is currently exploring innovative approaches to enhancing the patient and family experience in the intensive care setting.

S. Ryan Greysen, MD, MHS, MA is Assistant Clinical Professor in the UCSF School of Medicine. His research focus is transitions of care for hospitalized older adults and interventions to improve post-discharge continuity of care including novel uses of patient-centered technology such as mobile devices and social media. Dr. Greysen’s mixed-methods evaluation studies have leveraged advanced quantitative and qualitative techniques to inform health policy at the intersection of mobile health, hospital medicine, and geriatrics. His 2014 publication in the Journal of Hospital Medicine shows that hospitalized patients can be more engaged in their care by using tablets to access their patient portal at the bedside and that older or less tech-savvy patients benefit just as much as others if given focused coaching. His ongoing work expands this bedside coaching with portals and integrates mobility sensors to engage older adults/caregivers in goal-setting to avoid complications such as functional decline during hospitalization.

Acknowledgements: We acknowledge The LIBRETTO Consortium, funded by the Gordon and Betty Moore Foundation, for supporting this work. Additionally, we thank Dr. David Vawdrey for participating in our survey of Acute Care Patient Portals Best Practices and his continued work in this space and collaboration in this research.

The Informatics Sculptor & the Clinical Annotator: Effective Annotation Strategies

Panelists

Nancy Gentry, RN, MSN1,6, Elizabeth Hanchrow, RN, MSN1,6, Glenn T. Gobbel, DVM, PhD, MS1,6, Brett R South, MS2,3, and Steven M. Bradley, MD, MPH4,5

Organizer & Moderator

Ruth Reeves, PhD1,6

1Tennessee Valley Healthcare System VA, Nashville, TN; 2 University of Utah, Salt Lake City, UT; 3Salt Lake City VA Medical Center, Salt Lake City, UT; 4Eastern Colorado Health Care System VA, Denver, CO; 5University of Colorado School of Medicine Denver, CO; 6Vanderbilt University, Nashville, TN

Abstract Annotation of free text is an operation requiring human labor, complex cognition and topic-specific knowledge, requiring multiple skills sets in order to be effectively performed. This panel organized around the shared perspective that cross-education of research team members in the disciplines involved is a necessary and desirable function of informatics research. Curating clinical data thru analytic processes including annotation depends on multiple levels of data transform, each requiring expertise from the participating roles involved in the project. This panel discussion includes the following roles: 1) annotator, 2) data quality organizer, 3) NLP developer, 4) clinical expert study designer. Panel members representing one of the roles in integrating annotation data into the research project will discuss tasks and responsibilities of their own role within the process, converging on how their own professional perspective impacts and is impacted by the other roles in the project. The barriers to operationalizing annotation goals will be significantly lowered for attendees of this panel session. Those with an interest in initiating an NLP system for their research or in obtaining quality annotation for other purposes will gain an understanding of ways to best make use of each team member’s particular expertise to obtain quality annotations.

Introduction Annotation of free text is an operation requiring human labor, complex cognition and topic-specific knowledge. In the context of clinical informatics research, it is the process of identifying discrete and often highly variant pieces of textual data (typically within narrative clinical documents) and classifying them for the purposes of establishing normalized equivalence classes for machine-readable processes. More complex annotation tasks may provide signals that aid natural language processing (NLP) systems in performing automated inferencing tasks such as assigning negation, probability scales, chronological ordering or establishing relationships between identified concepts and entities. Traditional View of Annotation in Clinical Research: Medical research projects requiring substantial data extraction from clinical notes often expend substantial resources and time, contracting human reviewers to annotate medical corpora with the relevant clinical concepts and attendant attributes. Historically, such projects recruited physicians. However, this approach has proven expensive, and it is difficult to maintain annotator engagement over the life-time of a project due to competing educational or work-place demands. Alternatively, researchers have attempted acquiring development data by employing non-medically trained annotators aided by clinical subject matter experts, resulting in requiring numerous training cycles and only modest inter-annotator agreement rates. Emergent View of Annotation in Clinical Research: The traditional perspective on annotation labor views it within the pyramid model, with the principal investigator as the author of the study design at the top, the development team as middle managers, and annotators as data entry labor at the bottom. A more innovative approach is a flat-structured interdisciplinary model which organizes around the shared perspective that cross-education of research team members in the disciplines involved (e.g., adverse event documentation practices, NLP, nephrology) is a necessary and desirable function of informatics research.

Discussion Aims The traditional approach to annotation in NLP research is costly, inefficient, and suboptimal. We propose a new approach that fosters interdisciplinary contribution and efficiency. The goal of this panel is to move the audience to see the advantages of annotating within a flat-structured interdisciplinary research setting and to illustrate how to obtain highly reliable and quality annotation data as a function of the overall research project aims. Panelists will comment on and invite discussion on the points of tension involved in annotation procedures in real-life informatics research projects they have been involved in, with a focus on how best to marshal these for producing high quality annotations. The panel will be comprised of four researchers and a moderator who have each had substantial experience with developing or making use of annotation projects in an informatics research operation. Each panel member will address one of the necessary roles in integrating annotation data into the research project: 1) the annotator, 2) the data quality organizer, 3) the NLP developer, and 4) the clinical expert study designer. Each will discuss the tasks and responsibilities of their own role within the process, and converge on how these tasks and his or her own professional perspective impacts and is impacted by the other roles in the project.

252
The presentations will describe how each role trains the other roles, i.e. learning is not one-directional from research PI or clinical expert to annotator.

**Anticipated Audience for Topic of Controversy** Audience participants, either new to or experienced in NLP research, will learn new ways to reduce study risks and costs and associated angst for more productive methods in operationalizing annotation. Investigators with an interest in obtaining quality annotation will gain an understanding of ways to best make use of each team member’s particular expertise. Annotation is often a first step for informatics research projects that include extracting data from unstructured text. In the experience of the panelists and moderator, informatics projects that use annotation require an interdisciplinary approach; leveraging the cumulative knowledge of the annotators and the consumers of the annotation products generates critical contributions to the informatics science of the project. This view veers from the prevailing one of annotation as a necessary burden, to be consumed without need for further cycles of information gain or project wisdom, and it is certainly open to debate; panelists understand both viewpoints and will share their convictions and welcome audience members to do the same for a highly interactive discussion during this panel session.

**Expected Discussion Areas** Topics for discussion include but will not be limited to: Annotator and Team Member Training Can senior annotators train new annotators without having them go through the cross-training experience? What are best practices for annotator training? Are there NLP tools to facilitate the training? Has anyone ever tested the cognitive limits of the complexity of annotation tasks? How well do team members need to understand the science behind each aim? Evaluation Metrics: What evaluation metrics are available for measuring inter-annotator agreement? Are there any “out of the box” tools for calculating rates of agreement? Variant levels of project operational interpenetration: Are there ways to weight annotations according to whether the annotation class represents a clinical variable as opposed to a concept to be filtered? Should such considerations enter into the construction of annotation schemas? Scientific reproducibility: To what use can one put annotated data once the targeted NLP system has been trained and evaluated? Is there a way to use annotation data in conjunction with clinical annotation schemas to facilitate creating common data models? Interdisciplinary Contribution: Should annotators participate in project management and research team meetings? How do the strengths, weaknesses, and opportunities compare between the traditional and the interdisciplinary approach?

**Structure & Discussion Topics** The moderator will initiate the panel discussion, delivering a 10 minute summation of what motivated convening the panel, including a short description of the four key roles. Each of panel presentations (4 panels) of 10-12 minutes will address the tasks associated with their respective roles. Panelists will present workflows, and barriers to task completion as well as lessons learned, inclusive of cross-training experienced or received from other team members. The final 30 minutes will be interactive audience participation.

**Description of Panelists & Presentations**

**Panel 1 Team: Nancy Gentry, RN, MSN** is a Research Nurse Specialist, Vanderbilt University and at the Tennessee Valley Health System, VA. She has had experience in Staff Nursing in the Operating Room and clinical areas at several hospitals, and in Quality Assurance Nursing performing chart reviews of surgical patients at TVHS with the VASQIP program. Elizabeth Hanchrow, RN, MSN is a Research Nurse Specialist, Vanderbilt University and at the Tennessee Valley Health System, VA. She has been a Registered Nurse for 29 years and worked as a staff nurse in a variety of clinical areas including Medical Surgical, Cardiology, Oncology, Pediatrics, Urology, and Women’s Health, and in nursing informatics at Vanderbilt University Medical Center she supported computerized physician order entry and informatics research.

**Panel 1: Nancy Gentry, RN, MSN** together with Elizabeth Hanchrow, RN, MSN will present the role of the nurse annotator, and team function. **Planned discussion summary:** A team presentation of annotation protocol for training and error oversight will be followed by describing the factors contributing to their evolving role as collaborative team members. They will present how they leveraged the task of piloting and iterating annotation guidelines to bring the group to the awareness of the need to operationalize the tension between capturing clinical truth and delivering information to an NLP system. If there is time during the open discussion period they will demonstrate a graphic illustrating the operational procedures for annotation workflow which resulted from this group understanding.

**Panel 2: Brett R South, MS, PhD** is a Senior Scientist in the Department of Biomedical Informatics, University of Utah. Previously he was a Senior NLP Research Engineer for the Nuance Clinical Language Understanding group where he helped lead a group of 75 clinical language analysts tasked with large-scale semantic annotation of clinical corpora to support development of a computer-assisted coding module. His research interests include: clinical NLP, integrating efficiencies with manual human review tasks via improvements in tools, workflow modifications, or distributed review, human cognition, and data analysis. He will discuss the role of the data quality organizer in building a reference standard. **Planned discussion summary:** Dr. South’s presentation will be leverage his experience as data quality manager for many annotation projects including i2b2 2010/2011, de-identification,
disease surveillance, extracting information representing variables for carotid stenosis, readmission risk factors including social determinants of health (SDOH), and activities of daily living (ADLs)/instrumental activities of daily living (IADLs), functional status indicators, and other data normalization tasks. His presentation will be in the context of the data quality organizer focusing on the stages most common to NLP projects that are necessary to annotate clinical texts and generate reference standards that can be used for NLP system development and statistical performance evaluation. These common stages require independence in human review and require considerable effort and are often cognitively intensive. These stages include: 1) developing and pilot testing annotation guidelines and schemata; 2) training annotators; 3) performing the annotation task; 4) adjudicating disagreements and/or building consensus sets to create a final reference standard; and 5) estimating task reliability and validity. These tasks may also require clinical expertise at the sub-specialty level to reduce ambiguity in annotation guidelines and schemata, and to adjudicate disagreements. This presentation will discuss each of these stages as they relate to building reference standards that are of high enough quality to be used for NLP system development.

Panel 3: Glenn T. Gobbel, DVM, PhD, MS is a Research Assistant Professor in Health Services Research at the Tennessee Valley Health System and within the Department of Biomedical Informatics at Vanderbilt University. His work has focused on the development of near-real time NLP tools for extraction of medical information from free text and machine-learning based tools that rely on online learning for assisted annotation. He is currently a co-investigator on six nationally-funded projects focusing on the development of NLP systems for clinical use. His presentation will focus on the goals of annotation from the perspective of an NLP developer. Planned discussion summary: Dr. Gobbel’s presentation will be informed by his own experience developing NLP systems for extracting information with respect to cirrhosis, acute kidney injury, congestive heart failure, and patients undergoing cardiac stress tests. A key goal of annotation for an NLP developer is generally to create the data that can be used to produce, train, and test an NLP system to effectively extract medical concepts of interest and associated data. This presentation will describe some of the challenges associated with and approaches to generating such a system and creating the annotation schema and guidelines to accomplish this.

Panel 4: Steve Bradley, MD, MPH is Assistant Professor of Medicine in the Division of Cardiology at the University of Colorado, School of Medicine and a VA Health Services Research & Development Career Development Award (CDA) recipient. His research is focused on understanding the determinants of high-quality and high-value care delivery. He has conducted several national studies evaluating variation in the use and appropriateness of coronary angiography and PCI in addition to studies on the processes and outcomes of cardiovascular care delivery. In addition, he is the PI of a project grant funded by the VA to develop and validate an NLP application to abstract structured data from text reports of stress tests performed in the VA. This tool intends to address the absence of interpretable data on stress test results that limits opportunities to measure and support quality of risk factor modification and the high-quality use of procedural care for patients with ischemic heart disease.

He will discuss the role of the clinical expert in charge of the study design of the informatics project which consumes the products of NLP output. Planned discussion summary: As a cardiologist and health services researcher, Dr. Bradley seeks to understand the determinants of high-quality and high-value cardiovascular care. Currently, cardiovascular care lacks structured data on the indications and results of cardiovascular stress tests. This lack of data severely limits the ability to assess the quality of care for patients with ischemic heart disease. Accordingly, Dr. Bradley’s VA funded project sought to develop and validate an NLP application to abstract structured data from text reports of stress tests performed in the VA. Prior to working on this project, Dr. Bradley had no experience in the development of a NLP tool. In this panel discussion, he will share his experience in the transition from novice to somewhat experienced NLP tool developer from the perspective of a clinical champion who seeks to improve the quality of health care.

Ruth Reeves, PhD is a Health Services Research Scientist at the Tennessee Valley Health System, US Department of Veterans Affairs and an Assistant Professor in the Department of Biomedical Informatics at Vanderbilt University. She is currently principal investigator on a nationally funded merit award which deploys NLP methodology to temporal reasoning within the electronic health records of veterans suffering Post Traumatic Stress Disorder and is a co-investigator on six nationally-funded projects focusing on the development of NLP systems for clinical use. She will serve as the moderator of the panel. She will initiate the panel discussion, facilitate discussion and introduce each panelist with a brief statement of the role he or she represents within the annotation workflow. Planned discussion summary: Every research team member represents a cost to the project; no cost need be judged more burdensome than another if all knowledge and expertise represented within the research team can be optimized through continual and iterative cross-education among team members. Annotators bring the data to life and expose the complexities of both the project goals and the realities the study is meant to uncover. Developing and maintaining this touchstone of evidence is the lifeblood of successful clinical research.

Participation Statement: All proposed panelists have agreed to participate in the panel.
Interactive Panel: Open Architecture for Pathways/Care Coordination

Robert A. Greenes, M.D., Ph. D.\textsuperscript{1,2}, Steven J. Demuth, B.A.\textsuperscript{3}, Matthew M. Burton, M.D.\textsuperscript{3}, Davide Sottara, Ph. D.\textsuperscript{1,3,4}, Keith M. Toussaint, B.S.E.E.\textsuperscript{4}

\textsuperscript{1}Arizona State University Department of Biomedical Informatics, Scottsdale, AZ; \textsuperscript{2}Mayo Clinic, Scottsdale, AZ; \textsuperscript{3}Mayo Clinic, Rochester, MN; \textsuperscript{4}Healthcare Services Platform Consortium, Scottsdale, AZ

Abstract

Current health IT has evolved over many decades as a patchwork of proprietary legacy systems for managing electronic health records (EHRs), providing decision support, facilitating workflow, finances, and quality management, among other functionality. The closed, proprietary nature of the architecture and underlying technologies in these systems has resulted in silos of data, fragmentation of the patient records, difficulty coordinating care, and difficulty evolving to address the needs of the future. In order to better support the needs of clinical pathway development and care coordination, leading health care organizations should work together with leading open technology providers to create open architecture, open interface and open source community cloud computing environment. The presence of such an environment would enable a new generation of health information technology innovation resulting in information technology tools that would be better suited to meet the needs of a health care future where delivering best practice care to patients in every setting is the norm.

Intended Audience

The intended audience includes those who have an interest in applying modern, web-based architectural principles to health care information technology. More specifically, those who have a strong interest (pro or con) in introducing open architecture, open interface, open source and cloud-based approaches in health IT. The aim of the discussion will be to propose a broad industry effort to bring the aforementioned principles into the mainstream of health information technology development.

Introduction

This panel discusses opportunities, challenges, and possible approaches to creation of a new information technology ecosystem for health and health care. Much has been written about the forces driving the need for more connected, integrated, coordinated health and health care, the payment system reforms seeking to move health care in this direction, and the technology requirements for interoperable, standards-based architectures needed to bring it about.

Current health IT has evolved over many decades, particularly in the US, as a patchwork of proprietary legacy systems for managing electronic health records (EHRs), providing decision support, facilitating workflow, finances, and quality management, among other functionality. But these have been focused on particular hospitals, practices, or enterprises, resulting in silos of data, fragmentation of the patient records, difficulty coordinating care, and difficulty evolving to address the needs of the future. These needs include better summarization and visualization of data especially for complex patients, management of the patient’s care across multiple venues from home to office to hospital, more direct self-management of health and of care by patients, more comprehensive workflow management and decision support both for patients and providers, and the use of the ever-expanding volume of data to provide better analytic support for care decisions, quality management, research, and public health, and for other purposes, all in a manner that provides security and protects patient privacy.

Aim of the Discussion

The panelists represent some activities that are being taken to help bring about a new framework for interoperable apps and standards-based services to meet new health IT challenges. By briefly introducing them and describing the vision of how these relate to one another, we seek to stimulate interaction with the audience about the opportunities, obstacles, alternative approaches, and ways of proceeding that can lead to realization of the vision of a new vibrant ecosystem.
Specific Contributions of Each Speaker

Robert A. Greenes: The Arizona State University (ASU) Department of Biomedical Informatics is seeking to promote the further development of an evolving standards-based platform on which to develop apps and services that address needs of collaborating entities to meet evolving health care tasks not met by their EHR systems alone. The goal is to provide a sandbox and testbed development environment for evolving solutions that are interoperable and interface with underlying EHRs and other data sources and obtain and coordinate various services with those systems. Figure 1 is an example of a software architecture based on this approach. It provides opportunities to health care organizations to obtain add-on functionality that has been heretofore locked into proprietary vendor offerings, allows competition at the app level, and provides functions that bridge or extend those existing systems through evolving middleware services. An app design and deployment tool known as AppWorks is used to facilitate composition of multi-function apps using knowledge-based filters and event triggers.

Matthew M. Burton: In parallel and working with ASU colleagues, Mayo Clinic has developed software to support the optimal use of clinical pathways in the care of its surgical patients. The EASE (Enhanced Analytics for Achieving Surgical Excellence) project has built a care pathway management and monitoring application and framework that employs user interfaces that embrace clinician mental models, embodies the design principles of separation of concerns, uses open architectural principles (see Figure 2), open interfaces and open source components.

Jonathan R. Nebeker: The Veterans Administration’s Vista Evolution Program has an architecture and framework that supports interoperability, based on a three-tiered architecture that has similarities to those described above. Driving needs include care coordination: patient-centric, team-based care with capabilities for quality improvement; new user experience with multifaceted support for understanding and decisions that speed use of the EHR and improve quality of clinical reasoning; and capability for technical, semantic and process interoperability with external systems with which VA health care must communicate.

Oscar Diaz: The Healthcare Services Platform Consortium (HSPC) is a not-for-profit community of healthcare providers, software vendors, educational institutions and individual contributors who facilitate clinical application interoperability and data sharing by defining open, standards based specifications for enterprise clinical services and clinical applications. HSPC ultimately hopes to achieve interoperability and sharing of clinic assets across the entire health care domain.

Figure 1. An Interoperable-App-Enabling Architecture for Health Care, showing its 3-tiered architecture with apps, middleware services, and data sources at the 3 tiers.

Figure 2. EASE Solution Architecture
Keith Toussaint (panel organizer and moderator): Mayo Clinic and other health care organizations are seeking to adapt their business models and health care services to the transformation of the health care system and to continue to do what they do best while finding new ways to thrive and grow. The need for development of new health IT approaches is essential, and Mayo Clinic has been active in pursuing approaches to this challenge.

**Expected Discussion**

*Fostering a New Ecosystem for Health IT: Three Capabilities Needed*

A new ecosystem is in its very early stages for health IT, as a growing number of health care organizations (HCOs) are finding the need for it, as well as investing in it with their own internal funds and venture initiatives. The Federal government and many payers, health care researchers, and health professionals are trying to foster it. For such a vision to come about, three inter-related capabilities are proposed to be considered by the audience:

1. A specification for a standards-based architecture/framework that will foster interoperable apps and services – that is agreed upon and supported by both health care organizations, payers, vendors, and other stakeholders.

2. Methods for reliably operationally deploying apps and services in a robust, secure, mode – that ensures their ability to interoperate with and utilize existing EHR systems and other data sources, and to extend them in a smooth and highly reliable way. A leading approach to doing this is through a cloud-based Platform-as-a-Service ("PaaS") model.

3. Communally supported collaborative development resources – that enable (a) evolution of the capabilities of the standards-based architecture; (b) development and refinement of apps and services that use it; and (c) a migration path to reliable operational deployment and/or commercialization for apps and services that are developed and found to be suitable.

**Why Timely and Controversial**

Based on the initial success of the efforts by the presenters and interaction with colleagues in other institutions, we believe that there is a broad need for these capabilities across the health care sector. We therefore encourage an industry-wide effort to establish an open architecture, open interface, open source cloud-based initiative to facilitate interoperable apps for the advanced functionality which will enable further development of optimal care pathway and care coordination tools.

Nonetheless, such a framework does not currently exist yet in health care, and many factors such as legacy infrastructure, regulations, payment reform, and Meaningful Use requirements can greatly alter the speed and priority of adoption of interoperability and the forms it will take. There are alternative ways to achieve many of the goals, and heavy financial investment by both vendors and health care organizations and payers in them. There are also a number of organizational entities that are seeking to foster various aspects of interoperability. The feedback we are seeking should address the challenges that need to be faced and strategies that would be best to pursue.

**Agreement of Panelists**

All participants have agreed to take part on the panel.
(Authoring) Rules, (Distributed Query) Tools, and Drools: The challenging new world of high throughput phenotyping.

Jennifer A. Pacheco1; Abel Kho MD, MS1; Jyotishman Pathak, PhD2; Joshua C. Denny, MD, MS3; Shawn Murphy, MD4
1 Feinberg School of Medicine, Northwestern University, Chicago, IL, USA; 2Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA; 3Department of Biomedical Informatics, Vanderbilt University, Nashville, TN, USA; 4Center for Research IS and Computing, Partners Healthcare, Boston, MA

Abstract
Deriving phenotypes from electronic health records (EHRs) is in progress within several national networks, including the electronic Medical Records and Genomics (eMERGE) network1,2, the Pharmacogenomics Research Network (PGRN)3, the SHARPn (Strategic Health IT Advanced Research Projects)4, and PCORnet5, to name only a few, and those phenotype definitions are also now being shared across those networks. Two main obstacles make it more difficult to share those EHR derived phenotypes across sites, and especially networks: 1) the absence of clear, unambiguous phenotype algorithm definitions represented in a standardized, if not executable, format that can easily be shared, and 2) the use of different standard data representations, and varying data models. This panel will discuss the varying array of methodologies, informatics tools, and data standards and data models for sharing and executing EHR derived phenotypes. The panel will also discuss efforts to harmonize data models and phenotyping informatics tools across the multiple parallel national efforts mentioned here.

A general description of the panel and issues that will be examined
Networks such as the Electronic Medical Records and Genomics (eMERGE) network have pioneered use of phenotype algorithms for use in EMRs, though their use in clinical studies predates this. Typically, phenotype algorithms have employed Boolean or machine learning methods across multiple classes of information (billing codes, medication data, natural language processing, and laboratory and test data) to accurately define cases and controls from EHR data. To date, eMERGE has investigated ~30 validated phenotypes via genome-wide association studies. In addition, eMERGE sites with other networks such as PCORnet have explored use of computable phenotype algorithms using tools such as KNIME (Konstanz Information Miner)6,7 and Drools to represent phenotype algorithms using computable languages with some success. Algorithms in eMERGE, PGRN, NIH collaborator, and PCORnet are being shared on PheKB.org.

The approach taken in i2b2 to date has been to use a statistical assessment; fitting a selection of possibly relevant attributes that describe a phenotype to a regression-type algorithm. This has been shown to accommodate to a wide variety of attributes that may be present or derived from the EHR, and is reasonably consistent form one site to another.8-9

New software tools are also currently being developed to author standardized phenotype algorithm representations that can be converted into executable format, such as one being developed by the Phenotype Execution Modeling Architecture (PhEMA) project10, which will use another common data model, the Quality Data Model (QDM)11,12. In addition, existing sharing of phenotype algorithms is usually in simple non-standardized textual and graphical format, let alone executable format, except in a few cases that we know of within the eMERGE network where executable workflows created using the open-source KNIME analytics platform are being used and shared by some eMERGE sites.

The panel will introduce and discuss with audience members involved, and/or interested, in sharing EHR-derived phenotypes, the following:

- Is a standard format needed for sharing phenotype algorithm definitions? If so, what should that look like? If not, why not? Are there several different formats we should be using depending on different use cases, and if so, what are those use cases?
- Should phenotype algorithms be shared ideally in executable format? If so, what should that format look like, & should it depend on a common data model? Are there different types of executable formats that
should be shared (i.e., KNIME vs. JBoss Drools), that would depend on the use case for those phenotypes? What are those use cases and thus what should those formats look like?

- Standard languages (and corresponding data representations) have been created for quality measures, such as the Quality Data Model. Are these sufficient for research uses, and why or why not? Or are common data models necessary for some use cases but not for others, & if so, which ones? How can we harmonize data (and data models) to enable more efficient and accurate sharing of phenotype algorithms? In addition, what data standards should be used?

- What are the most promising approaches to obtaining an accurate and portable phenotype? Rule based approaches and statistical approaches have been used to refine the phenotypes of the EHR which have afforded increases in sensitivity and positive predictive values. However there are tradeoffs of complexity, reproducibility, and portability which need to be made. Different approaches have optimized various parts of the desired outcome of obtaining an accurate phenotype.

Panelist’s perspectives

Jennifer A. Pacheco – Moderator

Mrs. Pacheco is a biomedical informaticist and the informatics lead for NUgene, the EHR-linked biobank at Northwestern University, and an active member of the phenotype working group of eMERGE, as well as PhEMA. She is also a previous member of PGRN. In these roles Mrs. Pacheco has co-led the development of over a dozen phenotype algorithms & led the validation and/or execution of over 50 EHR-derived phenotypes.

Abel Kho

Dr. Kho is an Assistant Professor of Medicine and Preventive Medicine at Northwestern University and a member of the phenotype working group of eMERGE and Co-Chair of the PCORnet Data Standards, Security and Network Infrastructure Task Force. He led Northwestern’s GWAS of genomic variants associated with Type 2 Diabetes (T2D) and more recently diverticulosis and diverticulitis. Dr. Kho will compare phenotyping experiences in eMERGE and PCORnet.

Jyotishman Pathak

Dr. Pathak is an Associate Professor of Biomedical Informatics at the Mayo Clinic College of Medicine. His research focuses on developing methodology and applications for standardized and computable phenotyping algorithms. Dr. Pathak will describe recent progress from the SHARPn collaboration developing open-source solutions for high-throughput and scalable phenotyping using Hadoop-based big data technologies, and highlight ongoing work in creating a robust platform for phenotyping algorithm authoring and dissemination. Dr. Pathak has also led the development of phenotype data harmonization platform within eMERGE and PGRN.

Joshua Denny

Dr. Denny is an Associate Professor in the Department of Biomedical Informatics at Vanderbilt University, and was the SPC chair of the 2014 Summit on TBI. Vanderbilt uses an opt-out model biobank associated with a deidentified Synthetic Derivative of the EHR. Vanderbilt’s has used BioVU for more than 100 studies, including investigation of >40 diseases and >30 pharmacogenetic phenotypes led by Dr. Denny. Many of these algorithms have been originated in or have been shared with the eMERGE or Pharmacogenomics in Very Large Populations (PGPop) networks. For example, one study selected individuals without cardiac disease and studied influences on cardiovascular traits, finding variants influence slower intracardiac electrical conduction. Phenome-wide association study (PheWAS) demonstrated some of these variants confer risk for atrial fibrillation, and a survival analysis of this original heart healthy population demonstrated similar risk of development of atrial fibrillation during the up to 20-year follow-up in the EHR. He also developed algorithms and software to perform PheWAS, scanning the EHR phenotype for genetic associations with many diseases not anticipated in the initial GWAS, and use of this tool to explore pleiotropy in current GWA studies. Dr. Denny has also led development of PheKB.org to share phenotype algorithms and phewascatalog.org to share PheWAS results.

Shawn Murphy

Will introduce i2b2 and its federated query platform SHRINE (Shared Health Research Information NEtwork) as a research informatics platform and their position statement including approaches it has taken to solve problems in phenotyping using the EHR. Dr. Murphy will continue with discussion of i2b2 design philosophy as it regards data
modeling, ontologies, standards and terminology systems and how these can be woven together to provide the basis for dealing with the many aspect of phenotyping in our community. Will describe the optimal i2b2 ecosystem (tools, application development frameworks it supports, products and use-cases) and end with the future development roadmap for providing phenotyping tools.

**Plan for interaction between panelists and the audience**

The moderator will encourage the audience to interact with the panelists through questions such as those above and by encouraging discussion and comments on current methods for sharing and executing phenotypes within and across the aforementioned national initiatives.

All participants have agreed to take part on the panel.

**References**

3. Pharmacogenomics Research Network, pgm.org
Abstract

Many healthcare institutions face a second crisis in electronic health record system (EHR) implementation: migrating from one mature commercial or home-grown EHR to another. A considerable portion of the healthcare market is now converting to a second or third EHR system. AMIA members, ostensibly, have examined in great detail the challenges of initial EHR selection, implementation, adoption, and the shift away from paper records. Research is missing or sparse to guide informaticists and information technology specialists on the challenges and support for subsequent implementations.

This panel seeks to accomplish the following:

- Recognize that one important implementation issue is migrating from one mature EHR to another;
- Explore the advantages of such shifts;
- Discuss extant evidence-based literature on system migration, or “re-implementation”;
- Identify the conversion risks and costs;
- Distinguish often unforeseen consequences;
- Guide others in this common endeavor.

Panelists will explore what is known via anecdotal sources, listserv discussions, personal experience, and the relatively few published studies related to this topic. We shall solicit information from fellow AMIA members and present new information. Panelists will declare their positions on these topics, followed by questions proffered to each other in an attempt to stimulate audience participation in the open discussion period.

General Description

Description of intended audience

The intended audience consists of the following people: clinicians in institutions considering or undergoing EHR migrations; frontline operations informatics professionals, including Chief Medical Informatics Officers, as well as information technology leaders such as Chief Information Officers and Chief Operating Officers, who frequently manage implementations and transformations in healthcare institutions, trainers, HR professionals who must adjust workloads during the training and ramp up process, Chief Financial Officers who must manage the costs of these shifts, patient relations personnel who are often called upon to smooth transitions and not alarm patients as clinicians learn to use the new systems; as well as informatics researchers who examine clinical information system and
implementation issues. These clinical leaders and researchers need the input of users of systems who are impacted by such a change, as usability is a critical factor that can predict the success or failure of such a transformation.

**Issues that the panel will address**
- Presentation of the new paradigm towards system migration: Why break what’s not broken? Or isn’t it?
- What is driving this new paradigm: consolidation, mergers, acquisitions, affiliations, and new payment modalities?
- What does the community hospital need to do?
- What does the academic medical center need to do?
- What do Critical Access Hospitals and other small, rural hospitals need to do?
- What are the human, sociological, and financial costs of these transitions?
- What are the risks?
- Can smaller institutions keep up with the financial strain of conversions?
- What role do larger institutions have in terms of population health, accountable care, and value based payments?

**Aims of the discussion**
The goals of this interactive panel discussion are to:
- Introduce members of AMIA and the informatics community to this emerging—but increasingly common—phenomenon;
- Propose and discuss expected challenges when changing EHR products;
- Develop the appropriate research questions to enable objective investigation of the issues

**Specific contribution of each speaker**
The panelists will each speak for approximately 10 minutes. The perspective of the first speaker is to introduce the paradigm shift, and present the point of view of the community hospital. The second speaker will address the perspective of the large academic or university center. The third speaker will discuss the position of Critical Access Hospitals and other small, rural hospitals and will assess the risks for those clinicians, clinics, and hospitals that may not be able to participate in such a transformation. The fourth speaker will review the human, sociological, and financial impacts of EHR shifts. All panelists will then answer questions addressed to them from the other panelists, and from the audience.

**Expected discussion**
Each speaker will pose provocative questions to at least one of the other speakers on the panel, and each speaker will be given 5 minutes to answer in the format of a friendly debate. The audience will have a chance to participate in the remaining 30 minutes of the program.

**Explanation of why the topic is timely and controversial**
Interoperability, Meaningful Use, optimization of clinical decision support, and payment system reform have dominated recent discussions regarding EHRs. Part of AMIA’s mission is to keep informaticists and related scientists informed about, and prepared to address, emerging trends in healthcare information systems. Concern about the consolidation of the vendor marketplace will add additional urgency to these phenomena. We already observe examples of problems when healthcare entities merge, but their EHR systems do not. This panel will explore all aspects of this new problem.
Panel Members

Richard Schreiber, MD

Richard Schreiber, MD, FACP, is Chief Medical Informatics Officer at Holy Spirit Hospital (HSH)—a Geisinger Affiliate—in Camp Hill, PA, who is board certified in Clinical Informatics, and is also a general internal medicine hospitalist.

John D. McGreevey III, MD, FACP

Dr. John D. McGreevey III is a general internal medicine hospitalist attending at Penn Medicine, an Assistant Professor of Clinical Medicine at the Perelman School of Medicine at the University of Pennsylvania, and a general internal medicine hospitalist.

Catherine K. Craven, PhD, MLS, MA

Catherine K. Craven, PhD, MLS, MA, Immediate Past Chair, Evaluation WG, graduated from the doctoral program in Health (clinical) Informatics in December 2014, from University of Missouri, Columbia, Mo. Her research focuses on rural and critical access hospitals.

Ross Koppel, PhD, FACMI

Dr. Koppel studies, and is an advocate for, improving healthcare IT—the implementation process, workflow, human-computer interactions, vendor-provider relations, legal and ethical aspects of CDS and HIT, and of HIT’s usability. His articles in JAMA, JAMIA, Annals of Internal Medicine, NEJM, Health Affairs, J of Patient Safety, etc. are often considered seminal works because his original training as a sociologist of work, the professions and technology allows him to combine ethnographic research, extensive statistical analysis, surveys, observations, interviews, organizational and financial analyses, and usability studies. Dr. Koppel is a Fellow of the American College of Medical Informatics.

Participation Statement

I, Richard Schreiber, hereby confirm that all panelists listed in this proposal have agreed to participate in this panel. Panelists are aware that there are no travel funds available. Panelists are also aware that the Working Groups are unable to reimburse their registration costs.

Patient privacy and “de-identified” health records in the genomic era

Jessica D. Tenenbaum, PhD1, Greg Biggers2, Leslie E. Wolf3, Bradley Malin, PhD4, Lucila Ohno-Machado, PhD5

1Duke University, Durham, NC 2Genomera, Palo Alto, CA 3Georgia State University College of Law, Atlanta, GA 4Vanderbilt University, Nashville, TN 5UC San Diego, La Jolla, CA

Abstract

Current policy allows researchers to use de-identified data from electronic health records for research purposes. Data is considered de-identified if eighteen identifying fields, including name, address, phone number, social security number, etc. are stripped off of the derived dataset. However, in the era of precision medicine, detailed genomic data will increasingly be stored along with patients’ clinical data. Genomic data, particularly whole genome/exome sequencing is, by definition, identifying. The availability of genomic data together with clinical information represents a rich resource for science, but also introduces ethical challenges around patient privacy. How can we manage the research demand for data while respecting patients' concerns, interests, and rights? On what "truths" does everyone agree today, and what are the potential sticking points down the road? What can we, as informatics researchers, do to help? These are just some of the timely and compelling issues that will be addressed by this diverse panel, featuring technical, ethical/legal, community, and patient’s rights perspectives.

Introduction

Current policy for secondary use of health records allows researchers to use electronic health record (EHR) data for research, so long as the records are “de-identified” by stripping out 18 identifying fields, including name, address, phone number, social security number, etc. However, in the era of precision medicine, detailed genomic data will increasingly be stored along with people’s clinical data. The availability of genomic data together with clinical information represents a rich resource for science, but also introduces ethical challenges around patient privacy [1].

There are some who argue that the risks of re-identification have been overstated, causing unnecessary obstacles toward scientific progress. Others have demonstrated the relative ease with which they were able to re-identify an individual based on publicly available genomic and ancestral information. Up until now, these issues have been largely academic, but as more genomic data is incorporated into health records, and as we move toward a future in which individuals have their genomes sequences as part of routine care, the issue becomes more germane. The advantages to using such data for research will be significant, particularly in light of the large sample size required for statistical significance for any but the most straightforward genotype/phenotype relationship. However, if we continue on the current path, and with the current interpretation of the law, patients who have never consented to research will have their unique genomes shared on servers across the world without ever being aware.

It should be noted that these issues have implications not only for secondary use of EHR data, but for medical research as well. If DNA is designated as identified data, then the possibility of studying it as part of a limited or de-identified dataset is eliminated. Similarly, NIH Genome Sequence Data Sharing policy currently states that DNA is de-identified, but it acknowledges there is a potential for identification, such that it requires consent for every record submitted to dbGaP moving forward.

Researchers, together with other key stakeholders including patients and patient advocates, must identify and discuss these issues sooner than later, so that all parties can understand the issues and perspectives at hand, and come to agreement as to how to proceed moving forward.

Timeliness of Topic

This topic is particularly timely in light of the White House’s recent announcement around the Precision Medicine Initiative, aimed at uncovering “individual differences in people’s genes, environments, and lifestyles” to enable more targeted and effective treatments. [2]
Intended Audience
The target audience for this panel is quite broad, ranging from investigators whose research uses electronic health record data, to those who focus on genetic and genomic data for whom this new landscape will be particularly alluring, to anyone who has, or may someday have, genetic data associated with his or her medical records.

Speaker Contributions
This panel will discuss the issues raised above from several different perspectives: ethical/legal (Wolf), technical (Ohno-Machado, Malin), community (Malin, Biggers) and patient perspectives (Biggers).

Jessica D. Tenenbaum- Duke University- Moderator
Dr. Tenenbaum will frame the topics to be addressed and introduce the panel speakers, and will moderate the presentations and the discussion to follow.

Leslie E. Wolf- Georgia State University School of Law
The coming existence of millions of interoperable electronic health records with genomic sequence or SNP data will present researchers with tremendous opportunities. But using those records for research without consent (as permitted under existing laws) risks undermining public support for research. How can we manage the research demand for data while respecting patients’ concerns, interests, and rights?

Lucila Ohno-Machado- UC San Diego
Dr. Ohno-Machado will discuss patient preference elicitation for sharing clinical data and biospecimens. She will provide preliminary results of a study being conducted at two academic medical center clinics in which patients decide what to share and the CTSA informatics team delivers data to investigators as appropriate. She will also discuss how genomic data could be accessed for research without compromise of patient privacy, and the security environment in which the data should reside.

Brad Malin- Vanderbilt University
Dr. Malin will discuss the role of community consultation and advisory groups as it pertains to opt-in and opt-out. He will also discuss how secondary use of genomic and clinical data post-consent (regardless of the opt-* strategy) relate to the notions of de-identification and the extent to which this is a worthwhile protection given current threats to such protections. His comments will be centered around his experience with the establishment and management of a large biorepository at Vanderbilt University and other medical centers involved in the NIH-sponsored Electronic Medical Records and Genomics (eMERGE) Network.

Greg Biggers- Genomera, Genetic Alliance
How do we navigate the tensions between vigorous biocivics and the emerging reality that de-identification of precision medicine data is a myth? How do people act when privacy and health seem to be at odds with one another? And what happens when subjects become researchers? Biggers will discuss lessons in privacy, control, engagement, and trust learned from grassroots projects including Genomera (participant-driven health studies) and Genetic Alliance's PEER (Platform for Engaging Everyone Responsibly), as well as his own experience as a patient with a sequenced genome.

Panel Discussion Aims and Expectations
We expect a lively discussion to follow the presenters’ prepared comments. The topic is not highly technical, but is one that could, and most likely will, someday affect almost every conference attendee. Discussion is likely to address patients’ rights to privacy, whether we enter into an implicit social contract when we seek medical attention, issues of probability and numeracy, legal protections (both existing and desired), appropriate consequences of data abuse, and more.

Conclusion
Data privacy in the genomic era is a complex but addressable issue. As it stands, only a small fraction of the population currently have genomic data associated with their medical records, but the numbers are increasing every day. The time to have these conversations is now.
Participants’ Agreement to Attend

All speakers have indicated the intention to participate in this panel.

Abstract

Biomedical research and practice have never been more interdisciplinary than they are today, and yet interdisciplinary training in biomedicine remains the exception and not the rule. AMIA has a number of initiatives, from working groups to the annual Summit on Translational Bioinformatics, which emphasize the importance of the “bio” end of the biomedical informatics spectrum. However, there is significant opportunity for collaboration with other organizations with complementary expertise. AMIA has significant capabilities in informatics to support precision medicine. The American College of Medical Genetics and Genomics has significant expertise in medical genetics and genomics to improve human health. This panel brings together thought leaders from these two organizations to discuss the challenges in training tomorrow’s workforce for precision medicine, and the possibilities for interprofessional educational opportunities.

Background

Biomedical research and practice have never been more interdisciplinary than they are today. This fact is underscored by a number of trends in recent years, not the least of which has been the Health Information Technology for Economic and Clinical Health (HITECH) Act and its requirements for the adoption and meaningful use of electronic health records. More recently, in January 2015, President Obama announced a $215M Precision Medicine Initiative aimed at the treatment and prevention of disease that take into account individual variability in genes, environment, and lifestyle. [1] Despite these initiatives and the significant need for interdisciplinary education, such training in biomedicine remains the exception and not the rule.

AMIA has had a long standing interest in, and commitment to, the importance of biology in the broader field of biomedical informatics. The theme of AMIA’s annual symposium in 2002, titled “Bio*Medical Informatics: One Discipline”, could be seen as a harbinger of themes from the decade plus since, including genomic, personalized, and precision medicine. Similarly, the establishment of the annual Summit on Translational Bioinformatics in 2008 served as a professional gathering for biomedical informaticists whose focus lies at the molecular end of the biomedical spectrum. Beneficial though that venue has been to this community, communication and cross pollination with other organizations focused in this area has been suboptimal. This proposal, submitted in collaboration with the American College of Medical Genetics and Genomics (ACMG) aims to enhance communication between our respective organizations and to spark ongoing collaboration through exploration of this topic of mutual importance, potentially leading to opportunities in interprofessional educational opportunities.

Introduction

The establishment of Clinical Informatics as a Board Certified medical specialty in 2011 was an important step toward training an informatics-enabled workforce of tomorrow, and 2013 and 2014 saw more than 700 physicians board certified in clinical informatics. AMIA played a key role in the establishment of this sub-specialty, through an 18 month, RWJF-funded process to define the core content of the subspecialty of clinical informatics and the training requirements for proposed clinical informatics fellowships. For professionals not eligible for certification in a medical sub-specialty, e.g. non-physicians, the Advanced Interprofessional Informatics Certification (AIIC), arose out of AMIA's Academic Forum in 2011. Directed by Don Detmer, MD, past president and CEO of AMIA, the AIIC aims to develop a qualified and sustainable informatics-trained workforce not only as a medical subspecialty, but also as a viable career path for non-clinicians in complementary fields, e.g. informaticians, computer scientists, dentists, public health professionals, etc.

The American College of Genetics and Genomics (ACMG) provides education and resources for professionals in the field of medical genetics. It also serves as the voice for these professionals on important topics of interest to the larger biomedical community. A prominent recent example is the ACMG’s recommendations regarding return of results in
clinical exome and genome sequencing. [2] The ACMG leads the development of professional practice guidelines for both clinicians and laboratorians, creates educational content (e.g. ACT sheets for newborn screening and other disorders) to aid non-geneticists in managing patients with rare genetic conditions. ACMG is also involved in the NHGRI funded Clinical Genome (ClinGen) project which will be developing online resources and informatics tools to support the use of genomic variant information in clinical care. [3] At present accredited genetic training programs do not have defined competencies, formal training in, or exposure to informatics. The leadership of the ACMG recognizes informatics as essential to the realization of Precision Medicine and is looking to partner with content experts such as AMIA to provide content for their trainees.

Key areas for enhanced training opportunities include (but are not limited to): genetics, genomics, high throughput technologies, biostatistics, molecular systems biology, data standards and analytics, clinical informatics, clinical decision support, evidence-based patient care, human factors engineering, health IT systems and applications, and team science.

In this panel, AMIA thought leaders in the areas of precision medicine have come together with colleagues from the ACMG to discuss the issues and opportunities that arise as we begin to lay out a strategy for training the workforce that will be required to execute on the vision of Precision Medicine, and how our organizations can work together to achieve these educational goals.

Intended Audience
This topic will be of interest to a broad AMIA audience including informatics professionals who are currently practicing or interested in pursuing training in genetics and genomics, as well as educators who aim to expand their department’s offerings, whether within their home institutions, or virtually online.

Topic Timeliness and Controversy
The federal government has announced its intention to devote $215 million in funding to the Precision Medicine Initiative in the President’s 2016 budget. More importantly, as discoveries are made through this initiative and translated into clinical practice, the distribution of the $3 trillion spent each year in the US will inevitably shift. Those trained to leverage and execute on these new discoveries will be at a significant competitive advantage.

On the other hand, the US biomedical enterprise a large ship to steer. Many stakeholders have much to lose, in dollars, stature, or otherwise, from a change in the status quo. Entrenched authorities in medical training and practice may raise opposition to any type of overhaul of education or implementation of medical practice.

Speaker Contributions
Jessica Tenenbaum, PhD- Duke University
Dr. Tenenbaum is Chair of AMIA's Genomics and Translational Bioinformatics Working Group. She will frame the panel, introduce the speakers, and moderate the presentations and the discussion that follows.

David Flannery, MD, FACMG- Medical Director, ACMG
Dr. Flannery will provide an overview of the American College of Medical Genetics and Genomics (ACMG) to the AMIA membership. He will discuss current training programs accredited by the American Board of Medical Genetics and Genomics and the need for informatics as part of the training curriculum. Dr. Flannery will present some of the ACMG materials that could be adapted for clinical decision support as well as clinical research activities such as the Newborn Screening Translation Research Network and the ClinGen project.

Josh Denny, MD, MS, FACMI- Vanderbilt University
Much research in the last 5 years has demonstrated the ability to use electronic health records (EHRs) for genomic analysis. A key result from these studies is that it is possible to extract research-quality phenotypes using EHR data, but typically this is an involved and iterative process between informaticians and clinical experts. Typically, these have been with diseases, though a few studies have shown success looking at drug-response traits. We now sit with the possibility to explore deeper and more granular phenotypes, dissecting disease into a more granular and precise phenome. Dr. Denny will describe the multidisciplinary infusion of clinical expertise that will be required for continued advancement in these areas, with training in data mining, natural language processing, computational as well as classical genetics.

Douglas Fridsma, MD, PhD, FACMI- President & CEO, AMIA
As AMIA’s President and CEO, Dr. Fridsma will discuss a number of AMIA training initiatives, including the Advanced Interprofessional Informatics Certification (AIIC), AMIA’s "10 x 10" courses, the Joint Summits on Translational Bioinformatics, and other AMIA initiatives. He will offer a high level perspective on how the various initiatives tie together, and how AMIA as an organization can work with the American College of Genetics and Genomics (ACMG) to train the Precision Medicine workforce of tomorrow.

Marc S. Williams, MD- Director Genomic Medicine Institute, Geisinger Health System

Dr. Williams is one of a handful of individuals boarded in clinical genetics and clinical informatics. In his presentation, Dr. Williams will briefly compare the competencies for each certification and propose content for each of the respective certification programs that could define interprofessional training. Opportunities to co-manage and harmonize Maintenance of Certification requirements to reduce the burden on individuals boarded in both specialties will be explored. He will also briefly explore informatics training to allied genetics professionals such as genetic counselors through the proposed AIIC program.

Questions for Discussion

- What are the key competencies to include in a clinical informatics program with a genomic emphasis?
  - What are the minimal genomic competencies to include in all clinical informatics programs?
- What strengths do current training programs have in genomics/precision medicine?
- What are the key gaps in current clinical informatics training that must be addressed?
- How can interactions between bioinformatics, genetics, and clinical informatics training programs be promoted to support precision medicine?
- What opportunities exist to introduce the multi-disciplinary nature of the field early in training, e.g. at the undergraduate level and professional training, such as medical school?
- How useful/important is an MD-PhD, really?

Conclusion

AMIA is poised to make significant contributions to the Precision Medicine Initiative. It also stands to benefit significantly from strategic partnerships with complementary professional organizations like the high profile, high impact ACMG. This panel will frame both the opportunities and challenges around collaboration and cooperative education. The broader discussion is sure to serve as a launching point for a productive partnership moving forward.

Statement of participation

All panelists have agreed to attend and participate if this panel is selected for the AMIA 2015 scientific program.

Opportunities for Social Media within Consumer Health Informatics

Rupa Valdez, PhD1; Sahiti Myneni, PhD, MSE2; Andrea Hartzler, PhD3; Lena Mamykina, PhD4; Nathan Cobb, MD5; Laura Barnes, PhD6 (moderator)

1Department of Public Health Sciences, University of Virginia, Charlottesville, VA; 2University of Texas School of Biomedical Informatics at Houston, Houston, TX; 3GroupHealth Research Institute, Seattle, WA; 4Department of Biomedical Informatics, Columbia University, New York, NY; 5Georgetown University Medical School, Washington, DC; 6Department of Systems and Information Engineering, University of Virginia, Charlottesville, VA

Abstract
Social media, including blogs, wikis, discussion forums, and social networking tools, has become an increasingly significant space for health-related interactions among patients and others engaged in their care (e.g., family, friends, peers, and health professionals). This panel will address critical questions surrounding current and future opportunities for social media within consumer health informatics. Panelists will discuss their experiences analyzing health-related interactions on social media and the resulting implications for consumer health informatics design and research: Dr. Hartzler will discuss ethical considerations; Dr. Myneni will discuss use of existing theories and methods for data analysis; Dr. Valdez will discuss novel recruitment and data collection methods; Dr. Mamykina will discuss design guidance drawn from observational learning; Dr. Cobb will discuss methods of outcome measurement and inherent challenges. The session will then serve as a forum for panel and audience engagement with opportunities at the social media and consumer health informatics intersection, including: innovative research designs, strategies for safeguarding user privacy, novel methods, and the role for health professionals and other stakeholder groups in social media interactions. This panel is timely given that the rapid growth of social media for personal health management has enabled new and evolving forms of patient engagement and stakeholder collaboration.

Intended Audience
Individuals who have experience or interest in leveraging social media for consumer health informatics design and research.

Aim of the Discussion
To discuss the potential challenges, strategies, and ethical concerns associated with using social media within consumer health informatics design and research.

Overall Panel Topic
Currently, one in four Americans use social media to seek health information, while social media use in general continues to rise across all demographic groups. Although people use a range of social media for health-related purposes, two general forms are prevalent in health-related interactions: online health communities (e.g., PatientsLikeMe, CaringBridge, TuDiabetes) and general social media platforms (e.g., Facebook, Instagram, Pinterest), many of which have dedicated spaces for health-related interactions. The rapid growth of social media for personal health management has enabled new and evolving forms of patient engagement. As the emerging suite of platforms for personal health management continues to unfold, questions regarding the functions and effectiveness of social media for supporting patients provoke a multitude of responses. Therefore, the purpose of this panel is for panelists to discuss their experiences investigating health-related interactions on social media platforms and to converse with the audience about considerations and opportunities for future consumer health informatics design and research efforts.

Contribution of Each Panelist
At the start of the session, each panelist will provide a short presentation about his or her work at the intersection of social media and consumer health informatics.

Andrea Hartzler, PhD
Dr. Hartzler will focus on considerations for research ethics related to social media and the resulting implications for consumer health informatics design and research. She will differentiate types of social media by the style of collaboration and choices of research design each support, from large-scale text processing to small-scale interviews. Across research designs for studying online communities, Dr. Hartzler will contrast strategies for preserving user privacy and confidentiality in data collection and dissemination of results. By characterizing the variety of research options and ethical considerations that social media present, this presentation will facilitate discussion on understanding ethical challenges and opportunities for social media design and research in consumer health informatics.

*Sahiti Myneni, PhD, MSE*
Dr. Myneni will focus on the need to adopt and modify existing theories and methods to analyze social media data and the resulting implications for future consumer health informatics design and research. Specifically, she will address how data analysis approaches should account for scalability, granularity, and theoretical validation. The presentation will highlight the role of informatics, specifically automated text analysis techniques, in achieving balance between analytical depth and scale. Dr. Myneni will also discuss how application of behavioral change theories and social influence models may be used to examine consumer engagement in online health communities. By presenting these data analysis techniques, this presentation will facilitate discussion on how existing theories and methods may be adapted or modified to accelerate social media design and research in consumer health informatics.

*Rupa Valdez, PhD*
Dr. Valdez will focus on the opportunity for novel recruitment and data collection methods and the resulting implications for future consumer health informatics design and research. Dr. Valdez will address approaches to leveraging existing social structures embedded within social media (e.g., Facebook groups and pages) to recruit and engage participants in online versions of traditional data collection methods (e.g., interviews and surveys) and to understand participants’ perspectives on their social media-based health-related interactions. By illustrating novel recruitment and data collection methods, this presentation will encourage discussion on the need for methodological development to accelerate social media design and research in consumer health informatics.

*Lena Mamykina, PhD*
Dr. Mamykina will focus on opportunities to leverage social media to enable observational learning in the context of health and wellness through sharing of lived experiences. She will discuss recent studies of social and observational learning on such sites as Pinterest and Instagram, and will draw implications for the design and research of informatics interventions for enabling and facilitating these practices. By describing the potential for drawing design implications from social media-enabled observational learning, this presentation will stimulate discussion on translation of knowledge gained through field studies into design guidance.

*Nathan Cobb, MD*
Dr. Cobb will focus on how social features of real world, large-scale networks can lead to changes in a range of outcome measures and the resulting implications for future consumer health informatics design and research. Drawing from large scale randomized control trials conducted within online social networks, he will discuss how social processes can drive diffusion and mediate both engagement and health outcomes. He will specifically discuss evidence that diffusion of health interventions, ie viral spread, can be measured as an outcome as part of a design process of online interventions. By describing these methods this presentation will enable discussion of both traditional and alternative outcome designs and their ethical implications.

**Panel Topics**
After the introductory presentations, the panel and audience will engage in a discussion of various topics, facilitated by the moderator. Topics relevant to this panel are:

- What are the major ethical challenges to conducting social media-related consumer health informatics research and design?
- What are the major practical challenges to conducting social media-related consumer health informatics research and design?
- How do we promote research at the intersection of social media and consumer health informatics?
• How can we engage patients and other stakeholders in research and design at the intersection of social media and consumer health informatics?

• What theories can we draw on across disciplines to serve as foundations for research and design at the intersection of social media and consumer health informatics?

• What methodological innovations are necessitated by research at the intersection of social media and consumer health informatics?

• How do we effectively and efficiently translate understanding of patients’ and other stakeholders’ use of health-related social media into recommendations for consumer health informatics design?

• What are appropriate evaluation measures for consumer health informatics-related social media interventions?

After discussion of the topics above, the moderator will lead the panelists in a debate to address the following question: What are the priorities for future research and design at the intersection of social media and consumer health informatics?

Goals of the Panel Discussion
(1) Foster an interdisciplinary dialogue related to the opportunities for social media within consumer health informatics; (2) Provide AMIA symposium attendees with an understanding of the multiple ways in which they may leverage social media within consumer health informatics research and design practice; (3) Provide AMIA symposium attendees with an understanding of the current challenges and ethical dilemmas surrounding the use of social media within consumer health informatics design and research; (4) Engage AMIA symposium attendees in a collaborative discussion regarding appropriate future directions for work at the intersection of social media and consumer health informatics.

Panel Timeliness
This panel is timely because the dramatic rise in social media for personal health management has enabled new and evolving forms of patient engagement. Appropriately studying and designing to support this novel form of patient engagement requires consideration of unique ethical issues and the development of new theoretical, methodological, and translational approaches. Because of its interactive nature, this panel will serve as a forum in which audience members and panelists can collaboratively advance dialogue at the intersection of social media and consumer health informatics. Audience members will have the opportunity to learn from the panelists and one another about new developments at this intersection. The sharing of experiences stimulated by this panel will serve as a foundation for generating and prioritizing future design and research initiatives required to realize opportunities for social media in consumer health informatics.

All panelists have agreed to take part on this panel.
Health Informatics Graduate Program Accreditation: CAHIIM Process and Standards Update

Judith J. Warren, PhD, RN¹, Stephen Johnson, PhD², Suzanne Boren, PhD, MHA³, Stuart Speedie, PhD⁴, Guenter Tusch, PhD⁵

¹Warren Associates, LLC, Plattsmouth, NE, ²Cornell University, New York City, NY, ³University of Missouri School of Medicine, Columbia, MO, ⁴University of Minnesota, Minneapolis, MN, ⁵Grand Valley State University, Allendale, MI

Abstract
Academic program accreditation in higher education is both a process and a status involving a review of a program against formal Standards to determine educational quality, how well students and society are served, and if successful the award of accreditation. The Commission on Accreditation for Health Informatics and Information Management Education (CAHIIM) has offered accreditation at the masters’ degree level in Health Informatics since 2010. AMIA officially joined CAHIIM as a Member organization in January 1, 2015. A revision in the governance structure created a Health Informatics Accreditation Council with the responsibility of establishing and maintaining accreditation Standards, policies and procedures. This Panel will present the Council’s work to date and address questions about how CAHIIM accreditation is conducted, the value of accreditation to the health informatics field, the status of goals for 2015-2016, how the process is conducted, and the types of CAHIIM volunteer opportunities. Participants will have the opportunity to ask questions and provide input on the Council’s initiatives from their varied perspectives.

Introduction
Academic program accreditation in higher education is both a process and a status involving a review of a program against formal Standards to determine educational quality, how well students and society are served, and if successful the award of accreditation. The Commission on Accreditation for Health Informatics and Information Management Education (CAHIIM) has offered accreditation at the masters’ degree level in Health Informatics since 2010. CAHIIM is a recognized accreditation organization by the Council for Higher Education Accreditation (CHEA). Effective January 1, 2015, AMIA joined CAHIIM as an official Member organization of CAHIIM and a revision in the governance structure has provided new opportunities for volunteers to participate.

Aims of Discussion
Judith J. Warren, PhD, RN, FAAN, FACMI will introduce the Commission on Accreditation for Health Informatics and Information Management Education (CAHIIM) structure and the Health Informatics Accreditation Council. Volunteers and staff supporting the CAHIIM organization from early discussions to the present, in the audience will be recognized including the CAHIIM Board of Directors. She will elaborate on the scope of CAHIIM Health Informatics accreditation, the volunteer appointment process and the criteria to serve on the Panel of Accreditation Reviewers who conduct the site visits and prepare summary reports to CAHIIM.

Stuart Speedie, PhD will provide a brief overview of the journey AMIA has taken to collaborate with CAHIIM, why the need for accreditation of graduate health informatics programs was determined, and the value proposition that comes from a defined academic program accreditation process. He will briefly remark on any revisions to the Standards for Accreditation of Health Informatics Master’s Degree Programs and the timeline for implementation, as a recent responsibility of the Health Informatics Accreditation Council.
Stephen Johnson, PhD, FACMI will address the Health Informatics Competencies Framework project, program outreach through recent webinars and comments to date, as well as the next steps and timeline to implementation. The impact of a set of core competencies to the health informatics professional community is a significant step in public recognition of this academic discipline.

Suzanne Boren, PhD, MHA will share practical experiences with her institution’s Health Informatics master’s degree program as it currently moves through the self-assessment phase of the accreditation process. She will share several practical tips on preparation and documentation requirements.

Guenter Tusch, PhD, will moderate the panel of presenters and field audience questions at the conclusion of the presentations. CAHIIM staff will be present to address any questions on CAHIIM fundamentals, policies, and procedures related to the Health Informatics accreditation process.

Significant time will be allocated to a question and answer period giving the audience an opportunity to reflect on the progress made, and to share ideas and perspectives on the health informatics accreditation process with the Council and staff. An added dimension will be an opportunity for audience comments on any proposed revisions to the 2010 Accreditation Standards for Health Informatics Masters Degree Programs and the Competencies Framework that will have been made available to the AMIA membership in advance of the November conference.

**Conclusion**

Accreditation of health informatics graduate programs is essential to ensure a supply of highly qualified professionals in the healthcare field able to address the growing needs of information technology applied to all realms of healthcare delivery. Progress towards this goal has been made with the partnership of AMIA as an organization Member of CAHIIM. This interactive session is an opportunity for the audience to become involved in the value discussion, and to provide direct input into the CAHIIM Health Informatics Accreditation Council, Board and staff as it moves forward to update Standards, professional competencies, and procedures to meet the needs of an evolving and growing professional discipline.

Career Opportunities for the Many Paths to Informatics

Laura Wiley, MS1, Tiffany Kelley, PhD, MBA, RN2, Virginia Lorenzi, MS3, Vishnu Mohan, MD4, Jessica Tenenbaum, PhD5, Julie Doberne4
1Vanderbilt University, Nashville, TN, 2Nightingale Apps, Boston, MA, 3Columbia University, New York, NY, 4Oregon Health and Science University, Portland, OR, 5Duke University, Durham, NC

Abstract
Informatics is a diverse field with an even more diverse workforce. A demand for informatics professionals continues to increase, the number and types of informatics training opportunities also increase. From traditional informatics training programs to cross-training in informatics and informatics certification programs, there are a number of ways into an informatics career. Following our successful tradition, the AMIA Student Working Group proposes a “career panel” to offer perspectives and advice for students on career opportunities and professional development. This year, the panelists include a board certified physician informatician, an informatics PhD working in academia, a cross-trained PhD-level informatician entrepreneur and a certified informatics professional with industry and academic experience. They will share their career and educational experiences and discuss upcoming trends in informatics careers. This panel will help future and current informatics students and early-career professionals to better prepare for and develop their careers.

General Description
The Student Working Group (ST-WG) of the American Medical Informatics Association (AMIA) annually organizes a career oriented panel at the AMIA Fall Symposium to provide students with important perspectives and advice on career opportunities in informatics. In place since 2002, these panels have had various themes including the career stages of informaticians (2012), careers in academia vs industry (2013) and emerging informatics careers (2014). These panels are routinely well attended and serve as a highlight for student attendees.

Career opportunities for informaticians are growing exponentially and it is clear that there are a variety of training mechanisms available to individuals interested in the field. From traditional Masters and Doctorate informatics training programs to the new American Board of Preventive Medicine (ABPM) Clinical Informatics Subspecialty Fellowships, there are a variety of formal informatics training options. Additionally, due to the diversity of informatics a number of informaticians have training in another discipline with extensive informatics experience and expertise but without a formal informatics degree. There are also a number of informatics certifications from the aforementioned ABPM Subspecialty to Certified Associates/Professionals in Healthcare Information and Management Systems (CAHIMS/CPHIMS). This panel will feature speakers with diverse career and informatics training experiences to give both current and prospective students insight into career opportunities across a variety of types of informatics training.
This year we will build on our successful tradition and enhance it in the following ways:

(a) Feature panelists who have a variety of educational experiences in informatics including formal and informal informatics training
(b) Feature panelists who hold a variety of certifications including: CPHIMS and the recent ABPM Clinical Informatics Subspecialty.
(c) Cover a variety of career types from traditional tenure-track academics, to other academic and business/entrepreneurial roles.
(d) Provide a mixture of domain experiences from clinical informatics, bioinformatics and nursing informatics

In response to the large number of questions typically received at this event, we plan to take advantage of the new interactive panel format. Each of the panelists will have 5 minutes to introduce their educational and career background. The remainder of the session time will be allotted to audience and moderator driven discussion questions. Potential topics for discussion include:

(a) How has your educational training prepared you for your career?
(b) What influenced your decision to enter into the field of informatics and pursue your informatics training?
(c) How should students prepare and ready themselves for the coming career opportunities and trends?
(d) How should early career informatics graduates continue to improve their skills and be successful in their careers?

Given the different career experience and education background of the panelists, this panel will provide valuable perspectives for professional, PhD and master students, as well as those just entering the field and determining which educational path is best for their informatics career.

Organizers

Statement
I, Laura Wiley, confirm that all panelists listed in this proposal have agreed to participate in this panel. Panelists are aware that there are no travel or registration funds available. Panelists are also aware that the Student Working Group is unable to reimburse their registration costs.
An Interactive User Interface for Drug Labeling to Improve Readability and Decision-Making

Hamed Abedtash¹, PharmD, Jon D. Duke, MD, MSc²

¹School of Informatics and Computing, Indiana University, Indianapolis, IN; ²Regenstrief Institute, Indianapolis, IN

Abstract

FDA-approved prescribing information (also known as product labeling or labels) contain critical safety information for health care professionals. Drug labels have often been criticized, however, for being overly complex, difficult to read, and rife with overwarning, leading to high cognitive load. In this project, we aimed to improve the usability of drug labels by increasing the ‘signal-to-noise ratio’ and providing meaningful information to care providers based on patient-specific comorbidities and concomitant medications. In the current paper, we describe the design process and resulting web application, known as myDrugLabel. Using the Structured Product Label documents as a base, we describe the process of label personalization, readability improvements, and integration of diverse evidence sources, including the medical literature from PubMed, pharmacovigilance reports from FDA adverse event reporting system (FAERS), and social media signals directly into the label.

Introduction

Food and Drug Administration (FDA) prescribing information (also known as product labeling or labels) are primarily meant to be used by physicians and other healthcare professionals to find accurate, reliable drug information needed to prescribe medicines safely and effectively. The labeling provides evidence-based information on adverse reactions, contraindications, dosing modifications in children and the elderly, and guidance regarding use in pregnancy and nursing¹. However, labels have also been extensively criticized for having too much information, making them complex, lengthy, and challenging to readers seeking relevant and important safety warnings²-⁴. In our previous quantitative analysis³, we found the “overwarning” problem with the adverse drug events (ADE) in the labeling content which hinders clinicians from grasping the significant safety alerts in the labels.

When reviewing a drug label, health-care providers must scan the entire label content to find relevant safety warnings, a cumbersome and time consuming task. While the introduction of label Highlights has brought some of this information to the fore, these facts are limited to the most severe or frequent events in the overall population, without consideration of patient-specific factors. Providers utilizing labels are most commonly seeking a particular piece of information related to a particular patient, whether based on co-morbidities, co-medications, or symptoms that have been raised in a visit. Finding such information with a label is inefficient and often impossible within the time constraints of a typical office visit. There are, of course, myriad websites and applications that provide drug safety information. However, the FDA-approved label is unique—it is thoroughly vetted and approved by a standardized process, and is recognized by manufacturers as the defining statement regarding their drugs. Thus, working with the actual label to improve its usability is a necessary and novel advancement in providing a better experience for providers while maintaining the ‘blessing’ of manufacturers and the FDA.

In this paper, we describe the development of an interactive, web-based application known as myDrugLabel. The goals of this project were to 1) improve the readability of FDA-approved drug labels by increasing the ‘signal-to-noise ratio’, 2) provide meaningful information to the physicians based on patient-specific comorbidities and concomitant medications, and 3) support the decision-making process by integrating additional evidence sources (e.g., medical literature, pharmacovigilance reporting, social media signals) directly into the label. In the following sections, we will provide an overview of the application design process and walk through the resulting application’s architecture and features through a sample clinical scenario.

Methods

Requirements and Design

We applied an iterative design process to prototype, develop, and refine the application components including data processing algorithms, user interface, and database. In each iteration, the developed functionalities were tested and necessary modifications were made. Healthcare professionals, e.g., physicians, pharmacists, and nurses were identified as target users of the application with a possible extension to patients as we add enhanced usability.
In the first step, the functional requirements of the application were elicited through a group composed of one physician and two pharmacists (including authors HA and JD) to define use cases and task scenarios. Figure 1 represents the use cases defined by this group, including label searching, modification of patient-specific factors, and integration of data from multiple sources. The requirements called for five data ‘providers’, the user and four external Application Program Interfaces (APIs), i.e. RxNORM, PubMed, FDA Adverse Event Reporting System (FAERS), and Topsy. The diagram represents the functional requirements for the system and the interactions between actors (e.g., user) and use cases (e.g., search a drug label). The “include relation” indicates that the included use cases are part of a larger use case and executed upon parent use case is called. The “use relation” or large hollow triangle arrow shows that the process of doing a use case (e.g., Customize Drug Label) always involves executing another use case (e.g., Add/Change Age).

Figure 1. Use case diagram of myDrugLabel application. The “include relation” specifies that the use cases are executed as part of a parent use case, and the “use relation” or large hollow triangle arrow indicates that execution of the base use case involves performing another use case. API=application program interface, FAERS=FDA adverse event reporting system, SPL=structured product labeling.

In the next phase, prototypes of the user interface were developed based on these requirements. Both designs had data entry sections on the left side; however, the design with a simpler interface in which supplementary information was displayed in tooltips above the highlighted terms was felt to be a better experience by the test users. The prototypes were evaluated by external users, and changes were made to the prototype interface based on the comments.

Technology Platforms

The proposed architecture was based on standard medical terminologies, open-source software and database platforms, and publicly available application programming interfaces (APIs). RxNORM® and MedDRA® (Medical Dictionary for Regulatory Activities) were used to map drug names and adverse events within the drug labels,
respectively. HTML5, CSS3, JavaScript, jQuery library, and AJAX were used to develop interactive webpages with asynchronous data transfer capability. Data were requested and transferred via PHP (server-side language for web application development) APIs from a MySQL database in extensible markup language (XML) or JavaScript Object Notation (JSON) formats.

Structured Product Labeling (SPL)

Structured Product Labeling (SPL) is the standard format accepted by FDA for transferring drug labeling contents between information systems. FDA drug labels were retrieved in SPL format from DailyMed and transformed to HTML files using the latest SPL schema available on FDA website, retrieved on October 14, 2013.

Processed SPL (P-SPL) Documents

In order to improve the performance of filtering label contents by diseases and comorbidities, a Python application was developed that identified adverse event terms in the SPL based on MedDRA hierarchy using simple natural language processing (NLP) and regular expression techniques to encapsulate in a span HTML tag. This approach saved time and decreased CPU load for the client facing interface. For example, the term 'myalgia' in the SPL was converted to `<span class="condition" mdrptid="36516837">myalgia</span>`. This modification allowed for rapid manipulation of the visual design of the label based on user input, without needing to search for terms in real-time (i.e., user waiting time). The response time highly depends on the client system configuration, length of the drug label, and how many times the term is mentioned in the label content. In average, the modification reduced the user waiting time from 60 to 2 seconds on a Desktop PC with CPU i5-3470 3.3 GHZ and RAM of 4MB.

Supplemental Evidence and Information

One of the recognized challenges to interpreting adverse events in drug labels is the lack of external evidence. For example, is an event listed simply because it was reported to the FDA, or have there been substantive studies exploring the associated risk between drug and event? We thus sought to supplement the labels with additional external evidence sources, displayed in a tooltip after selecting a drug adverse reaction or drug name. This was accomplished through the use of APIs pulling in data from the literature (PubMed API), the FDA adverse event reporting system (FAERS) (openFDA API), and Twitter posts (Topsy API). The information was streamed via respective APIs in a real-time manner.

FAERS data were retrieved from openFDA platform launched in June 2014. The queries to the API comprised two sections. In the case when an adverse reaction is selected on the label, the label’s drug name along with the MedDRA preferred term of the reaction are concatenated. Throughout our preliminary testing the API, we learned that both generic name and brand name of the drug should be in the query to fetch all records. For example:

Likewise, when a drug name on the label is selected, the chosen drug name and the drug label’s name are sent to API. The returned counts do not necessarily indicate the number of drug-drug interaction events. For example:

Results

Application Architecture

The architecture of myDrugLabel is a Service Oriented Architecture (SOA) design in which the client- and server-side components are connected via RESTful web services with the server database and external APIs (Figure 2). The client-side includes webpages, JavaScript codes, and P-SPL document. The server-side component is composed of a database, the bank of P-SPL documents, and PHP APIs.

The application has two pages, Home and Label View. The user starts looking up a drug name on Home page to select a drug of interest. Then, the page navigates to Label View page to display the labeling content and filtering functionality. In order to maximize speed of the client-side user interface, all data transfer processes between the server and browser are done in an asynchronous fashion. The only exception is when the drug labeling content is retrieved from the server. On the Home page, a request is sent asynchronously to the API once the user searches a
drug name, then the top 10 drug names similar to the input string are returned to fill the drop down list. Selecting the drug name directs user to the Label View page, which is the main page for processing the labeling content. The selected drug’s P-SPL document is loaded from server via the SPL Loader API and gets transformed to an HTML file by using the FDA-provided XSLT schema.

The application does not have a stand-alone business layer. Part of the calculations and text processing are performed on the client browser by JavaScript functions, including highlighting or hiding content sections, terms, displaying notifications on the right side, and tooltip functionality. Some other processes that needed security constraints, such as database connections and external API data transfer were designed to be performed by the server-side PHP APIs. The server APIs include SPL Loader (fetches SPLs from server by the requested SPL ID), Drug List Retriever (gets drugs lists from the database), MedDRA Checker (returns comorbidities’ synonyms from MedDRA dictionary located in the database), PubMed Retriever (requests and processes the literature statistics from PubMed), FAERS Retriever (requests and returns ADE statistics from FAERS), and Topsy Retriever (requests, calculates, and returned the number of signals on Twitter).

![Simplified view of myDrugLabel architecture](image)

**Figure 2.** Simplified view of myDrugLabel architecture. AJAX=asynchronous JavaScript and XML, API=application program interface, FAERS=FDA adverse event reporting system, MedDRA=medical dictionary for regulatory activities, PHP=server-side language for web application development, SPL=structured product labeling.

**Application User Interface**

Once a drug is selected from the Home page (Figure 3), the page is directed to Label View page (Figure 4), which is the primary location for interactivity in the application. On this page, the user can enter patient-specific parameters, which dynamically alter the labeling content (Figure 4, section A). For example, if the patient’s age is greater than 65 years old, the geriatrics section is automatically highlighted and the pediatrics sections is become hidden. Similarly, upon selection of male gender, the pregnancy and nursing sections are hidden. Making these adjustments enhances the readability of the label by reducing unnecessary content. Similarly, when a patient condition is added,
all synonyms of the disease are retrieved via the MedDRA API and highlighted in the label text (Figure 4, section B). Highlighting of conditions is limited to the following safety-related sections: Adverse reactions, boxed warnings, clinical studies, contraindications, warnings and precautions, general precautions, other safety information, pregnancy, risks, use in specific populations, and user safety warnings.

Figure 3. Home page of myDrugLabel application. User searches for a drug name in the provided textbox; once a drug is selected, it directs to Label View page.

To the immediate right of the label content is a customized navigation bar (Figure 4, section C) that provides quick access to highlighted sections of the label (based on patient parameters, such as pregnancy information or geriatric dosing instructions). The navigation bar also provides rapid access to highlighted terms within the label, such as relevant conditions, medications, and adverse effects. To help the user keep track of this content, related concepts are color coded throughout both the content and the navigation areas. Thus, for instance, if the user enters a condition of ‘Myalgia’, all information related to the condition will be highlighted in the same color throughout the document. Myalgia-specific highlights can then be toggled on and off as a group. For certain sections, color-coding is applied in standard fashion for all labels. For example, the pregnancy and nursing sections are highlighted in pink.

Integrated evidence from external data sources was shown via on-demand tooltips, for better accessibility and to avoid information overload. The tooltips are accessible by clicking on any highlighted term, either comorbidities or co-medications. The tooltip is composed of four tabs (Figure 5), including an evidence overview, literature data, pharmacovigilance reporting data, and social media signals. The overview tab gives the user a general sense of the strength of association between the selected term (comorbidity or co-medication) and the drug of interest. On the literature tab, the statistics of published papers mentioning both the drug (generic and brand) and the condition or its synonyms are presented stratified by type of publication, including journal article, case reports, clinical trials, controlled clinical trials, meta-analyses, observational studies, randomized controlled trials, and review articles. The link to PubMed search page is also provided, which will take the user to a new window containing the PubMed search results specific for that drug, condition, and article type.

The ADR reports tab displays how often the comorbidity or co-medication has been reported by other consumers of the drug of interest. These reports are divided into categories based on seriousness: 1) congenital anomaly, 2) disabling, 3) hospitalization-associated, 4) life-threatening, 5) death, 6) all serious events, and 7) all non-serious events. The social media tab provides real-time data on mentions of the drug and condition of interest (or its synonyms) on Twitter. The number of posts are grouped by 1-day, 7-day, 30-day, 6-month, and 1-year time frames.

Usage Scenario

An example scenario for myDrugLabel is demonstrated in Figure 4. A 71-year old woman is taking Lipitor for her hypercholesterolemia. She has also other comorbidities including diabetes, myalgia, hypertension, and heartburn for...
which she is taking acetaminophen, metformin, hydrochlorothiazide, and cimetidine. After the patient data is entered, the sections related to geriatrics turn to green, while pediatrics, pregnancy care, and nursing sections are hidden. The numbers next to the comorbidities and co-medications on the filter and notification bars show how many times they are mentioned in the label’s content. As shown in the figure, the sections that contain the terms are highlighted such as warnings, precautions, adverse events, and clinical trials, making it easy to find the relevant information specific to a particular co-morbidity or symptom.

![Image]

**Figure 4.** The Label View page. Using the filter box (A), user is able to customize the label content (B) by entering age, gender, pregnancy and nursing status, comorbidities and co-medications on the left side. On the right side (C), the user is notified of found sections and terms related to the input data. The navigation (D) bar helps user jump quickly to the point of interest within the content.

**Discussion and Future Directions**

In this project, we designed, prototyped, and developed an interactive user interface for FDA-approved drug labeling called myDrugLabel, reflecting the “personalized” aspect of the application. This web-based application promises improvement in readability of drug labeling and support for evidence-based decision-making. A formal evaluation study of the tool is underway. However, it has several novel features in its architecture and visual design. First, it utilizes the original FDA-approved product label as a base for all enhancements, injecting personalized highlighting.
and multiple external evidence sources into the original labeled content. As a result, the user can review the original
label, exactly as FDA approved, or by entering a few patient parameters, review a shorter, focused document
highlighting the specific areas of interest to the practitioner.

MyDrugLabel incorporates a number of existing APIs to pull real-time data from evidence sources, then further
stratifies this information to maximize usability. Most critically, myDrugLabel assists the provider in determining
whether a labeled side effect, potentially one of hundreds listed, is in fact supported by other sources. This
knowledge is critical to informing both the patient and prescribing decisions.

At the time of developing the website, the SPL information were accessible on the National Library of Medicine’s
Download Labels site (DailyMed). In August 2014, openFDA released drug product label API
(https://open.fda.gov/drug/label/) that provides access to over 25,000 prescription and 36,000 over-the-counter
(OTC) structured product labeling records. The new API has three main advantages. First, SPL information can be
retrieved with high level of granularity, meaning that the user has the option to download pieces of the label, e.g.,
Boxed Warning, Adverse Reactions, Drug Interactions, Patient Counseling Information, etc. Second, it is possible to
perform simple SPL mining using the API, for instance, to find the medications that have a specific ingredient or
adverse reaction. Third, the API has the power to perform a descriptive analysis, e.g., to identify the number of
products having a specific food interaction with alcohol or grapefruit juice. Considering these capabilities, the new
iterations of myDrugLabel will be a proper showcase of applying openFDA drug product label API.

A limitation of this paper is the lack of usability metrics to quantify the benefits experienced by users of this tool.
However, many of myDrugLabel’s features, such as simply removing pregnancy information from labeling for male
patients, shows the intuitive benefits of its design. Another limitation is that the presence of abstracts in the literature
or mentions on Twitter do not necessarily imply a causal or direct association between drug and effect. The search
strategies for these sources need to be refined to better interpret the evidence for users of the application.

Several next steps are planned for the development and evaluation of the application. First, as mentioned, we will
evaluate the application with healthcare professionals from different specialties as well as patient users. Secondly,
we will incorporate evidence from observational data networks to provide more clinically sound evidence of
associations between drug and adverse events. Finally, myDrugLabel will be released for public use, both to gather
feedback on larger scale and to incorporate patient-reported adverse effects into the evidence base.
Figure 5. The tooltip element provides supplementary information about conditions and co-medications. A) The Overview tab shows total number of items in each evidence section group. B) The Literature tab presents a stratified count of papers in the literature citing both the drug of interest and the selected term. C) The ADR Reports tab shows the number of reported cases associated with the drug and selected condition. D) The Social Media tab provides the count of Twitter posts mentioning the specific term (or its synonyms) and the drug of interest.

Abstract

Drug-Drug Interactions (DDI) are an important source of preventable adverse drug events and a common reason for hospitalization among patients on multiple drug therapy regimens. DDI information systems are important patient safety tools with the capacity to identify and warn health professionals of clinically significant DDI risk. While substantial research has been completed on DDI information systems in professional settings such as community, hospital, and independent pharmacies; there has been limited research on DDI systems offered through online websites directly for use by ambulatory patients. The focus of this project is to test patient oriented website capacity to correctly identify drug interactions among well established and clinically significant medication combinations and convey clinical risk data to patients. The patient education capability was assessed by evaluating website Information Capacity, Patient Usability and Readability. The study results indicate that the majority of websites identified which met the inclusion and exclusion criteria operated similarly, but vary in risk severity assessment and are not optimally patient oriented to effectively deliver risk information. The limited quality of information and complex medical term content complicate DDI risk data conveyance and the sites may not provide optimal information delivery to allow medication consumers to understand and manage their medication regimens.

Introduction

Adverse drug events, including injury and death, have been reported to affect up to 1.5 million patients annually, according to an Institute of Medicine report on Preventing Medication Errors. Exact numbers are difficult to assess, due to lack of uniform reporting, but adverse drug events are estimated to add 2-4 days to hospital length of stay at a cost of $2500-$5500 per patient1,2,3. A particular subset of adverse drug events, drug-drug interactions, occur frequently among community and ambulatory care settings with estimates on patient risk of exposures to drug-drug interactions ranging from 2.2% up to 70% of patients, depending on the population studied and the methods used in the study.4,5

Drug-Drug Interaction (DDI) information systems are essential tools to identify medication combinations which may place patients at risk of adverse drug events (ADE) including the potential risk of major morbidity and mortality6. DDI information systems have the capacity to help identify, analyze, and facilitate the avoidance of potentially dangerous or even lethal drug interactions both as stand-alone applications or as integrated decision support in electronic medical record systems. The availability of DDI systems to health professionals includes clinical databases, DDI assessment systems, web-based tools and clinical phone applications that evaluate patient risk via information delivery and clinical decision support7,8,9,10.

Clinical content on websites provide easy access points for patients or drug consumers to efficiently gather the necessary information to understand medication therapy concerns. However, if patients receive clinical information which lacks important clinical context they may be at risk of potentially unwanted adverse drug events due to the lack of information or inaccurate information. According to the Food and Drug Administration in the year 2012, more than 325,000 serious health outcomes and 54,000 deaths resulted from ADE, providing an important concern on the safe delivery of medications in healthcare11. With the estimated prevalence of DDI mediated ADE varying widely, it is not well established as to what percentage of ADE are directly associated with drug interactions, however, the DDI are a major clinical concern and patient safety opportunity since many of the DDI-mediated ADE are potentially preventable.

Patient oriented DDI Information systems are publically available computer databases available via websites, which have been created to inform patients and drug consumers about relevant drug interactions to help drug consumers...
stay informed on their medications and assist in ADE prevention. The typical clinical provider-oriented DDI
information systems provide information on potential DDI, drug-food interactions, or even drug-alcohol interactions
to help the clinician understand potential risk. The purpose of this study is to assess whether free and publically
available patient-oriented DDI assessment websites function in similar ways and contain accurate and reliable
information concerning DDI risk. Furthermore, the study will assess if these publically available websites contain
DDI risk content which is patient oriented in the risk communication information content (multimodal with graphics
and risk cues) and the required reading level for the estimated risk information (6-8th grade reading level).

Background

Current DDI information systems exist primarily in professional settings such as community and hospital
pharmacies and electronic prescribing systems for use in clinical decision support by medication prescribers and
dispensers. The presence of information systems has been successful in identifying potential DDI exposures at the
point of care. In an extended study done by Abarca et al., the study evaluated the performance of DDI screening
software in identifying clinically significant DDIs in pharmacy computer systems in community and hospital
pharmacies. They used 25 medications with a total of 37 drug pairs and 16 clinically significant drug pairs to create
6 mock patient profiles.12 Although there are improvements in the DDI screening systems, additional aspects needed
to be addressed included the ability to correctly detect clinically significant DDI in hospitals and understand the
exact severity of the potential interactions13. Later assessment of clinical pharmacy systems also show some
concerns still persist in DDI evaluation in the pharmacy setting.14

DDI information systems are common in pharmacies; however the data from these DDI information systems must
also interface with information systems from Pharmacy Benefit Management (PBM) companies and electronic
prescribing software15. In research work focused on the prescription claims data base of a PBM company, Malone et
al. performed a retrospective cross-sectional analysis of 46 million participants for 25 clinically potential significant
DDIs.16 The study covered a 25 month time frame and showed that an estimated 374,000 participants may have been
exposed to clinically important DDIs. The study also showed higher potential DDIs for individuals based on gender
and age differences. These results indicate that even with the presence of available information systems for DDI
risk screening, patients may still end up using at-risk medication combinations.

In assessing potential DDI risk, scoring systems have been developed to identify the severity of the potential DDI.
Prior work by Oshikoya et al. determined drug-drug interactions and severity ratings for patients with the human
immunodeficiency virus. They categorized drug-drug interactions and assigned a score on a scale of A (no known
interaction); B (minor/no action needed); C (moderate/monitor therapy); D (major/therapy modification); and X
(contraindicated/avoid combination).17 In addition, their results showed discrepancies between databases used such
as Medscape and USA MIMS. Having a means to score the potential DDI risk is needed for clinical decision
making to weigh the potential risks and benefits of medication combinations.

Previous efforts have indicated a lack of effective DDI software screening in the pharmacy setting and limited
ability to avoid clinically significant DDIs with PBM care delivery. Even with this knowledge, there has been a lack
of research focused on the DDI mediated adverse drug effects in the outpatient setting. The research approach is an
evaluation of publically available information for patient and/or caregivers concerning DDI. The goal of the study is
to analyze individual websites and determine if currently available information is valid and accurate with regards to
clinically significant DDI for drug consumers. The approach of the our research follows a similar approach to
Oshikoya17 in classifying variations that may exist between information content concerning severity ratings of
important DDI from the project websites. The significance of this research is to determine if the DDI information
offered to the general population has plausible clinical risk assessment guidance and provides the necessary
information to identify clinically significant DDIs. As previous research has highlighted, discrepancies in DDI
screening systems are present in both pharmacies as well as PBMs, this research work aims to assess for variations
in the information given to consumers about DDI risk.
**Methods**

**DDI websites.** The study focused on identifying available websites which had the capacity to inform medication consumers on potential DDI risk and were freely available to medication consumers. A total of 65 eligible websites were identified with expert selection and the search engine Google using search terms including drug-drug interaction, drug-drug interaction checker and drug-drug interaction assessment search terms. The search engine identified sites were supplemented with additional websites identified by expert informaticists and clinical practitioners. The majority of the sites were identified from the Google search effort. The identified sites were found and confirmed to be online and available during the July to September 2014 time period of primary data collection.

*Inclusion Criteria:* Websites were included in the study sample if they were freely available to external end-users with direct access to the site or with the use of an input email address for user authentication and potential use for profile tracking. English language sites were included in the study group.

*Exclusion Criteria:* The necessity for payment information or the lack of DDI checking functionality resulted in study exclusion. The websites must also have each of the clinically significant DDI medications available in their databases at the drug level. If the level of drug matching was only available at the therapeutic class level, the websites were excluded. All non-English language sites were excluded from the study. A total of 44 websites were included in the study after applying the inclusion and exclusion criteria.

**DDI medication selection.** The drug combinations in this descriptive, cross-sectional analysis of online DDI websites included a total of eight drugs and five DDI pairs which incorporated medications for multiple disease states (e.g. high cholesterol, fungal infection, etc.) to provide relatively broad medication coverage of key therapeutic areas at potential risk of DDI events (Table 1). The clinically significant DDI drug pairs were selected based on the previously published literature\(^1\) which was developed from expert consensus and large database validation. The selected medication combinations included high risk, high prevalence and potentially preventable drug combinations which could be expected to put patients at risk of adverse events. The presence of alerts for therapeutic class duplication was also measured through the Selegiline-Phenelzine drug pair to identify sites having the ability to assess multiple drug profiles where all the medications in the study set were built into a comprehensive drug profile. Some websites did not have multiple drug assessment (3 or more medication) capacity and could only assess binary medication pairs. Since all the drug pairs have been well established to be clinically significant DDI, it was expected that each should provide an alert when entered into the websites with similar estimated severity risk.

For website data entry, the medications were recognized by the generic name as well as brand names and could be recognized as an oral tablet or oral solution in regards to the route of medication. All websites included in the study were able to correctly identify either the generic or brand name of each drug for the interaction assessment.

**Data Collection**

The DDI website information performance was assessed for clinical content and patient usability. The first method assessed the clinical content of DDI information system severity ratings offered to patients. Each website visited was noted for the presence or absence of a DDI severity rating. Four ratings were identified including contraindicated, major, moderate, or minor interactions. In cases where there was not a specific standard definition on the website, a normalized approximation of the standard score was identified from the DDI data and mapped to the four level standard. The patient oriented data assessment included information capacity scores, patient usability, and readability.
**DDI Information Capacity Score:** For the information capacity score, each website was quantitatively graded on the criteria including: presence or absence of a drug-drug interaction alert, presence or absence of severity grading, severity rating scales explanation, presence or absence of drug-food interaction, presence and absence of drug-alcohol interaction and therapeutic duplication. Each website that contained the complete information in regards to each of the five drug pairs for each of the categories received points. The websites were graded with five points in three categories; DDI presence, severity rating, and drug-food interaction. Another area graded, Drug-alcohol interaction, received a max of four points (one for each drug pair), however, because the drug pair simvastatin and itraconazole are recognized to have limited interactions with alcohol it was excluded from the scoring. The last category scoring was for therapeutic duplication which received a maximum score of two points. The first point identified whether the sight was able to identify the duplication in drug therapy class and a second point for identifying the drug classes which were responsible. This point scale was used to determine the information capacity of the website and had a maximum total of 21 possible points. A summary of the scoring rubric for the DDI Information Capacity score is noted in Table 2.

**Patient Usability:** The patient usability score focused on how a consumer would approach a DDI assessment website and how they would assess if the content was patient friendly and contained clinically useful features. Ideally these features were present and represented best practices for drug information management and patient risk communication. One point was received in categories for alert icons, color coding, and severity rating scale presence, medication pick list, and login/profile management for a total of 5 possible points. Alert icons are important as they serve as a more universal image of communication which could help patients understand risk even if language barriers or reading level of the patient was limited. Color coding can help to differentiate severity data, with typical use of the color red being associated with danger and green lights associated with low risk. Severity rating scale data was deemed important in determining how dangerous a DDI exposure is to the patient. Medication pick lists are crucial for the accuracy of navigating and identifying correct drug interactions for the drug consumer. Having login/profile management for multiple drugs allows the user to easily remember the drugs they’ve searched and avoid the inconvenience of having to re-enter a long list of medications. All of these features provided grading parameters for the patient usability scores. Half points were received if the website failed to provide these features for all five drug pairs but had the functionality of some drugs. For most websites, these features were all or none phenomena and would work or not work for all of the drug pairs.

**Patient Readability:** Patient readability was determined through the Flesch-Kincaid grading model. This grading model was established by Rudolph Flesch and Peter Kincaid based on the understanding that information is more understandable with fewer words and shorter sentences. The content of information for the simvastatin and itraconazole interaction for each website was the only information content which was graded for readability. The content relevant to the drug consumer was assessed using the Microsoft 2010 Flesch Kincaid scoring assessment. Due to the potential for the commercial or generic drug names to affect this grading model, each of the drug names were replaced with the generic word “drug” instead of simvastatin and itraconazole to decrease the grade levels that would have been achieved with those words in the consumer content. The Flesch Reading Ease score was also assessed for each of the sites to provide additional measures on readability.
Results

Severity Grading

The severity ratings measured from the websites demonstrated substantial variation. Approximately half of the websites did not provide severity rating for any of the drug categories. Although a substantial sub-population of the websites failed to give severity ratings, some indicated severity levels for the five drug pairs. For sites with severity ratings, about 50% indicated a moderate severity for the drug pair Warfarin-Gemfibrozil and the other 50% indicated a major severity for the same drug pair. For the Warfarin-Levothyroxine drug pair, 14 of the 44 drug pairs indicated a moderate risk associated with these two drugs while 5 of the 44 websites indicated that this drug pair had a major risk. For the Fluoxetine-Selegiline drug combinations, 12 websites noted that the interaction was contraindicated while five websites noted that it was a major severity reaction and one website noted that it was a moderate reaction. For the Selegiline-Phenelzine drug combination, nine websites noted that this drug pair was contraindicated; three websites noted that it was a major reaction, and one website noted that it was a moderate reaction. The DDI severity data is summarized in Figure 1.

Figure 1: Drug-Drug Interaction Severity Frequency

Information Capacity Scoring

Among the 44 websites included in this research, the mean Information Capacity score was 13.36 points with a standard deviation of 3.09 points. The highest scoring website had a score of 21, which was the maximum possible score. Two websites scored 19, which was just below the maximum possible scores. The lowest scoring website had a score of 4 and the second lowest score belonged to three other websites with a total score of 8 each. 42 of the 44 websites lacked the Therapeutic Duplication feature. The results for all the DDI Information Capacity scores are noted in Figure 2.
**Patient Usability Scoring**

The average score for the Patient Usability score for all 44 websites was 2.9 points with a standard deviation of 1.06 points. The distribution of the scores is noted in Figure 3. Only five websites received perfect scores for patient usability scoring. The scores that received half a point for some information features failed to have that specific feature for all drug pairs. The most common features for half points given were alert icons and severity rating scales.

Figure 3: Patient Usability Scores
**Website Readability Scoring**

The average Flesch-Kincaid grade level scored was 11.2 with the highest grade level being 16.2, the lowest grade level being 6.7 and a standard deviation of 2.29 with the results summarized in Figure 4. The Flesch Reading Ease score was also measured for the 44 websites was 40.27 with the highest score being 70.9, the lowest score being zero and the standard deviation being 15.11 with the results summarized in Figure 5.

![Figure 4: Reading Level of DDI websites](image)

**Grade Level Required To Understand Website Content**

![Figure 5: Website Reading Ease Measures](image)

**Flesch Reading Ease Scores**
Information on Drug-Drug Pairs Identified

Of the five drug pairs included in this study, three drug-drug interactions were not correctly identified by all of the DDI checkers. The two drug pairs, Simvastatin-Itraconazole and fluoxetine-selegiline, were correctly identified for a potential interaction by all of the DDI checkers. All but one website correctly identified the Warfarin-Gemfibrozil drug interaction. Another website failed to identify the Warfarin-Levothyroxine drug pair, but correctly identified all other drug interactions. 20 websites had identical results likely indicating a common DDI assessment engine in use.

Discussion

The study findings indicate that the many of DDI Checkers operate similarly or even identically as would be expected for a series of well-established DDI medications. Of the 44 websites, 20 had identical scores with an Information Capacity score of 13, Patient Usability Score of 2, and Flesch-Kincaid Grade Level of 12.4. The results also show that the majority of these websites may not be optimally patient-oriented with a low average Information Capacity Score and an average Flesch-Kincaid grading level of 11.2. The optimal Flesch-Kincaid reading score for patient oriented content would be lower with grade levels of 6-8 to be easily readable by most patients from a variety of educational backgrounds. The average Flesch Reading Ease was also lower than expected for ease of use by most readers and indicated that the information given to patients may be difficult to interpret.

The research provides important insights on publically available DDI information systems for well-established DDI combinations. The average Information Capacity Score of 13.36 implies that there are many features that are overlooked by the DDI checkers. Scores not received due to lack of a severity rating was the primary reason for the low scoring in Information Capacity. Other features that contributed to a decreased Information Capacity scores included the absence of the Selegiline-Phenelzine drug interaction, lack of presence for drug to food interactions, absence of drug-alcohol interactions, and absence of the therapeutic duplication data. Reasons for the lack of drug-food interaction and drug-alcohol interaction may have been due the fact that the websites focused on strictly drug-drug interactions or may have lacked the content in their database.

Another broader concern was the variability in severity ratings among the websites which provided severity data. The interactions used in the assessment are well known and clinically significant. Although the vast majority of sites indicated the presence of an interaction, the lack of severity data and lack of consistent severity data is potentially problematic. If a patient were to put in a medication combination which has a low risk of adverse clinical effects and gets no cues on severity and at the same time inputs one or more of the combinations included in this study, they may get the message that the low-risk combination is the same risk as the high risk combination. This has the potential to provide inappropriate messaging depending on how the patient perceives and internalizes the lack of risk severity. It is also easy to see a scenario where a patient may have a complicated regimen with multiple interactions and asks their physician or pharmacist about the interactions and gets reassurance on the first couple of interactions and then fails to ask or appreciate the risk for a high risk combination further down the list. Among the medications used in the study, there was also an unexpectedly high variation in severity rankings when it was provided. It would be expected that the severity data would be more homogenous, but in figure one the range went the full range of minor to contraindicated which is concerning from a patient safety standpoint and none of the pairs had full agreement on severity when it was provided. In addition, some of the interactions were not noted as DDIs on some sites.

The patient usability and reading levels could be addressed by insuring the content has multiple modes of risk communication with percentage data, risk symbols and use of color coding or other pictographic elements to convey potential risk when present. For the readability and reading ease, the DDI information system content could use more simplified explanations so as not to overwhelm the drug consumer with the information content and have less use of medical jargon. The high grade level to the content may have been due to the reuse of risk information developed primarily for use by health professionals.

Limitations to the study include a lack of prior studies in DDI information capability to use for scoring and assessment. Without a well-recognized grading criterion for patient oriented DDI information systems, generating one would require a consensus among professionals as to how important each grading factor was in evaluating these information systems. Future work to validate the scoring approach is being planned to assess scoring validity. Another limitation included a small sample of drug pairs as well as limited number of drug classes which were
studied which may have affected the study outcomes. There are many more clinically significant drug interactions that were not included in this study and further research could provide additional insight with an evaluation of those drug combinations. Ideally more drug combinations would have complemented the research, but with the time and effort needed to complete the thousands of potential drug interactions it would require a large labor effort. Furthermore, additional DDI combinations are likely to have diminishing returns. Also of note, many of the websites generated identical results and it would be expected that the pattern would continue with testing of additional drug pairs.

An additional limitation was the lack of actual patient feedback on the use of the systems. However, without systematically screening and assessing the quality of the information provided, putting patients with their actual drug regimens was deemed potentially problematic since counter-detailing may have been required based on clinical circumstances and the patient guidance provided by the sites. Assessing patient initiated mock drug profiles may be an alternative approach to get pertinent patient data on website usability.

Conclusion

The results of the research indicate that the content of these websites is similar but a large number of sites lack severity data, advanced drug profile management, and therapeutic class assessment. In addition, there is a broad problem of limited patient readability and limited patient oriented risk communication features. Based on the study results, further research and website development work is needed to improve patient oriented DDI information systems.

Possible approaches to improve patient oriented DDI checking sites could be the incorporation of a standardized severity grading scale to avoid potential confusion for the drug consumers on DDI risk. Improvement of patient oriented DDI information systems should also focus on simplifying drug interaction information provision to consumers with patient oriented content and inclusion of advance drug information management features.

Abstract

The financial incentives for data science applications leading to improved health outcomes, such as DSRIP (bit.ly/dsrip), are well-aligned with the broad adoption of Open Data by State and Federal agencies. This creates entirely novel opportunities for analytical applications that make exclusive use of the pervasive Web Computing platform. The framework described here explores this new avenue to contextualize Health data in a manner that relies exclusively on the native JavaScript interpreter and data processing resources of the ubiquitous Web Browser. The OpenHealth platform is made publicly available, and is publicly hosted with version control and open source, at https://github.com/mathbiol/openHealth. The different data/analytics workflow architectures explored are accompanied with live applications ranging from DSRIP, such as Hospital Inpatient Prevention Quality Indicators at http://bit.ly/pqiSuffolk, to The Cancer Genome Atlas (TCGA) as illustrated by http://bit.ly/tcgascopeGBM.

Introduction

Technological and policy trends are reshaping the development and deployment of Biomedical Informatics applications. The increasingly data-intensive, patient-facing nature of modern Medical Systems are translating well established architectural recommendations, such as the decoupling between the data layer and presentation layer, into specific requirements. Furthermore, the ongoing evolution of the Web into a global data space (Heath 2011) is now a ubiquitous Big Data reality, with the Web Platform (Web Platform 2013) serving as its unifying computational environment.

As a matter of policy, public data held by government agencies in the US and many other countries must be available as Open Data (White House 2013). The technical requirements for Open Data play a foundational role in Web Technologies, defining a degree of openness along a 5 point system (Berners-Lee 2011), which ranges from being on the web (1 point) to using a linked Resource Description Framework (RDF, 5 points). Most public health data systems maintain a score of at least 3.. This is typically achieved by relying on a nonproprietary format, such as JSON, exposed through an HTTP REST API such as that provided by Socrata’s SODA data services (Socrata 2014). The availability of a wealth of health data resources satisfying this level of interoperability can be readily verified by pointing a web browser to State and Federal data resources such as health.data.ny.gov, data.medicare.gov, data.healthcare.gov, or data.cms.gov.

This report explores the feasibility of OpenHealth analytical applications that are entirely free from server-side presentation resources. The motivation for this approach derives from the
unparalleled scalability promised by “beyond the data deluge” analytical solutions based on code distribution (Bell 2009). This pursuit is also informed by a number of previous results showing that client-side code distribution is no longer bound by significant algorithmic or performance limitations. Regarding the latter, browser hosted computing was shown to scale well into the realms of HPC (Wilkinson 2014). Similarly, even specialized operations, such as image (Almeida 2012a) and sequence analysis (Almeida 2012b), have, for some time, been efficiently supported by the computational engines of the Web Platform. Nevertheless, it was also abundantly clear from the onset of the study that new capabilities were needed for functionalities conventionally hosted server-side such as data caching and normalization. A third challenge to the OpenHealth route was devising an approach to the user interface assembly that would allow researchers to present prototype analytical applications to domain users with minimal overhead.

Methods

Computational application - The OpenHealth platform was developed entirely in client-side JavaScript, which is made publicly available, and is publicly hosted, with version control and open source, at https://github.com/mathbiol/openHealth. The versioned hosting feature is achieved by versioned code development in GitHub’s gh-pages branch. The architecture of the OpenHealth platform is detailed in the Results section, and includes reliance on the native NoSQL data management and storage resources of the Web Browser - IndexedDB (http://www.w3.org/TR/IndexedDB). Code development, including the use of IndexedDB, was pursed with strict adherence to W3C standards recommendations. In principle, this should render OpenHealth cross-browser, but this behavior was only tested for Google’s Chrome and Mozilla’s Firefox browsers, albeit on multiple platforms: desktop, tablet and cell phones running multiple operating systems: Mac OS, Windows, Android, and Chrome-OS.

External data and libraries - The illustrative applications make use of specialized libraries for visualization, d3.js (https://github.com/mbostock/d3), and dimensional charting (https://github.com/dc-js/dc.js). Data caching was mediated through Mozilla’s open source localForage.js library (https://github.com/mozilla/localForage). These libraries were chosen, in part, because of OpenHealth’s emphasis on public versioned hosting of open source code. Similarly, all data used in the applications described in this report are available in the public domain from a variety of State and Federal agencies, primarily hosted by health.data.ny.gov and data.medicare.gov for case study examples 1-3. In all three cases, data retrieval is performed by demand of the analysis, using the Socrata JSON formatted open data services API (http://www.socrata.com/products/open-data-api) of those Open Data resources. The data normalization case study 4, which uses data from The Cancer Genome Atlas (Figure 5) illustrates a solution for patient-derived data resources made public without the complement of a data service API, or even of a Cross-Origin Resource Sharing (CORS) enabled web serving. The solution found, described in Results, is the basis for a number of recommendations in the Discussion. The TCGA data used is nevertheless in the public domain (no restricted access TCGA data sets were used), hosted by The National Cancer Institute of The National Institutes

Results
The main goal of this project was to develop a distributable platform for data-intensive computation of OpenHealth Data entirely as a client side Web Application. This design overcomes the need for server-side components and maximizes scalability through code distribution (Bell 2009). Open Government mandates and NIH dissemination requirements have engendered a wealth of reliable, high availability, Big Data web services. These web services and their patient-resolved clinical and biomolecular data are central to the interactive systems described, which illustrate the use of the OpenHealth platform (OH).

Architecture

Figure 1 - Simplification of the conventional server-side data management and normalization architecture (A) by relocating that functionality (B) to the OpenHealth Platform (OH) assembled within the browser (dynamically loaded as JavaScript libraries), using native, W3C standardized, data management resources such as NoSQL IndexedDB (http://www.w3.org/TR/IndexedDB). It is critical to note that in (B), all data and computation is performed by either the data providers or by the domain consumers, not by dedicated Biomedical Informatics computation infrastructure - which is no longer needed. In other words, all that the Biomedical Informatics application layer does is provide the JS code, distributed directly to the Web Browser hosted OH component, by the standard script tag injection mechanism.

Illustrative applications with <OpenHealth>?<analysis> URL composition
The OpenHealth platform’s data management and normalization functionalities are best visualized through illustrative examples. These illustrations will address four boundary scenarios: 1) Graphic interaction with a large data resource containing population-level data; 2) traversal of a large collection of individual patient data; 3) Cross-tabulation of multiple sources;
and 4) normalization of patient-derived biomedical data available in the public domain as raw data files. In each of these examples, the same code migration URL composition pattern is invoked. OpenHealth’s core library is dereferenced with the analytical code pulled in as an additional search parameter. For example, the interactive representation in Figure 2 can be produced from http://mathbiol.github.io/openHealth/?jobs/pqiSuffolk.js.

1) Graphic interaction with a large data resource containing population level data

Figure 2 - Pure client-side assembly of an interactive tool for Hospital Inpatient Prevention Quality Indicators (PQI) for Suffolk County, Long Island, NY: bit.ly/pqiSuffolk. The analysis begins with OH retrieving the data for each of the relevant 107 zip codes (out of 111474 described in the reference health.data.ny.gov/resource/5q8c-d6xq source for the state of NY), and caching them in the native NoSQL browser resource, IndexedDB (see Methods). Like other native data resources, such as localStorage and WebSQL, IndexedDB will persist between sessions for the domain name. As a consequence, subsequent accesses to this interactive Web Application will not exhibit the same initial waiting period for data retrieval.

To illustrate the point that <openHealth>??data analysis</openHealth> is just a generative pattern, and that the analysis code can be dereferenced from both relative or absolute URLs, it is useful to note
that the same result captured by the snapshot in figure 2 could be produced by http://mathbiol.github.io/openHealth/?https://rawgithub.com/SBU-BMI/openHealth/33a1b22d0e0f7fd786bfe2ebbf024ac55523262/jobs/pqiSuffolk.js. This formulation highlights the criticality of the versioned hosting feature of OH; the analysis URL points to a specific version, hosted in a different domain. That is, for the preventable disease interactive display coded by version UID 33a1b22d0e0f7fd786bfe2ebbf024ac55523262. The URL composition is convenient to illustrate this report, but a more useful approach may seek to engage the code migration functionality programmatically, as discussed later in this report.

2) traversal of a large collection of individual patient data

Figure 3 – Tabulation tool dereferenceable by shortcut bit.ly/sparcs2012. This example illustrates the logistics of traversing over 2.5 million de-identified hospital inpatient discharges in the state of NY in 2012 (Open Data resource health.data.ny.gov/resource/u4ud-w55t). The command line inset is a snapshot of the browser native tools, showing the values of 36 parameters for one of the 168,044 records found for Suffolk county. Note that first use of this interactive application will require pre-processing times of a few minutes, depending on the machine, but subsequent uses have OH shorten data retrieval to under half a minute, even in a moderately resourced mobile devices.
3) Cross-tabulation of care providers

Figure 4 - Example of an interactive application that crosses two Medicare databases for an arbitrary provider identifier and the corresponding hospital affiliations. Loading times should be nearly instantaneous on any device.

4) Normalization of patient-derived biomedical data made public as raw text files. The example application in Figure 5 tests the limits of what can be accomplished using the proposed approach when the patient-derived data is exposed without any specific provisions for web-based processing (see Discussion). This application retrieves two raw text files from https://tcga-data.nci.nih.gov/tcgafiles/ftp_auth/distro_fupusers/anonymous/tumor/gbm/bcr/biotab/clin/, one describing the clinical data for 592 TCGA patients diagnosed with Glioblastoma Multiforme, nationwidechildrens.org_clinical_patient_gbm.txt, the other describing 1,284 pathology slide images obtained from the corresponding tumor samples, nationwidechildrens.org_biospecimen_slide_gbm.txt. While it may not lead to a noticeable delay in data retrieval and normalization, the inspection of the application code, migrated from github.com/mathbiol/openHealth/blob/gh-pages/jobs/tcgascopeGBM.js, will reveal the mediation of a cloud hosted proxy application, bit.ly/getTCGAxt, that pass the text content across TCGA data hosting domain restrictions (see Discussion).

Discussion

The interactive applications and supporting data processing configuration of the OpenHealth platform is proposed to be a good fit for patient-centric, outcomes-driven health delivery programs such as Medicaid’s Delivery System Reform Incentive Payment (DSRIP, bit.ly/dsrip) and the new Patient-Centered Outcomes Research Institute (PCORI). However, the domain
facing nature of modern Information and Communication Technologies (Almeida 2014) is, of course, not a reaction to these systems—quite the opposite. Healthcare is a latecomer to both the commoditized consumer-facing ICT (Mandl 2012) and the operational improvements facilitated using Big Data (Murdoch 2013, Manyika 2011). Therefore, it is reasonable to anticipate that the growing wealth of patient-resolved health data resources delivered by Open Government mandates, as articulated by the US Department of Health and Human Services (HHS 2015), will fundamentally change not only Health Information Systems, but the research and understanding of disease (Roth 2015). What data services and application development architectures will prove more effective in meeting those goals is the broader question that the OpenHealth platform described here explores.

Figure 5 - Snapshot of interactive application assembled from TCGA raw text files describing TCGA patients diagnosed with Glioblastoma Multiforme, and the pathology slide images obtained from the corresponding biopsies (see text for details). The cartesian plot on the right projects, interactively, the position of each patient by age and survival (days to death), while tracking the Karnofsky score (color) and images (diameter). The effect of histopathology and demographic features can be assessed visually through interaction with the corresponding bar charts.

The interactive applications in figures 2-4 provide evidence that OH’s server-less architecture, described in Figure 1B, is computationally more efficient, it is far easier to disseminate, distributing analysis that are therefore easier to reproduce. Although the applications in the Results section were assembled by a URL composition pattern, <openHealth>?<data
analysis>, the core OH library can be loaded programatically by script tag loading as in `<script src="https://mathbiol.github.io/openHealth/openHealth.js"></script>` or, for example, using jQuery, `$.getScript("https://mathbiol.github.io/openHealth/openHealth.js").` This is explained in detail in the project’s code development page at https://github.com/mathbiol/openHealth.

The interactive TCGA Glioblastoma (GBM) application described in figure 5, however, explores a more convoluted scenario, wherein the data is served to the public domain, but no API is available and cross-domain calling (CORS) is disabled. These obstacles have been noted by several reports over a number of years, but persist on many open repositories of public data. To overcome those barriers to interoperability with interactive web applications, we were compelled to develop a minimal proxy (server-side) mediator. To avoid a relapse to the troubled dependency on server-side resources (Fig 1A), we developed that TCGA proxy component as a Google Cloud hosted service, which can be inspected at bit.ly/getTCGAtxt. The TCGA GBM application was implemented to augment a web-based virtual microscope deployment, which hosts TCGA microscopy image data and image segmentation results. The application allows users to visualize various clinical attributes and select a subset of cases based on these attributes. Users can then interactively view these select cases using the virtual microscope platform. The need for the proxy component could have been entirely removed if the TCGA data web server included an open domain header (CORS), as noted elsewhere, namely (Robbins 2013) section 4.5 “Summary of technical recommendations for biomedical big data hosting”. On a more positive note, the normalization of the TCGA file contents did not itself present a major obstacle, as can be verified by noting the short loading/parsing times of bit.ly/tcgascpeGBM (Fig 5), and by following the cBio links (Cerami 2012) to those Web Applications.

**Conclusion**

OpenHealth is an in-browser JavaScript platform developed to mediate the management and normalization of Open Data in the Health Sciences domain in a manner that is scalable, secure and reproducible. Data pre-processing functionalities are conventionally associated with dedicated server-side resources. OpenHealth redirects that support to the native data resources of the modern Web Browser, which is now equipped with a computationally efficient JS interpreter, secured within a sandbox that isolates the execution of code migration from unauthorized access to additional local resources. This approach was found to be particularly effective for the development of interactive applications, and for the dissemination of reproducible analytical procedures. Mounting adoption of Open Government and Open Data mandates in Health Care suggests a key role for this architecture in measuring health outcomes and personalizing care delivery.

**Abstract**

A major challenge in advancing scientific discoveries using data-driven clinical research is the fragmentation of relevant data among multiple information systems. This fragmentation requires significant data-engineering work before correlations can be found among data attributes in multiple systems. In this paper, we focus on integrating information on breast cancer care, and present a novel computational approach to identify correlations between administered drugs captured in an electronic medical records and biological factors obtained from a tumor registry through rapid data aggregation and analysis. We use an associative memory (AM) model to encode all existing associations among the data attributes from both systems in a high-dimensional vector space. The AM model stores highly associated data items in neighboring memory locations to enable efficient querying operations. The results of applying AM to a set of integrated data on tumor markers and drug administrations discovered anomalies between clinical recommendations and derived associations.

**Keywords**

Associative memory, breast cancer treatment, electronic medical record, tumor registry, data integration, correlation

**Introduction**

While critical data on tumor pathology, genomic biomarkers, patient demographics, and clinical treatments are often gathered in different resources, investigators need all of these results to be brought together for comparative effectiveness, population research and translational science. For example, data linkage between the SEER cancer registry and the Medicare claims database has been valuable in discovering population-based patterns in cancer screening and treatment outcomes that would not be possible otherwise⁴. As part of the Oncoshare project⁵, a collaborative multi-institutional study of patterns, predictors, and outcomes of breast cancer care, data integration between local and state cancer registries with electronic health records revealed the limitations of relying on any single source for research. Before linking data among different systems into Oncoshare, the separate data sources revealed varying rates of cancer-specific diagnostic tests and treatments. For example, the rate of mastectomy in one hospital’s registry was 41% but the facility’s billing record only indicated that about 22% of patients received such surgical intervention⁶. After manual verification of the missing data, the rate of mastectomy across data sources was found to be 43%. In addition, linking revealed data patterns that were implausible, such as patients whose treatment dates from the EMR occurred a year before receiving cancer diagnosis in the registry.

Many academic medical centers are undertaking this data integration effort by creating data warehouses that incorporate research-related data from a variety of systems. Such an approach requires considerable planning and programming efforts that may require a year or more before the data warehouse is usable for research⁷. While data warehousing permits robust and rapid querying over uniformly represented data, this solution has a number of drawbacks for researchers as end users. Data warehouses typically do not incorporate all of the data in source systems, do not allow for multiple relationships to be maintained among source data, do not manage provenance of the data, and do not monitor changes in the schema or data quality in source data.

Several informatics groups have created new methods to tackle various aspects of this problem. For example, the Electronic Medical Records and Genomics (eMERGE) Network method aims to link samples and results collected from genetic studies to electronic medical records data to allow for high throughput biomarker studies⁸. The widely used Informatics for Integrating Biology and the Bedside (i2b2) data repository method allows for the merger of multiple sources of genetic, phenotypic, and other types of data into a single integrated schema that supports queries across data sources⁹. This prior work on data linkage and data warehousing methods provides data integration at the data or schema level, but not at the systems level. That is, these methods do not model or automatically adapt to
changes in the information systems that provide data. Consumers of integrated data may, as a result, not be aware of which systems provide data and when new systems have emerged or existing ones are altered.

In this paper, we explore the use of a novel data modeling approach, called *associative memory* (AM), which permits the rapid integration and correlation of data from multiple data sources\(^7\). Our analysis technique comprises an AM model\(^7\) that allows for a form of cognitive computing to mimic the human capabilities of processing, encoding, consolidating, and retrieving information from a constant influx of data streams captured via the sensory organs. We choose this model as it has the potential to address the volume, velocity, veracity, and variety (the four V’s of big data) challenges of data source agnostic aggregation and analysis. We apply the AM approach to rapidly integrate patient data collected from tumor registry and electronic health records, and conveniently identify the correlations between tumor markers, patient factors, and selection of administered drugs. While some of the identified correlations follow expected clinical patterns, others point to anomalies between clinical guidelines and drug administrations, indicating the need for further studies on the quality of drug administration recording as well as patient and physician adherence to the recommended guidelines. We also compare the simplicity of this approach against the more traditional effort needed with generating reports using SQL.

**Methods**

**Design and experimental setting:** Our breast cancer data sets come from two sources at Dartmouth–Hitchcock Medical Center (DHMC). The first source is a patient tumor registry and the second source is an electronic medical record (EMR) database, which is from the Epic vendor that was installed at DHMC on April 2, 2011. The current tumor registry has existed in its current form for the past decade. To evaluate our proposed AM approach, we obtained IRB approval to extract patient data from both the systems on November 1, 2014. The EMR data consisted of encounter data that recorded diagnostic and treatment information, including medication administration records. The tumor registry data consisted of stage (pathological, clinical, and combined) and grade information, along with tumor markers, specifically progesterone receptor (PR), estrogen receptor (ER), and HER2/neu.

Using the diagnostic date stored in the institutional tumor registry, we identified female breast cancer patients who had invasive breast cancer (Stage I-IV) after April 2, 2011, and we cross-linked these cases to their data within the EMR. Since we required treatment data and treatment is normally completed within a year, we limited the date of diagnosis to be one year before November 1, 2014. The data sets consist of 928 patients and 50,490 encounter records collected over the specified period. For automated de-identification of patient data, we identify each patient solely by a digital fingerprint that is created by a one-hash algorithm\(^4\). Using the digital fingerprint, we define a fixed, random temporal offset between plus or minus 30 days that is added to all the time stamps for a patient, effectively altering the true time of occurrence but maintaining the relative temporal distance between the events.

![Figure 1: Conceptual illustration of associative memory system showing data aggregation and analysis techniques](image-url)
While various AM models have been proposed, we adapt a specific implementation described in a 2011 patent that is efficient, easy-to-use, intuitive, and scalable. By replacing the data items that are conventionally stored in tables or tuples with elementary “atoms” of information residing in a common n-dimensional (n ~ 1 billion) vector space of contextual associations among the data attributes, this AM model (Figure 1) provides a unified and compact representation for any data type, dynamic or stationary, structured or unstructured, of arbitrary size and granularity.

The atomic pieces of information are represented as byte arrays of arbitrary sizes where the maximum size limit is enforced by the operating system constraints. The associations among the data items are naturally formed based on all the attributes such as the names, counts, hierarchical relationships, and qualitative and quantitative properties of the items. The quantitative properties are categorical strings, discrete integers, or continuous-valued floating point numbers, names and qualitative properties are represented as strings, and hierarchical relations are denoted as binary integers linking pairwise items. Each attribute type, other than hierarchical relations, then forms a dimension of the associative vector space (AVS) in which all the data items are organized.

Naturally, the data attributes vary widely among items representing fundamentally different entities such as chemotherapy protocols and surgical procedures, but are identical, albeit with different values, for the same entity. Various instances of identical entities lie in the same sub-spaces of the AVS, whereas instances of different entities occupy different sub-spaces of the common AVS. The sub-spaces for the different entities may overlap, indicating the presence of common attributes among them. Multiple occurrences of the same entity instance are represented as the same atomic piece of information with the provision to add more attributes, and, thereby, increase the dimensionality of the occupying sub-space. All the instances of a particular entity or similar entities are strongly connected to each other, thereby forming a natural cluster using a simple heuristic k-means method. This method

Figure 2: Simple user interface to define and run queries on breast cancer patient associative memory model
employs a hybrid Euclidean (for real-valued attributes) - Hamming (for string attributes) distance function as the similarity metric or the connection weights between the data items. Instances belonging to different clusters may also have some connections, but those are much sparser with lower weights. These connections are bi-directional and dynamic, thereby enabling the additions of new associations as more data is ingested.

While commonly contextualized (clustered) data entities are co-located in the organizational space, a virtual pointer-like token, called the relationship construct, provides the means to connect anything in the AVS to anything else. Each token uniquely identifies a particular atom of information, is the virtual location of the item in the AVS, and is the logical address of where the item exists on the physical storage medium. This capability ameliorates the requirement for physical co-location to articulate sub-spaces and instead uses associative nearness (shortest connecting path length) or dimensional proximity (number of overlapping sub-space dimensions) to enable endless clustering possibilities of data entities in an unlimited number of sub-spaces. This multi-faceted holographic-like framework allows for viewing of data from virtually any perspective without the need for additional processing. Furthermore, one no longer needs to search for identifying any form of associations among the data items as all such associations are maintained as tokens, co-incident with the related data items. Thus, the associations are obtained by merely referencing the items of interest and using the co-incident tokens to directly index the referenced items in the storage medium. This novelty allows for real-time correlation analysis as long as the data attributes are defined by the user. Figure 2 shows the user interface for interacting with and querying the data.

We use this AM system for aggregating and analyzing the breast cancer tumor registry and EMR data sets. Cancer patient factors, namely, comorbidities and hormone-receptor status, together with diagnosis and treatment information like cancer stage, chemotherapy protocol, and secondary therapeutic drugs constitute the set of attributes. Once the AM model is generated, automated queries are run using a C# API provided by the implementation system of our choice to retrieve the associations between the drugs of interest (both chemotherapy and secondary treatment drugs) and patient factors.

**Outcome measurement:** In this paper, we investigate a specific clinical question of identifying the correlations between treatment drugs and the stage of breast cancer and hormone-receptor status of patients. Our output metric is always the number of supporting evidences, i.e., the count of patients with identical factors who are administered a particular drug. Simple graphical displays such as scatter plots are generated using Python version 2.7 to visualize the presence and strength of the correlations. Comparisons are made with SQL to highlight the usefulness of the AM system in identifying the correlations with less implementation effort and in identical level of accuracy.

Two-sample t-tests with unequal sample variances (Welch’s test) are run using R version 3.1.3 to test the statistical significance of the correlations, where the first sample consists of the proportion of patients of a particular type (e.g., specific hormone-receptor status) who are treated with a fixed set of chemotherapy or both chemotherapy and secondary drugs, and the second sample comprises the proportion of patients who are receiving the same set of drugs but are not of the first type. Patients of unknown types are excluded while computing the proportions. The null hypothesis that the two samples means are equal is rejected if the corresponding p value is less than 0.05, thereby establishing a correlation between the patient type and administered drugs with 95% significance level.

**Results**

We obtained the results on an Intel Core i7-4500U processor with 8 GB RAM and 1.8 GHz processor speed in 64-bit Windows 8 operating environment. Using the AM system, it took 6.065 minutes to generate all the patient counts as functions of breast cancer stage and hormone-receptor status, and 0.781 minutes to obtain all the patient counts as functions of hormone-receptor status and specific chemotherapy and hormone-targeted drugs. While SQL queries took about the same time to execute, they required a lot more programming effort, as shown by the snippet of required SQL query in Figure 3. No differences in the retrieved patient counts were observed between the two approaches.
public CancerDB(String host, String user, String password) {
    frm = new IAMFramework();
    // login
    sessionId = (new Random()).nextInt(1, 1 << 16);
    ActionFlags f = new ActionFlags();
    f.SessionID = sessionId;
    frm.LOGIN(host, user, password, "ManagerT", f);
    // get model
    f.GET.OpQualifiers.OpApplyVia =
        ApplyVia.enApplyViaDictionary;
    GenericList modelList = frm.GET("CancerData201504",
        null, null, new ReturnAs(), f);
    model = frm.ExtractPersistable(modelList)[0];
}

public Core.KeyValuePair getConceptByConceptName(String conceptName) {
    ActionFlags f = new ActionFlags();
    f.SessionID = sessionId;
    f.GET.OpQualifiers.OpApplyVia =
        ApplyVia.enApplyViaDictionary;
    return frm.GET(model, conceptName, null, ",", f)[0][0];
}

Figure 3: Screenshots of code using (a) associative memory system to query any combination of patient, tumor, and drug factors, and (b) SQL to specifically query patient counts for drugs based on hormone-receptor status

Figure 4: Variations in the number of breast cancer patients who various stages of invasive breast cancer and hormone-receptor status displayed using a scatterplot with circle size proportional to the patient count.

Using our AM model, we first examined the relationship between breast cancer stage and patient hormone receptor status. Figure 4 shows the results of variations in the number of patients who have different stages of invasive breast
cancer and their hormone-receptor status using a scatterplot with circle size proportional to the patient count. The results indicate a predominance of patients with ER+/PR+ and triple positive (ER+/PR+/HER2neu+) status along with early stage patients (1A, 2B, and 2C) within the extracted cohort. Similar predominance has been observed in other breast cancer patient cohorts.

Figure 5: Variations in the number of breast cancer patients receiving different chemotherapy drugs based on hormone-receptor status displayed using a scatterplot with circle size proportional to the patient count.

We next examined the correlations derived from the AM model between hormone-receptor status and choice of chemotherapy agent that was administered, which is shown in Figure 5 as a scatter plot. The figure indicates a predominance of the use of cyclophosphamide, doxorubicin, and paclitaxel, which are agents associated with recently recommended chemotherapy protocols for patients who have stages I-III breast cancer.

We then examined the relationship between hormone-receptor status and hormone-targeted treatments in the form of trastuzumab, pertuzumab, and methotrexate. Clinically, according to national guidelines such as those published by the National Comprehensive Cancer Network, we expect that the hormone-targeted treatments would be only used in patients who are HER2/neu positive. In our analyses using the AM model, we, however, found that a small subset of patients who were HER2/neu negative (categorized as triple negative or ER, PR positive) had also received hormone-targeted treatments, as shown in Figure 6.

We also computed two-sample t tests to validate the correlations between chemotherapy and hormone-targeted agents and hormone-receptor status in breast cancer patients. The results are shown in Table 1. Statistically significant differences between patients who were ER+, PR+, and ER-PR+ versus patients who had other hormone statuses in the receipt of both chemotherapy and a hormone-targeted agent were observed, which is clinically expected. Interestingly though, patients who were HER2/neu positive and ER, PR negative were not different in their receipt of chemotherapy and hormone treatment. Furthermore, HER2/neu positive patients with some combination of ER or PR positive status actually received significantly less chemotherapy and hormone-targeted agents than the others. Both of these findings contradict clinically expected patterns.
Table 1: \( p \) values corresponding to two-sample \( t \) tests to validate the correlations between drug treatment and hormone-receptor status in breast cancer patients with statistically significant correlations (\( p < 0.05 \)) highlighted in bold; all the tests are one-sided with * and ** denoting greater and lower means of the first sample, respectively.

Discussion

The integration of heterogeneous data from multiple source systems is a time-consuming process and a rate-limiting step to rapid exploration of data, whether such efforts occur through standard data warehousing approaches or by data integration platforms, such as i2b2. In our work, we use a novel method for ingesting data from multiple sources into an associative memory (AM) model that is designed to mimic the ways humans store information through content-addressable memory and make rapid associations between the concepts. We have taken a commercially available database method for associative memory and implemented a programmatic interface that allows us to query the naturally occurring clusters generated by the model. In this paper, we have shown the feasibility of the AM approach to organize heterogeneous data efficiently based on attributes, and rapidly generate associations among the data attributes. Although the run time of corresponding SQL queries is similar to the AM model, the SQL query requires more technical expertise to formulate and thus more data engineering effort.
Using the approach, we interrogated the AM system to find associations between breast cancer stage, hormone-receptor status, and drug administration. The results of these analyses show expected clinical relationships between tumor factors and therapy choice. However, we also found a few anomalous patterns between hormone-receptor status and the use of hormone-targeted therapy. These patterns may be due to several factors including incorrect pathological identification or administration records, and thus require us to validate the information using other sources of data. Of note, however, is that our statistical validation step did not provide us the expected pattern of distinguishing hormone-receptor status between those who received chemotherapy alone and those who received those agents in conjunction with hormone-targeted therapy.

The AM approach we have chosen allows us to make rapid exploration of other patterns within the data and to easily scale the method to much larger data sets. For our future work, we will import data into the AM model from other types of cancers that are within the tumor registry, and we will begin exploring expected and unexpected clinical patterns with clinical feedback. We recognize that reviewing such highly multi-dimensional relationships in the data will require visualization approaches, and we are developing 3D methods using the OpenGL standard to enable such exploration directly by clinicians.

Abstract

Computerized wearable devices such as smart watches will become valuable nursing tools. This paper describes a smart-watch system developed in close collaboration with a team of nurses working in a Swedish ICU. The smart-watch system provides real-time vital-sign monitoring, threshold alarms, and to-do reminders. Additionally, a Kanban board, visualized on a multitouch screen provides an overview of completed and upcoming tasks. We describe an approach to implement automated checklist systems with smart watches and discuss aspects of importance when implementing such memory and attention support. The paper is finalized with an in-development formative evaluation of the system.

Introduction

The nurse watch has been a valued nursing tool since the early 20th century. Being predominantly employed in the United Kingdom, besides offering a time reference, it provides the nurse with a quick method of taking the 60-second pulse rate of patients using a pulse scale. Due to hygiene requirements, the watch is carried up side down on a chain (fob) and attached to the uniform for fast reference. The introduction of wearable technology such as wireless computerized smart watches from manufacturers such as Apple, Motorola and Samsung provide designers with a new set of possibilities to support medical professionals. For example, these developments make it possible to design and develop specialized nurse applications that run on smart watches. However, very few smart-watch designs for nursing have been presented.

Using checklists and reminders in clinical care have been shown to provide significant improvements in patient outcome and patient safety¹. Checklists can support standardized nursing care, aid workflow, and act as reminders of work-to-do²,³,⁴. Moreover, studies show that appropriately-designed workplace arrangements and applications can offload cognitive demanding tasks and allow the clinician to focus on the important activities. Some studies, however, report that reminders have less significance to clinical outcome and routines⁵. Nevertheless, studies have identified compliance problems with both paper-based and computerized checklists⁶ such as neglecting to use a checklist or not acting on a computerized reminder.

We have developed a smart-watch application and an adjunct Kanban task board to be used by ICU nurses during day and night shifts. The basis for the design was to approach a set of issues related to the use of checklists and reminders at a Swedish ICU. The goal was to improve workflow and patient awareness at the ICU. To direct the design, we applied the theoretical framework of Distributed Cognition⁸,⁹ to understand underlying aspects of checklists and reminders that are of importance when designing memory and attention support. This paper is organized as follows: First, we review research on checklists and their usefulness. Second, we discuss theoretical aspects of checklist and reminders based on the theory of Distributed Cognition. Third, the method section describes MODUS, the framework in which we have developed our approach as well as discussing how we elicited the requirements for the system. The remainder of the paper presents the smart watch app, its formative evaluation and discusses the pros and cons of the overall approach.

Background

Nurses have many responsibilities during day and night shifts. Numerous studies have demonstrated how reminders and alerts can be helpful in focusing the nurses’ attention on specific tasks. Reminders and alarms can be seen as decision-support tools¹⁰ designed to improve patient outcomes, reduce medical errors, and increase compliance with standards of care. A variety of formats have been devised such as paper-based and computerized reminders. Rind and colleagues showed that computer-based alerts and related changes in clinical practice had a respectable effect on preventing renal impairment and function of patients¹¹. Oniki and colleagues studied computer-generated reminders on charting omissions and they could show a clear decrease in charting deficiencies¹². The mid-day reminders
appeared to reduce deficiencies in the nurses’ charting and the reminders were helpful in focusing the nurses’ attention. Thongprayoon and colleagues showed that an electronic checklist reduced significantly provider workload and task errors\(^1\). This study also suggested that electronic checklists are feasible in the ICU setting. Before we describe our approach to the design of reminders using smart watches and Kanban boards, let us discuss some theoretical aspects of checklists and reminders.

**Distributed cognition of checklists and reminders**

According to Norman, are there numerous cognitive aspects to the checklist\(^4\). First, without the list one needs to remember all tasks. On the other hand, when having a list, we need to remember little since the planning and remembering process was done in advance. At the time we enact the actions of the list, we do not need to repeat the planning and remembering process and this offloads cognition during execution. However, the use of a list also introduces new tasks: remembering to consult the list and reading and interpreting the tasks on the list. Naturally, having the physical reminder *visible and upfront* is important when relying on them for remembering tasks. According to Hutchins is this situation an example of *Distributed Cognition*; the computational task of remembering is distributed across time and across internal and external representations\(^8,9\) which comprise a robust memory system.

**Method**

**Requirements elicitation**

The requirements elicitation and formative evaluation for the Nurse Watch were done iteratively and dynamically with a team of nurses using a Scrum methodology\(^15\). This comprised software development, user demo, user feedback and subsequent redesign for four one-week sprints. Moreover, the head nurse and team redesigned and integrated a set of paper-based standard checklists and activities that were transformed to an internal XML format in the MODUS system. This transformation also comprised time stamping a set of nursing activities that previously not had been time aligned in the paper version of the checklist.

**System development**

The Nurse Watch was developed and integrated in MODUS, which is a comprehensive visualization environment and database system designed to support medical rounds and remote monitoring of patients in critical care. MODUS collects data from a set of Philips MP70 patient monitors, Braun Space Station Pumps and Maquet Servo-I ventilator systems as well as local picture and laboratory systems. This data is visualized on a motorized 46-inch multitouch tabletop during the round. Additionally, a smartphone application (Android) and Google Glass augmented-reality support remote monitoring of patients’ vital signs. The idea in this project was to add an unobtrusive new user interface to MODUS with a focus on nurses and their needs. In this project, we were able to reuse programming code from our Google Glass implementation and provide subset functionality to the watch. Moreover, we added a Kanban\(^16\) board to our multitouch tabletop to visualize all done and remaining checklist events on a timeline.

**Formative evaluation**

A formative evaluation\(^17\) was performed with seven experienced nurses and nurses’ aides of different ages and IT experience measuring *task completion* and *subjective usability* of the user interface of the Nurse Watch. All subjects had never used a smart watch before. Scenarios and eight test cases were developed covering all possible tasks and user interface components of the clock. The user evaluation was designed as a Wizard of Oz study\(^18\) that entailed simulated alarms and reminders triggered behind the scenes by our test staff. After a very brief introduction to the Nurse Watch the evaluated started and included a think-aloud methodology when the test subjects completed tasks in the scenario. After the initial test session subjects completed the SUS subjective usability questionnaire\(^19\). The session was finalized with a brief interview on the feasibility of the overall approach.

**Figure 1.** The three-tier model of MODUS allows medical equipment such as patient monitors to communicate with the Nurse Watch via the MODUS app.
Result

The current version of the Nurse Watch was developed for the Motorola 360 smart watch\textsuperscript{25} in Java for Android and connected to a set of related systems in a tree-tier model. Figure 1 shows the software architecture. In the present implementation, the Nurse Watch communicates wirelessly via Bluetooth Low Energy to an assistant smart phone also worn by the nurse. A smart phone application manages communication via Wi-Fi with the underlying patient server and databases in MODUS where vital signs data and checklist are stored. Moreover, the smart phone application allows the user to set personal alarm threshold values for the own Nurse Watch. Figure 2 shows the Motorola 360 smart watch running the Nurse Watch application.

\textit{Nurse watch design features}

The Nurse Watch provides two primary features: (1) real-time vital-sign monitoring and (2) reminders of what to do. Navigating the Nurse Watch app is done by ordinary finger sweeps and clicks on the glass surface on the watch. Since this is a very small screen, we were forced to minimize the amount of information shown. Moreover, for patient-safety reasons, we decided to have the patient name and id highly visible on most screens even though this takes up screen surface. The reason for this decision was to decrease the risk of introducing mode errors in terms of assessing the wrong patient based on information from the watch. Figure 3 shows the different user interface panes for vital-sign monitoring and reminders. Let us first discuss the vital sign monitoring part of the Nurse Watch.

The patient pane with vital signs is the primary home screen (see Figure 3, left). This screen is dynamically updated every other second. Scrolling up and down with the finger changes which patient is shown. What is presented is a subset of available patient parameters in the MODUS environment. To create a set of vital signs to be shown on the watch, the clinician chooses these parameters on a digital desk or PC using a drag and drop methodology. This activity allows the parameters to be sent and shown on the smartphone and on the watch. Additionally, the nurse can, using the adjunct phone app, set suitable alarm thresholds for the watch. Figure 4 shows the smartphone app for setting the alarm thresholds.

We implemented a two-level notification scheme in the Nurse Watch: vibration alarms and visual cues. Moreover, we decided to have two types of vibration alarms to notify the clinician on the level of urgency. Two consecutive vibrations denote an urgent alarm and indicate a violation of the threshold of a vital sign. A longer vibration is related to upcoming items on the checklist. Moreover, to clearly indicate what type of vital sign that was out of bounds, the color of the vital sign text changes to red and is flashing to make it stand out.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{The Nurse Watch showing the breath rate of a patient. The additional vital parameters of the patient are automatically shown.}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure3.png}
\caption{The user interface components of the Nurse Watch application. The app provides real-time monitoring of patients’ vital signs and deliver reminders on upcoming task. The nurse can classify a task as done (Swe., Avklarad) or postpone it (Swe., Skjut upp).}
\end{figure}
The Nurse Watch provides notifications on upcoming tasks. These are generated automatically in MODUS based on a time-stamped checklist in XML format that is executed in real time. As mentioned, the system generates a second level notification in terms of a longer vibration in the watch. The nurse can now directly view the task and classify it as completed or postpone it. The status of the task is then updated on the watch and on the Kanban board in terms of visual cues.

The Kanban board

Originally, Kanban boards were introduced in the manufacturing industry to support workflow and to provide an overview of the current work situation. In this project, we combined the traditional checklist with Kanban visualization. The idea is straightforward: every task on a checklist is time-stamped and visualized on a Kanban board. We developed a special pane for this in the MODUS system. The process is initialized when the patient is admitted to the ICU. Then, the head nurse chooses among a standard set of care plans/checklists in MODUS and these are shown on the Kanban board and are sent to the watch. Figure 5 shows a checklist visualized on the Kanban board. In MODUS these tasks time-activated, which triggers the Nurse Watch of the responsible clinician.

Formative evaluation

The formative in-development evaluation revealed some user interface omissions in the first version of the nurse app prototype. The task completion rate for the eight primary tasks were 83 percent and this clearly indicated that there were problems with parts of the user interface. Primarily, two user interface problems were identified; glitches that were resolved in the finalized version of the Nurse Watch. One problem was an inadequate implementation of the alarm screen that required subjects to remember alarm types and patient names during navigation. A better design would have notified the nurse and allowed direct access to the corresponding patient and parameter screen. The second user interface issue was related to insiciencies in how we displayed tasks as being done or not.

The SUS subjective usability scale measures several aspects of the usability of IT systems such as the need for support, training, and complexity of the user interface. The SUS mean score for the first Nurse Watch prototype was 70, which is regarded as OK but not exceptional. Particularly low scored a question on the comfort and security of the prototype. We believe that this result was due to the above discussed user interface issues combined with a very brief introduction to the new technology.

During the interviews the clinicians were generally positive towards the Nurse Watch and the overall approach. The nurses expressed that the user interface of the watch was easy to use and understand. The vital sign monitoring and the related threshold alarms were, by the lion part of the clinicians, seen as the most useful feature of the watch. Checklist reminders were also regarded as a useful function. However, a concern was on the relevancy of the reminder. One nurse stated, for example, that for it to be really useful, it should prompt only key medical tasks, not ordinary standard care task. Moreover, a suggestion was to include functionality to create own reminders that are displayed on the watch during the shift. All nurses expressed concerns regarding hygiene requirements and discussed how it could be worn to comply with these necessities. This discussion also included worries that the watch might reveal information to outsiders. Solutions included screen savers that blacken the display and ways to wear it on a chain (fob) in the pocket. One nurse expressed the need to have a tablet computer with the above-discussed features rather than a smart watch.

Figure 4. Part of the MODUS smart phone app that let the clinician set alarm thresholds for the Nurse Watch.
Discussion

Smart watches can become valuable tools in the healthcare environment. We have exemplified two primary features that can be useful – remote patient monitoring and reminders – that could improve situation awareness and support the memory of medical professionals. On the positive side is the unobtrusiveness of the device that might be its principal advantage in the healthcare environment, where nurses don’t necessarily want to carry bulky tablets or smartphones. On the negative side is screen size, which limits it usefulness as an interactive device. Moreover, energy consumption is still a problem even thought Bluetooth Low Energy is used for communication. Hence, a priority in development should be on applications that make the best out of the energy available on the platform. Related to the above is the reliability of the radio communication. This is still an issue and must be investigated further.

Many healthcare organizations have banned wristwatches because they have been identified being a transfer vector of healthcare associated infections. A possible approach to minimize this risk is to wear it with a chain hanging from the blouse or coat. However, this might impair user interaction. Software developers must account for how clinicians want to wear the device in order to find a suitable interaction scheme. Nevertheless, it needs to be washable, resist disinfecants, and have a liquid ingress protection reaching IEC 60529 level IP67.

Having automated data capture at the bedside with real-time patient monitoring feeds to devices such as smart watches introduce a set of general problems related to control and situation awareness. Traditionally, ICU nurses have the role of filling out the patient chart to record the vitals of the patient manually. Nowadays automated patient monitoring and recording systems, which risk setting the clinician out of the information and control loop, is increasingly taking this role. Therefore, vendors are requiring that the nurses in the ICU environment validate automatically collected data coming from the patient monitors. This problem also applies to the to smart watches since an increased reliance on automated feeds may inflict on the formation on situation awareness. Hence, there is a difficult tradeoff that needs to be assessed between information feeds and direct information from the patient at the bedside.

Many studies have exemplified how clinicians create their own cognitive scaffolds as part of their practice\textsuperscript{21,22}. Common examples are the ubiquitous sticky notes that can be seen as external memories of work-to-do. Smart watch implementations should support flexibility and such cognitive practices. A problem here is that the smart watch is primarily an output device, which hamper the creation of small notes. A likely design solution is to create these notes with smart phones or tablets computers and use the watch for the reminder feeds.

A risk when introducing technologies that provide alarms is alarm fatigue\textsuperscript{23}. This is particularly apparent in the case of wearable technologies such as smart watches. For the Nurse Watch, we developed different alarms levels. This is probably only part of a solution to this problem. Since these are new devices, more research needs to be conducted on how smart watches affect alarm fatigue.

Conclusion

This paper presented a design and an evaluation of a smart watch platform for ICU nurses. Appropriately designed applications running on these unobtrusive devices can become important nursing information tools in the future. We exemplified two primary features – vital sign monitoring and work-to-do reminders – that were perceived by nurses to be useful in an ICU environment. Future work includes improvements to our alarm scheme and means for nurses.

Figure 5. The Kanban board and timeline of MODUS provides an overview of the checklist. The shown checklist items are intended to remind nurses to wash the patient regularly. Each upcoming task is also sent to the Nurse Watch as a notification. On the right side is two completed tasks visualized.
to create their own reminders to support their personal memory practices. Full in situ studies are required to appropriately assess the feasibility and usefulness of smart watches in the clinical environment.

Abstract

Utilization of patient-reported outcomes measures (PROs) had been limited by the lack of psychometrically sound measures scored in real-time. The Patient Reported Outcomes Measurement Information System (PROMIS) initiative developed a broad array of high-quality PRO measures. Towards reducing the number of items administered in measuring PROs, PROMIS employs Item Response Theory (IRT) and Computer Adaptive Testing (CAT). By only administering questions targeted to the subject’s trait level, CAT has cut testing times in half1. The IRT/CAT implementation in PROMIS is unidimensional in that there is a separate set of questions administered for each measured trait. However, there are often correlations among traits. Multidimensional IRT (MIRT) and multidimensional CAT (MCAT) provide items concerning several correlated traits, and should ameliorate patient burden. We developed an MIRT model using existing PROMIS item banks for depression and anxiety, developed MCAT software, and compared the efficiency of the MCAT approach to the unidimensional approach.

Introduction

There is increasing pressure for integration of the patient’s perspective in clinical research. An indication of this growth is the recent establishment of the Patient-Centered Outcomes Research Institute (PCORI) by Congress. PCORI’s goals include identifying the best available evidence to help patients and their healthcare providers make more informed decisions. Patient-reported outcomes (PROs) offer the patient’s perspective. The notion of the pre-eminence of the patient perspective has been prominent in literature for at least 20 years5-7. The research literature contains ample evidence for not relying solely on clinician reporting of patients’ subjective experiences. Discordance between patient and clinician reports of Health-Related Quality of Life (HRQL) and health status has been widely reported8,9. In general, clinicians have reported fewer symptoms10-13 and lower symptom severity14,15 compared to patient reports.

There is also increasing evidence that PROs can provide more information about toxicity and symptoms than physician or adverse event (AE) reports16,17. Studies have shown that, for some subjective symptoms (e.g., in sexual function), clinician ratings are no better than chance in predicting PROs of the same symptoms18,19. These findings support the need for tools to collect patient-reported symptoms and HRQL. The inclusion of PRO measures of AEs and other symptoms in clinical trials and other research recently has been recommended as a means to improve the quality and completeness of data, provide a more comprehensive reflection of patient experiences, and improve the operational efficiency of conducting studies20-22.

The need to reduce patient burden in measuring PROs has long been a concern in health outcomes research. This concern has led researchers away from reliance on classical testing models and toward item response theory (IRT) and computer adaptive testing (CAT). These methods have been used successfully for decades in education, licensure, personality assessment, and selection of military personnel. By only administering questions targeted to the individual’s ability or trait level, testing times have on average been cut in half while at the same time improving overall test reliability1. The efficiencies long noted in educational testing and credentialing are equally applicable in the measurement of PROs. Underlying every CAT is a bank of items “calibrated” to an IRT model. This model allows scores estimated from any subset of the entire bank to be expressed in the same metric. Therefore, although different individuals take different subsets of items, their scores are directly comparable23. In a CAT-based measure, an initial item from the bank is administered. A person’s response to that item provides a rough estimate of the person’s level of the trait being measured. For example, a patient who initially chooses the response, “Very Much,” when asked, “How much did pain interfere with your day to day activities?” is likely has a high level of pain interference24. The items subsequently administered would be those known to be effective in discriminating among people experiencing high pain. On the other hand, an individual who responded “Never” to this question would be asked additional questions known to be good at discriminating among people with low levels of pain interference. Because the CAT only administers the items that are most informative for each individual, patients can typically
complete a PRO CAT in an average of five questions with reliability similar to a traditional 15–25-item survey measure\textsuperscript{23}. Reducing the number of items on each instrument lowers the burden on patients and allows the measurement of more PROs, thereby supporting more comprehensive assessments.

The Patient Reported Outcomes Measurement Information System (PROMIS) is an initiative, funded by the National Institutes of Health (NIH) Common Fund, to improve assessment of self-reported symptoms and other health-related quality of life domains. CAT-based PROs have become much more accessible through PROMIS. A primary goal for PROMIS was the creation of CATs to enable efficient, psychometrically robust assessment of PROs for a wide range of health outcomes research\textsuperscript{25}. To achieve this goal, customized banks of items for measuring PROs were developed and tested at 12 primary research and data collection sites. Initially PROMIS developed and validated 27 adult and 9 pediatric item banks across the domains of physical, mental and social health. Many PROMIS instruments were developed by scientists who had previously authored well-known PROs including the Short Form-36, the Functional Assessment of Chronic Illness Therapy, and the Health Assessment Questionnaire. In practice, PROMIS banks have shown greater reliability, fewer ceiling and floor effects and more responsiveness to change than the “gold standard” instruments\textsuperscript{25}.

The PROMIS initiative lays the foundation for widespread health outcomes screening to take place in the waiting room of healthcare providers. These screenings can coincide with the current activities that usually occur while a patient is waiting for their healthcare provider, such as filling out or updating their past medical history and insurance forms. The data collected from these screenings can be incorporated into the patient’s electronic health record (EHR) alongside other clinical patient data. This will give healthcare providers a more accurate picture of their patients overall health and healthcare needs. Healthcare providers can make more informed decisions with regards to mental health referrals or treatment options.

In order to realize these benefits, PRO screenings must capture maximum information with minimum patient burden. PROMIS is unidimensional in that there is a separate item bank and therefore a separate set of questions administered for each measured trait. This has been a good initial step in addressing the issue of patient burden, but in the real world things are not always as simple as the one dimensional approach; that is, there are correlations between many of the traits assessed by the PROMIS system. For example, depression and anxiety are closely related\textsuperscript{37}, which means many questions that ascertain level of depression can also provide information about the level of anxiety. A multidimensional IRT (MIRT) model represents items concerning several correlated traits. A multidimensional CAT (MCAT)\textsuperscript{26-29} selects items from an item pool such that the items selected maximize information provided on several correlated traits. Such a model would significantly reduce the number of items administered in measuring PROs and thereby ameliorate the patient’s burden of answering many questions.

Researchers have recently realized the acute value of the MCAT approach in health services\textsuperscript{30-32}. In this research we investigated whether MCAT can lessen patient burden relative to unidimensional CAT (UCAT) in the domain of PROs. We performed this investigation using the related traits “anxiety” and “depression.” First, we developed an MIRT model for these two traits using existing PROMIS item banks. Then we developed MCAT software to administer questions based on this MIRT model. We compared the performance of this MCAT approach to the unidimensional approach currently used by PROMIS using 20,000 simulated individuals. We found that the MCAT consistently provided comparable estimates of anxiety and depression with fewer items, relative to administering separate UCATs.

**IRT and CAT Review**

Since the methodology concerns IRT and CAT, we first briefly review these two.

**Item Response Theory.** In item response theory (IRT)\textsuperscript{31,34}, we estimate an individual’s traits from the individual’s responses. Each trait is a skill, knowledge, or quality in some domain. For example, a trait may be “arithmetic ability,” while the responses are answers to arithmetic problems. Traits are hidden variables; responses are observed variables. Figure 1 shows a Bayesian network (BN)\textsuperscript{35} representing an IRT model with one trait $\theta$ (unidimensional) and five items.

The probability distribution of correctly answering a dichotomous item given the level of a trait is commonly modeled using the following two parameter logistic evidence model:

$$P(I_j = \text{Right}) = \frac{1}{1 + e^{-a_j(\theta-b_j)}},$$  \hspace{1cm} (1)

321
where $b_j$ measures the location of the item on the latent trait continuum (e.g., whether it is easy or difficult), and $a_j$ is a discrimination parameter reflecting how sensitive the item is to differences in the latent trait.

In the case of PROs there is no “correct” response. Instead, a polytomous IRT model is used to represent the probability of each option on the response scale. The probability distribution of a polytomous item with $m + 1$ categories given trait $\theta$ in the graded response model \(^3^6\) is computed as follows:

$$
\begin{align*}
P_{j0}(\theta) &= P(I_j \geq 0) = 1 \\
P_{jk}(\theta) &= \frac{1}{1 + e^{-a_j(b_j - b_k)}} = P(I_j \geq k), \quad k = 1, 2, \ldots, m \\
P_{j,m+1}(\theta) &= P(I_j \geq m + 1) = 0
\end{align*}
$$

where $b_{j1} < b_{j2} < \cdots < b_{jm}$. The probability of selecting option $k$, $k = 0, 2, \ldots, m$, is given by

$$
P(I_j = k) = P(I_j \geq k) - P(I_j \geq k + 1).$$

Traits in a given domain can be related, which means many items that ascertain the level of one trait can also provide information about the level of other traits. For example, many items that ascertain depression level can also provide information about anxiety level \(^3^7\). These relationships can be modeled using an MIRT model. In the case of MIRT, Equation 1 for the two parameter dichotomous logistic model is as follows:

$$
P(I_j = \text{Right}) = \frac{1}{1 + e^{-a_j(\theta - b_j)}}
$$

where $\theta = (\theta_1, \theta_2, \ldots, \theta_n)$ is a vector of traits and $a_j$ is a vector of discrimination parameters.

**Computer Adaptive Testing.** Computer adaptive testing (CAT) \(^3^8\) improves test measurement quality and efficiency by striving to administer optimal items to each examinee. CAT selects items sequentially to minimize the standard error of the estimate of $\theta$. Commonly employed item selection criteria used in CAT include maximizing Fisher’s information (FI) \(^3^9\), and using the Kullback-Leibler information \(^4^0\). Chen et al. \(^4^1\)
In unidimensional IRT, Fisher’s information for a polytomous item given trait level $\theta$ is as follows:

$$I_j(\theta) = a_j^2 \sum_{k=0}^{m} \left[ \frac{P_j(\theta)(1 - P_{j,k}(\theta)) - P_{j,k+1}(\theta)(1 - P_{j,k+1}(\theta))}{P_{j,k}(\theta) - P_{j,k+1}(\theta)} \right].$$

As indicated in this expression, information is a function of the individual’s standing on the latent variable $\theta$, which is unknown. To address the uncertainty inherent in the estimate of $\theta$, we computed the maximum posterior weighted information (MPWI), where the expected value of $I_j(\hat{\theta})$ is taken across the posterior distribution of $\theta$, which is unknown. To address the uncertainty inherent in the estimate of $\theta$, we computed the maximum posterior weighted information (MPWI), where the expected value of $I_j(\hat{\theta})$ is taken across the posterior distribution of $\theta$. The next item chosen is the one that maximizes the MPWI.

In the case of MIRT, FI takes the form of a matrix, and the determinant of the information matrix serves as a summary measure of the information regarding the set of traits. Thus, the next item is chosen that maximizes the posterior weighted determinant of the information.

**Methods**

The current study presents the result of a Monte Carlo simulation designed to evaluate the reduction in test length when using multidimensional versus unidimensional CAT. In order to represent a typical PRO assessment situation, we simulated responses to the actual PROMIS Anxiety and Depression banks. The PROMIS banks were developed using unidimensional IRT analyses. Therefore, an initial step toward building the simulation was to estimate the item parameters of a 2-dimensional MIRT model.

**Measures.** The PROMIS item banks were developed though a mixture of qualitative and quantitative methods. Rigorous scale construction practices were followed, with substantial input from domain experts, as well as revision based on respondent feedback. Statistical item analyses were conducted using both classical and IRT-based methods to identify the best items for inclusion in the final bank. Cella et al. The banks consist of 29 anxiety items and 28 depression items from the current PROMIS item banks.

For these items, respondents are asked to report the frequency of experiences during the past seven days. Examples of item content are as follows: “I was easily startled” (anxiety), and “I felt worthless” (depression). Responses were indicated on a 5-point scale (1 = Never, 2 = Rarely, 3 = Sometimes, 4 = Often, 5 = Always).

**Estimating the MIRT Model.** Calibrating an IRT model involves obtaining estimates of item parameters described in Equation 2. Unidimensional item parameters were available from prior work on the development of the PROMIS banks. For the MCAT, a preliminary analysis was conducted to obtain the necessary item parameters. Item parameters for a 2-dimensional Graded Response Model were estimated using the program IRTPRO.

This step utilized existing data collected for the development of PROMIS instruments. The sample was 52% female with a median age of 50. The racial composition was 82% white, 9% black, 8% multi-racial, and 1% other. Nine percent were Latino/Hispanic. The current study used a subsample of 7945 adults sampled from the general population who completed the anxiety and depression items.

The parameter estimates from the MIRT model were found to correspond closely to those from the unidimensional analyses (all correlations > .9). Items tended to have large discrimination parameters, indicating that each item was a strong indicator of the underlying trait. The average a parameter value was 2.78 (ranging from 1.41 to 3.76) for Anxiety and 3.23 (ranging from 2.21 to 4.72 for Depression).

Item location (b) parameters indicated that the items tended to reflect higher levels of anxiety and depression. For example, among individuals with a slightly below average level of the trait (0.5 SD below the mean), the most common response selected was the lowest option on the 5-point scale. This indicates that the items in this bank are primarily sensitive to moderate to high levels of anxiety and depression, and are less able to distinguish among individuals with low levels of anxiety and depression.

The preliminary analysis also yielded estimates of Anxiety and Depression levels for each individual in the data. The distribution of both anxiety and depression were positive skewed, with approximately 70% of individuals...
obtaining trait values near the mean ($\theta = 0$) or slightly below ($\theta = -1$), and the remaining 30% demonstrating higher levels of the trait. The two traits were highly correlated, $r = 0.88$, $p < 0.001$.

**Monte Carlo Simulation.** The simulation consisted of generating data for 20,000 respondents who completed both the UCAT and MCAT versions of the PROMIS Anxiety and Depression measures.

We first generated the true trait levels of each respondent by sampling from the bivariate frequency distribution obtained during the IRT calibration step. This approach produced simulated data representative of anxiety and depression levels observed in the general population.

Each simulated respondent was administered three CATs: MCAT for anxiety and depression, UCAT for anxiety, and UCAT for depression. First, an initial item was selected by the CAT algorithm. Next, a probability distribution for the individual was generated according to that individual’s true trait levels and the IRT model for that item. The IRT model corresponding to each CAT (i.e., unidimensional or multidimensional) was used to generate a probability distribution. Next, a response was generated according to this probability distribution.

After each item, the CAT then updated the posterior distribution of $\theta$ based on the individual’s response, along with the expected a posteriori (EAP) estimate $\hat{\theta}$, and the standard error (SE) of this estimate. This updated theta distribution was used by the CAT algorithm to select the next item. This was repeated for the first 20 items administered by each of the CATs.

The CAT was designed to stop when the SE of each $\theta$ estimate falls below a threshold. The SE is a measure of uncertainty in the trait estimate (i.e., how far the estimate is expected to fall from the true trait level). Consequently, when the SE falls below the threshold, this indicates that the trait has been estimated to an acceptable level of precision, and is unlikely to change substantially on further testing. For the current study, we considered a variety of thresholds, ranging from 0.2 to 0.4 in increments of .025. This range was centered on the threshold of 0.3 currently implemented in the unidimensional PROMIS CATs.

Two primary outcomes of interest were the number of items required to achieve the stopping rule, and the accuracy of the resulting EAP estimates, operationalized as the root mean square error,

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}[(\hat{\theta}_{Anx,i} - \theta_{Anx,i})^2 + (\hat{\theta}_{Dep,i} - \theta_{Dep,i})^2]}{N}},$$

where $\hat{\theta}_{Anx,i}$ and $\theta_{Anx,i}$ represent the EAP estimate and true value of trait $t$ for respondent $i$, and $N$ is the number of simulated respondents.

Results

An initial analysis indicated that not all simulated respondents reached the stopping rule within the 20 simulated items (see Table 1). This was particularly problematic for the more stringent stopping rules, which required a SE below 0.3. Further analyses revealed that the cases that failed to meet the stopping rule generally occurred when one or both of the traits were less than 0. As noted above, the items available in the Anxiety and Depression banks tend to be more sensitive to higher levels of these traits. The absence of items targeted toward lower levels of these traits limits the precision obtainable for individuals with below-average anxiety or depression. Thus, the administration of additional items is unlikely to change this result.

Because the outcome measures could be computed only for cases that met the stopping rule, respondents who did not satisfy this requirement were excluded from subsequent analyses. To ensure comparability, a respondent was included in the results only when the stopping rule was reached for both the UCAT and MCAT for a particular cutoff. However, the number of examinees was allowed to vary across cutoffs, so that more data was available for less stringent cutoffs (e.g., N=16,817 for SE<0.4) than for more stringent cutoffs (e.g., N=11,262 for SE < 0.2).

The average number of items required to reach the stopping rule is presented in Table 2. The MCAT required fewer items at each of the cutoff levels (differences were all significant, p<0.001). On average the MCAT required 1.2 fewer item than the UCAT. Furthermore, despite the reduced number of items, the MCAT and UCAT resulted in equally accurate trait estimates, as indicated by similar RMSE values. The greater efficiency of the MCAT is illustrated in Figure 2, which plots the RMSE against the average number of items required for each stopping rule. The lower curve for the MCAT represents greater accuracy given the same number of items, relative to the UCAT.

Discussion

The results of the Monte Carlo simulation clearly demonstrate the benefits of multidimensional adaptive testing for patient reported outcomes. Consistent with prior research\textsuperscript{28}, MCAT was found to produce accuracy similar to UCAT while reducing the number of items administered.

The absolute reduction in test length was considerable. The UCAT required 9 items on the average, while the MCAT required only 8 items. This corresponds to an 11\% reduction of the test length, which represents an important reduction in patient burden. However, the reduction in test length observed here is less that has been found in other MCAT applications\textsuperscript{28}. This may be due to the nature of the items examined in study. In general, each item provides considerable information about the trait. The small number of items needed to obtain precise trait estimates may limit the potential for refinements such as MCAT to reduce test length to the same degree as that achieved when there are a large number of items.

A strength of the current simulation is the use of actual items from the widely used PROMIS anxiety and depression banks to build the simulation, thereby enhancing the realism of the simulation. Nevertheless, the results represent only these two traits, and may not generalize to other PRO measures.

A distinctive characteristic of anxiety and depression is their very high correlation ($r=0.88$). It is possible that MCAT will demonstrate less benefit over UCAT when less correlated traits are modeled, because each trait will provide less information about the other. On the other hand, EAP trait estimates tend to be slightly biased toward the mean of the prior distribution, and this effect is heightened in MCAT when the traits are highly correlated. Therefore, MCAT with less correlated traits may exhibit less bias and greater accuracy. Further research is needed to replicate these findings with other combinations of traits.

The sample of participants for the current study was mostly white (82\%), and the generalizability of these findings across ethnic groups merits further study. Mean differences across groups should not affect the performance of MCAT assessments. However, if ethnic subgroups interpret and respond to items differently, this will affect the parameters of the IRT model, and consequently the accuracy of the IRT-based adaptive tests. Although there is evidence that measures of depression may function differentially across ethnic groups\textsuperscript{43,44}, little is known about the impact of these differences on UCAT and MCAT measures.

Abstract

Recently, in response to the rising costs of healthcare services, employers that are financially responsible for the healthcare costs of their workforce have been investing in health improvement programs for their employees. A main objective of these so-called “wellness programs” is to reduce the incidence of chronic illnesses such as cardiovascular disease, cancer, diabetes, and obesity, with the goal of reducing future medical costs. The majority of these wellness programs include an annual screening to detect individuals with the highest risk of developing chronic disease. Once these individuals are identified, the company can invest in interventions to reduce the risk of those individuals. However, capturing many biomarkers per employee creates a costly screening procedure. We propose a statistical data-driven method to address this challenge by minimizing the number of biomarkers in the screening procedure while maximizing the predictive power over a broad spectrum of diseases. Our solution uses multi-task learning and group dimensionality reduction from machine learning and statistics. We provide empirical validation of the proposed solution using data from two different electronic medical records systems, with comparisons to a statistical benchmark.

Introduction

Early identification of individuals who are at a higher risk of developing a chronic disease is of significant clinical value, as it creates opportunities for slowing down or even reversing the pace of the disease [1]. In particular, 80% of the cases of cardiovascular disease and diabetes, and 40% of the cancer cases can be treated successfully at an early stage [2], preventing the need for expensive medical procedures due to complications occurring during the standard care of chronically ill patients. This early stage intervention is also of significant cost value, as avoiding these expensive procedures and associated costs of care leads to a reduction in healthcare spending. In 2012, nearly 76% of Medicare spending was on patients, comprising just 17% of the Medicare population, with five or more chronic diseases: Alzheimer’s disease, cardiovascular disease, diabetes, renal disease, and lung disease [3].

Recently, one solution to this rising cost burden has been the introduction of incentive programs by an increasing number of self-insured companies, i.e., companies who pay for healthcare costs of their workforce. In 2013, 86% of all employers, which include Johnson & Johnson, Caterpillar, and Safeway, offered such incentivized programs. These programs involve, among many other aspects, incentivizing employees to undergo a health risk assessment (HRA) in order to identify employees with risk factors for major chronic diseases. The HRA typically involves collecting basic lab results like lipid panels, or other relevant biomarkers such as blood pressure, age, gender, height and weight. This data about the employee is then used to calculate risk factors based on simple clinical rules (see [4] for a list such rules). However, these simple clinical rules suffer from poor prediction accuracy since they rely on few biomarkers and do not account for risk variations in different populations, resulting in reduced efficacy of the program and undermining its objectives, suggesting the need for more effective methods for multiple disease screening and early identification. In particular, a false positive (mistakenly assigning high risk to a healthy patient) leads to unnecessary intervention costs while a false negative (mistakenly assigning low risk to a high risk patient) would be a lost opportunity to avert a large future healthcare bill to the employer, and it has been shown that higher predictive accuracy directly improves the cost-effectiveness of such programs [5].
Statistical data-driven methods present one principled way to obtain a set of biomarkers for such an assessment which provides high disease prediction accuracy. The use of such methods for disease prediction has grown rapidly over the past few years. An admittedly incomplete list of studies include: stroke prediction via Cox proportional hazard models [6], relational functional gradient boosting in myocardial infarction prediction [7], support vector machines and naïve Bayes classifiers for cancer prediction [8], neural networks for mortality prediction [9], time series in infant mortality [10], cardiac syndromes [11] or infectious disease prediction [12], and dimensionality reduction for unstructured clinical text [13]. However, these past works have focused on individual disease prediction, rather than determining a set of biomarkers which are jointly predictive of several diseases. While it is possible to combine the relevant biomarkers selected by each individual disease prediction model, this leads to a larger set of biomarkers than is necessary, and we will later show this is less cost effective than our proposed method.

In this paper, we present a method which relies on multi-task learning [14] model and group regularization [15]. The multitask learning model we consider allows for determining a small set of biomarkers which are optimal for prediction of multiple diseases, and is hence low cost. The model acts by learning the relevant biomarkers for multiple diseases simultaneously, while forcing these relevant biomarkers to be sparse [14, 16, 17], resulting in a lower cost model. Furthermore, it is known to be highly generalizeable and thus to adapt well to new data; we refer the reader to [18] for a detailed survey.

While these aforementioned works share methodology with our proposed method, to the best of our knowledge none have not yet addressed a setting where one desires to build a small, and thus low cost, universal set of features (biomarkers in our case) that can be used to predict multiple diseases. The work of [19] also considers multitask learning in the context of logistic regression and multiple disease prediction, however, their model does not enforce the disease prediction tasks to share the same set of biomarkers. Their model constructs a shared set of latent predictors as linear combinations of groups of features (diagnosis history) and a $\ell_1$ regularizer is used to ensure that each individual disease prediction relies on a small set of these predictors. Hence, their approach does not enforce a shared group of biomarkers to be used as predictors for all diseases, which makes their method less suitable for our purpose. Our model also uses the raw biomarkers as the predictors, which is more interpretable and enables our model to directly ensure that the set of biomarkers is small. Thus we present our proposed method as a solution to obtaining an accurate, low cost disease screening methodology. We evaluate our method on two patient populations, and compare the cost of our method to the current statistical benchmark, individual disease prediction. We find that our method has comparable, and in some cases improved, accuracy at much lower cost.

1 Methods

1.1 Patient Data

We considered two patient populations for developing our prediction tool, the Kaggle Practice Fusion dataset [20], which is publicly available, and the patient records from Stanford Hospital and Clinics, which will be referred to as the SHC dataset throughout 1. The SHC dataset consisted of 73,842 patients, and 1,313 possible laboratory exams; while the Kaggle dataset consisted of 1,096 patients with 285 possible exams; a comparison summary is given in Table 2.

The patient data from the SHC dataset was taken as follows. For each disease $j$ ($j = 1, \ldots, K$, with $K = 9$ for the SHC dataset), we collected the biomarkers of patients during a one-month period, which occurred during the year 2010 to 2011. These biomarkers included quantities such as age, gender, and the results of laboratory exams such as hemoglobin A1C, cholesterol, as well as blood cell counts2. If there were multiple laboratory exam results during this month, they were averaged. If patients had results over multiple months, we took the first month for which results occurred. If the patient was diagnosed with disease $j$ during this month, we removed the patient from

---

1 Due to HIPAA privacy restrictions, this dataset cannot be made publicly available.

2 However, we did not have access to biomarkers such as blood pressure, height, and weight.
the dataset, i.e., we only considered patients who had never had disease $j$ before the end of the month in which their results were taken. We collected these biomarkers into a vector $X_i$, $i = 1, \ldots, n$, where $X_{ij}$ took the value of the result of biomarker $j$ for patient $i$, and where $n$ was the total number of patients collected. We assigned each patient $i$ a label $y_i^{(j)}$ for each disease $j$, which we defined to be $+1$ if the patient has a positive diagnosis of disease $j$ within one to thirteen months, beginning the month after biomarkers were collected, and $-1$ otherwise. Lastly, we took the intersection over all diseases for which we collected patients. For the SHC dataset, we noticed that the set of patient-months for all diseases had a large intersection containing 75,619 patients, as shown in Table 2. Two of these diseases had an extremely low incidence in the Kaggle dataset, and were not studied when evaluating on the Kaggle dataset. These diseases are highlighted in Table 1 with an asterisk (*). The diseases we studied were obtained from [21, 22] and are shown in Table 1, with their formal names and abbreviations which will be used throughout this paper.

In the Kaggle dataset, due to lack of access to the exact time stamp for the lab results or diagnosis codes, the feature vectors $X_i$ were formed for each patient from the laboratory results and age information, without any use of temporal information. The label $y_i^{(j)}$ was determined by checking whether the patient had a positive diagnosis for disease $j$ in the system. Due to the small size of the Kaggle dataset, the bootstrap method was used to estimate the average and standard error of the AUC values.

For both datasets, the patients did not have results for all of the possible laboratory exams. In particular, the matrix $X$ has $98\%$, and $93\%$ missing values in SHC and Kaggle data respectively. To deal with the missing data entries, we used the standard method of mean imputation. We gave each the average value of the laboratory exam, where the average was taken over all patients who had taken the exam. We also repeated our analysis on Kaggle data set using multiple imputation (MI) with 100 imputations and the results were consistent. In particular, the relative accuracy of all algorithms and the sparsity of the models did not change. Finally, we standardized the observations so that the values of each biomarker have zero mean and variance one across the observations, which is a standard preprocessing step for many statistical methods.

### 1.2 Cost Data

Data for the cost analysis was taken from [23], maintained by Health One, Incorporated. Health One, Incorporated offers laboratory exams and has physical locations in all states in United States. Health One Lab’s website provides

---

3 We only restricted MI to Kaggle data set due to its high memory and computation requirement on SHC data. For mean imputation we exploited the fact that most entries of each column are equal and therefore $X$ is sparse. MI leads to a large non-sparse matrix that significantly increases memory and speed requirements. Results have been omitted due to space constraints.

Table 2: Comparison of SHC and Kaggle dataset
competitive prices of various laboratory exam packages, which are comprised of several laboratory exams. These prices were used to determine the cost of the set of laboratory exams which were selected by our methods to be the most important for disease prediction.

We emphasize that most laboratory exams are not sold individually but in packages. Thus, in order to find the cost of our screening procedure, we solved a set-covering problem, formulated as a mixed-integer optimization problem where we minimized the cost over the possible sets of packages but enforced the choice of packages to include all of the laboratory exams sought. This problem can also be formulated as a convex linear programming problem, but since the size of the problem did not lead to a computational impasse, the mixed integer program was suitable for our needs. More specifically, we solved the optimization problem given by

$$\text{minimize} \sum_{S \in \mathcal{S}} c_S q_S, \quad \text{subject to} \quad \sum_{S \in \mathcal{S}} q_S \geq 1 \quad \forall e \in \mathcal{U}, \quad q_S \in \{0, 1\} \quad \forall S \in \mathcal{S}$$

where $\mathcal{S}$ is the set of all packages, $\mathcal{U}$ is the set of laboratory exams for which we wish to obtain the total minimum cost, $c_S$ is the cost of a package, and $q_S$ is an indicator variable which indicates whether a particular package $S \in \mathcal{S}$ is chosen for inclusion. We solved this optimization problem using the software of [24]. We then calculated the cost of the laboratory exams by adding the prices of the set of packages $S \in \mathcal{S}$ for which $q_S = 1$ at the solution of (1).

1.3 Statistical Methods

We denote the different disease prediction models in this section as follows. We will refer to our main model as the multitask learning model (MTL). For each value of a tuning parameter, $\lambda$, this model selects $M$ biomarkers as relevant to the disease prediction. We derive a model from this, the ordinary logistic regression model (OLR-M), which takes as input data the results of the $M$ biomarkers which have been selected by the multitask model at each value of the tuning parameter, $\lambda$. We compare both of these models, the multitask model and the OLR-M model, to the results of solving one individual disease prediction at a time, for each disease. We will henceforth refer to this model as single task learning (STL), since this type of model only involves a single disease prediction. First, we begin with logistic regression (LR), a preliminary for our models.

**Logistic Regression (LR).** We briefly describe logistic regression, which we will denote by LR, before describing our methods. Given $n$ $p$-dimensional data vectors, $X_i$, and labels $y_i \in \{0, 1\}$, $i = 1, \ldots, n$, logistic regression finds the optimal values of a $p$-dimensional parameter vector $\theta$ and a scalar $b$ such that the conditional probability of the observing $y_i$, given the data $X_i$ for all data vectors $i = 1, \ldots, n$, is maximized. This optimization problem is given by: $(\hat{\theta}, \hat{b}) = \arg \max_{\theta, b} \{ -\sum_{i=1}^{n} \log(P(y_i|X_i; \theta, b)) \}$ where $P(y_i|X_i; \theta, b)$ denotes the conditional probability that one observed the label $y_i$ given the data observation $X_i$, which is parameterized by $(\theta, b)$. We will refer to this term as the likelihood. This probability is commonly given the form $P(y_i|X_i; \theta, b) = 1/[1 + \exp(-y_i(\theta^\top X_i + b))]$. This form of $P(y_i|X_i; \theta, b)$ is used in this paper.

**Single Task Learning Model (STL).** The single task learning model formulates the goal of maximizing the log-likelihood while keeping the set of nonzero elements in the parameter vector $\theta$ to be small. This model consists of a logistic regression and a regularization term, commonly known as the LASSO penalty [25]. In the context of disease prediction, for each disease $j = 1, \ldots, K$, where $K$ denotes the total number of diseases considered, the model finds the set of parameters that maximizes the conditional probability that a patient will be diagnosed with disease given his or her vector of biomarkers. More specifically, for each disease $j$, we solve the problem

$$\left(\hat{\theta}_j, \hat{b}_j\right)(\lambda) = \arg \max_{\theta_j, b_j} \left[ -\sum_{i=1}^{n} \log \left( \frac{\exp(y_i^{(j)}(\theta_j^\top X_i + b_j))}{1 + \exp(\theta_j^\top X_i + b_j)} \right) + \lambda \sum_{m=1}^{p} |\theta_{jm}| \right]$$

where as defined previously, $n$ is the number of patients, $y_i^{(j)}$ is an indicator of whether patient $i$ had disease $j$, and $X_i$ is the vector of biomarkers for patient $i$, of length $p$. The vector $\theta_j$ and scalar $b_j$ are the learned parameters for the model for disease $j$, with $\theta_{jm}$ representing the $m^{th}$ element of $\theta_j$. If $\theta_{jm}$ is nonzero, then the model has selected this element as relevant for prediction. The magnitude of the parameter $\theta_{jm}$ represents the importance of biomarker $m$ to the prediction of disease $j$, and the larger this value the greater its importance for achieving higher
prediction accuracy. The first term in (2) is the logistic regression, and the second term is the regularization term with \( \lambda \) as the regularization parameter. The value of \( \lambda \) controls the effect of enforcing, for a particular value of \( j \), the number of values of \( m \) for which \( \theta_{jm} \) are nonzero to be small. A larger value of \( \lambda \) encourages the effect more strongly. Note that a different model is learned for each value of \( \lambda \).

**Multitask Learning Model (MTL).** The multi-task learning model formulates the goal of maximizing the log-likelihood and enforcing that the set of biomarkers which is jointly predictive of all diseases of interest to be small. This model consists of a logistic regression and a regularization term known as the GLASSO [15], or group lasso, penalty. In contrast to the STL model, we jointly learn the parameters for all disease predictions, by solving the optimization problem given by

\[
\left( \hat{\theta}_1, \ldots, \hat{\theta}_k, \hat{b}_1, \ldots, \hat{b}_k \right) (\lambda) = \arg \max_{\theta_1, \ldots, \theta_k, b_1, \ldots, b_k} \left[ -\sum_{j=1}^{K} \sum_{i=1}^{n} \log \left( \frac{\exp(\theta_{j}^T X_i + b_j)}{1 + \exp(\theta_{j}^T X_i + b_j)} \right) + \lambda \sum_{m=1}^{p} \left[ \sum_{j=1}^{K} \theta_{jm}^2 \right] \right]
\]

where all variables are as defined previously. As with the single task learning model, the first term is a logistic regression, and the second term is the group regularization term, which encourages biomarker \( m \) to be either nonzero or zero across all diseases together, i.e. that for each \( m \), \( \theta_{jm} \) should be nonzero or zero for all \( j \). Larger values of \( \lambda \) enforce this more strongly. Intuitively, such co-variation of weights through this group regularization can be interpreted as transfer of information between different disease predictions during the training of the model and can further lead to greater generalization ability of the model. When \( K = 1 \), the penalty term then reduces to the penalty term in the STL model, and the parameters are learned for prediction of only one disease; thus, this model reduces to the STL model. As with the STL model, a different model is learned for each value of \( \lambda \).

**OLR-M Model.** The OLR-M model is derived from the MTL model. After solving for the optimal parameters \((\theta_{j1}^*, b_{j1}^*)\), \( j = 1, \ldots, K \) for the MTL model with parameter \( \lambda \), we retrained a truncated model, as follows. For each value of \( \lambda \), we determined the nonzero biomarkers, i.e., the values of \( m \) for which the quantity \((\sum_{j=1}^{K} \theta_{jm}^*)^2\)^{1/2} was above a threshold. We will denote this number of nonzero biomarkers by \( M \), and give further details on how the number of nonzero biomarkers was determined, in the section Learning the Model Parameters. We then retrained the model over only these \( M \) biomarkers for each disease prediction, \( j = 1, \ldots, K \), formulated as an ordinary logistic regression.

**Learning the Model Parameters.** The optimization package MinFunc [26], which utilizes spectral projected gradient, was used for solving the associated optimization problems of the considered approaches, given for the STL, MTL, and OLG-M model described below. For each value of \( \lambda \), all models were trained and tested using five-fold cross validation. During training, due to the lack of positive examples, in each cross-validation fold (or bootstrap sample, in the case of the Kaggle dataset) the training data was sampled so that, for the SHC dataset, the ratio of positive to negative examples in the training set was 1:1, and for the Kaggle dataset it was 1:3. The main performance metric for all prediction tasks is area under ROC curve (AUC). All demonstrated AUC values in the figures are cross-validated, thus averaged, AUCs.

For each value of the regularization parameter \( \lambda \), we considered biomarker \( i \) to have been selected by the model if for any value of \( j \), it had a nonzero value of \( \theta_{ij} \). We determined this as follows. For the MTL model, for a particular value of \( \lambda \), the number of nonzero features was determined by counting the number of biomarkers \( m \) for which the quantity \((\sum_{j=1}^{K} \theta_{jm}^2)(\sum_{j=1}^{K} \sum_{m=1}^{p} \theta_{jm}^2)\) was greater than a threshold of \( \tau = 10^{-6} \) for at least one value of \( j = 1, \ldots, K \). For the STL model, we considered a biomarker as nonzero if for some value of \( j \in \{1, \ldots, K\} \), \((\theta_{jm}^2)/(\sum_{m=1}^{p} \theta_{jm}^2)\) was greater than \( \tau \). Thus each value of \( \lambda \) corresponds to a set of nonzero biomarkers, and a cost can be derived via solving the optimization problem (1), as given in the section Cost Data.

## 2 Results

### 2.1 Biomarker Selection for Multiple Disease Prediction

We compare the results of the MTL, OLR-M, and STL models for disease prediction, number of biomarkers necessary to achieve the given results for prediction, and cost. As our evaluation metric, we will use area under
the receiver-operating characteristic (ROC) curve, henceforth abbreviated as AUC. The AUC values shown in the succeeding figures are averaged over the five cross-validation folds, as well as averaged over the nine different diseases of interest.

The MTL and OLR-M models achieve comparable accuracy to the STL model with a smaller number of biomarkers. Figure 1a presents this result visually, in which the given curves show the effect on the value of the AUC is when the number of biomarkers selected by the model is varied, for each of the different modeling approaches. This results also translates when considering the cost of the biomarkers needed to achieve each AUC value on the curve. Figure 1b presents the same result as Figure 1a, but calculates the cost of the biomarkers at each point on the curve in Figure 1b. Thus the effect is amplified when comparing cost of the MTL and OLR-M models to the STL model, as the MTL and OLR-M models are much lower in cost. The OLR-M was the most succinct of all the considered approaches, and in particular, the value $M = 30$ was found to be the optimal value for $M$ using cross validation to have the highest AUC, as presented in Figures 1a and 1b.

![Figure 1: Comparison of number of biomarkers selected and associated cost by the MTL, STL, and OLR-M models. Each point on each curve is obtained by changing the regularization parameter.](image)

2.2 Sensitivity Analysis

We study the effect of varying the length of, as well as a shift in, the time interval over which we identify a patient as having a positive diagnosis. In the previously presented results, the time horizon considered for diagnosis was one to thirteen months after biomarkers were taken. We consider a shift of a year, i.e. a time horizon of twelve to twenty-four months after the biomarkers were taken. We also study the performance when the time horizon considered is varied, one to six months, and one to eighteen months, after the biomarkers were taken. Due to space limitations, in Figure 2 we only demonstrate the results for twelve to twenty-four months interval and one to six months interval. In all cases, we observe the same pattern as in previous results.

We also compare predictive accuracy of the three models using other metrics than AUC. In particular, Figure 3 shows that the three models have comparable accuracy with respect to sensitivity (or true positive rate). However, with respect to positive predictive value, the MTL and OLR-M models are indistinguishable and closely follow the STL model.
(a) Cost comparison, diagnosis one to two years after lab results
(b) Cost comparison, diagnosis during a six month time horizon

(a) Average sensitivity versus fraction of selected patients
(b) Average positive predictive value versus fraction of selected patients

Figure 3: Comparison of predictive accuracy of models based on sensitivity and positive predictive value.

2.3 Biomarkers Selected for OLR-M Model

As aforementioned, the value of $M$ which achieved the highest AUC, when cross-validated, was $M = 30$. We have given a list of the top $M = 30$ labs selected by the OLR-30 model in Table 3. All of these labs are associated with the diseases of interest in this paper, and as expected from the design of our method, many of them are associated with several diseases. For example, abnormal glucose levels are associated with signs of diabetes, cancer, renal disease, liver disease, and heart disease. Similarly, abnormal alkaline phosphatase levels can be associated with liver disease, cancer, as well as heart disease. A vitamin B12 test can be given to those experiencing symptoms of anemia, as well as dementia and memory problems, but higher levels can also be associated with diabetes, liver disease, and heart problems. Additionally, the considered model also has the ability to discover associations between these biomarkers and the diseases which may not be explicitly known; hence, the associations go beyond known ones, some of which have just been mentioned.
Table 3: List of the top features with their rank determined by OLR-30. Smaller rank means the feature group received a larger value of $\sqrt{\sum_{j=1}^{K} \frac{\hat{\theta}_j^2}{\hat{\theta}_j^2}}$ in multi-task learning.

2.4 Generalizability of OLR-M to Different Patient Populations

We investigate the performance of the OLR-M model on a different patient population, the Kaggle dataset. As aforementioned, the Kaggle dataset is a less ideal dataset, with fewer biomarker values available per patient. As $M = 30$ achieved the best predictive accuracy and lowest cost when validating on the SHC dataset, we will use this model, and refer to it as OLR-30. The OLR-M model is able to achieve comparable accuracy to the STL model, with far fewer biomarkers, and thus has similar performance on this dataset as on the SHC dataset. The OLR-30 model consists of 30 biomarkers, as aforementioned, much fewer than the STL model, which requires the results of 63 biomarkers, in addition to age and gender information. Table 4 provides the confidence intervals at the 5% level for the AUC values for both models, for each disease under study. The results were obtained using 5-fold cross validation and the method of DeLong [27] for the confidence intervals.

Remark. The Kaggle dataset, as aforementioned, is a lower quality dataset than SHC, which required us to process the data differently than the SHC dataset as discussed in the section Patient Data. However, we observe that the results follow the same pattern as the results for the SHC dataset, as presented in Table 4.

3 Discussion

We have proposed two approaches, the MTL and OLR-M models, for developing a clinical model for multiple disease prediction. Our study has focused, in particular, on how to design a health-risk assessment (HRA) for prediction of multiple diseases, using statistical methods and patient data. In contrast to the STL model, which is one appealing and commonly used statistical approach in the literature, we propose a solution which relies on
group regularization methods to jointly learn a small set of biomarkers are the most relevant for prediction, for multiple diseases.

Although our results are encouraging, we note that our study has limitations. Although we would like to also compare the prediction accuracy of our method against common scoring rules, such as the Framingham score, used for individual diseases, we are unable to do so at this time because of the unavailability of necessary biomarkers in our data for these scores, such as blood pressure, whether the patient is a smoker, or whether they are on dialysis. Hence, we limit our comparison to the state-of-the-art statistical method for disease prediction, STL. The lack of temporal information regarding disease diagnosis in the Kaggle dataset is surely a limitation. Validation on this dataset has allowed us to compare the OLR-M and STL methods, however, we cautiously use these results to guide our conclusion that the OLR-M model is a viable option for a low cost multiple disease prediction model.

The results of our investigation show that the MTL and OLR-M models provide one solution to designing a lower cost HRA. We have presented experiments to validate that our models achieve comparable accuracy to the STL model, but achieve this accuracy with the use of fewer biomarkers, which directly translates to cost. Our MTL model uses group regularization to select a small set of biomarkers, which can be used to jointly predict all of the diseases at once. By learning which biomarkers are jointly successful for prediction, the MTL model is able to achieve comparable accuracy to the STL model, but with fewer biomarkers. The OLR-M model enhances these benefits by producing a model with fewer biomarkers than either of the other two considered approaches, and keeping a high accuracy by refining over the MTL model. Since the MTL model is a biased model, the OLR-M acts to remove the bias from this model, increasing accuracy of the MTL model at the points for which it has the highest AUCs.

The same pattern of results is observed when we consider different time horizons for considering a positive diagnosis of a patient, i.e, that the MTL and OLR-M models produce lower cost models with comparable accuracy. We have studied the performance of the approaches under a one to six month time horizon, as well as twelve to twenty-four months, when there is a lag of a year between when the patients’ biomarkers were taken and when the positive diagnosis occurred. We observed similar accuracy between the models as well when we studied the performance under other metrics, other than AUC.

Lastly, we have validated the OLR-M model on a new patient population, that of the Kaggle dataset. This dataset is a significantly smaller dataset, with fewer patients, fewer biomarkers per patient. However, we observe the same result to hold for this new dataset, as the OLR-M model is still as accurate as the STL model but much less costly. Thus we believe the the performance of the OLR-30 model is not restricted to the SHC dataset from which it was derived, but can be extended to new populations.

Abstract

Shift-to-shift handoffs refer to the process of transferring role and responsibility for providing care from one person to another, thus insuring continuity of care. Through focus groups of residents and supervising physicians, we studied how physicians select patient cases to discuss during handoffs. We also compared the selection across level of experience. Understanding the patient selection criteria can give us insight into how to improve handoffs, in particular using supportive technologies that are integrated into the clinical information system. Studying the actual handoff process and note-taking also generated suggestions for handoff improvement.

1. Introduction

Transitions of care can endanger the quality of patient care and patient safety. Care transitions occur between physicians during patient transfers from a ward to another, or during shift changes. The handoff process involves the transfer of role and responsibility from one person to another1. Communication modalities range from in-person encounters to phone calls or written sign-outs. Studies of adverse events established that up to 60% of preventable adverse events are related to communication failures2. Improving handoffs can be challenging, as the modalities and processes vary widely from one department to another.

This study focuses on the evening handoffs between usual day teams (Monday to Friday) and the night teams (who also cover Saturdays and Sundays). During this evening handoff, the dayshift teams discuss a selection of patients from their wards with the nightshift team in presence of the supervising physician, covering for the weekend. Not all patients will be discussed. Patients thought to be stable, for example, are usually not presented during evening handoffs. Weekend shifts work on the same model, with an additional written handoff for all patients on Friday evenings. While prior studies on handoffs have suggested ways to standardize the overall content of handoffs with the use of checklists3, for example, or to structure the presentation of each case with mnemonics4, little evidence supports the process underlying the choice of patient cases to be discussed.

Handoffs are complex procedures, requiring the integration of a large amount of information about each patient, and errors can lead to high costs. Job aids were designed to “extend human capability to store and process information5,” and have proved to be especially useful for tasks with these characteristics6. Yet, the design of useful job aids, which can help decrease the cognitive load, require a clear understanding of the tasks and reasoning procedures. As stated in the Cognitive Load Theory, “An element is anything that needs to be understood and/or learned. If elements interact, they cannot be understood in isolation7.” The multiple interactions between pertinent features contribute to the complexity of handoffs, and should influence how the job aid is designed.

Selective handoff processes, where only certain patients are handed off, emphasize the need for appropriate patient selection. Understanding this selection process can have implications both for educational interventions about the handoff preparation process, as well as for the design of supportive technologies. The current electronic medical records include many features, such as admission, progress and discharge notes, labs, radiology images and reports, reports of all other ancillary tests, nursing documentation, and a dashboard for the healthcare users. It does not, however, have a specific handoff tool. Notifications and alerts can be potentially used to help identify patients for handoffs, but the criteria for such notifications need to be well chosen, to avoid forgetting to hand off a patient, and to avoid alert fatigue8. The goals of this study are to identify patient selection criteria, and to compare the approaches of physician residents and supervising physicians. We present a framework for patient selection, which was similar across level of experience, and suggest ways

2. Methods

2.1 Data collection

After approval by the State ethical review board, we conducted four semi-structured focus groups of five to seven participants between February and May 2014: two with residents, and two with supervising physicians. We recruited participants from the Division of General Internal Medicine through emails and general announcements (i.e., prior to
grand rounds). We excluded the senior attendings, as they do not take part in the evening handoff process. Using eight standardized clinical vignettes of typical internal medicine patients, participants started by individually selecting the patients that they would hand off for both a weekday and weekend handoff session. The cases are detailed in Table 1. The choices were reported on a board to facilitate the group discussion. Then as a group, participants shared the reasons of their choices, and reached a consensus handoff. We completed the session with an open discussion about more general questions on personal experiences, in particular during their on-call months, during which they were on night and weekend shifts. We also enquired about the importance of the order in which cases were handed off, and whether handing off to a supervising physician (rather than a resident or medical student) would have affected the content. We asked about the use of mnemonics for the verbal handoff. All sessions were conducted in French.

2.2 Study setting

Medical teams in the Department of General Internal Medicine at the largest Swiss teaching hospitals organization are responsible for patients throughout the day from 8 am to 6:30 pm during the week. At 6 pm, the day teams hand off their patients to the nightshift resident. The Department is split into two zones, each of which is managed by one nightshift resident until the next morning. Each nightshift resident cross-covers about 80-90 patients from five different wards, which means they are responsible for all of these patients, regardless of whether they are familiar with their cases or not. Although nightshift residents have in-house supervision, the supervising physician actually works in the Emergency department, and usually only discusses urgent or complex cases with the nightshift residents.

Between Mondays and Thursdays, day teams typically leave written progress notes as needed, i.e. for a procedure performed during the day like a pleural tap, or for a new management approach. On Fridays, however, all day-teams are required to leave a full progress note for each patient, which also serves as a written handoff, since it also includes which parameters to monitor, tests results to track, and a general list of problems.

2.3 Data analysis

All discussions from the focus groups were transcribed and de-identified for subsequent coding with thematic content analysis. Two of the investigators coded the transcripts, iteratively comparing and contrasting themes
between individuals, cases and focus group sessions. We also analyzed according to the level of experience (resident vs supervising physician). The results of individual patient selection from the board were also analyzed using descriptive analyses, and a multi-rater kappa analysis by level of experience.

3. Results

3.1 Participant characteristics

We enrolled 12 residents and 10 supervising physicians. Residents had an average of 2.8 years of postgraduate clinical experience (range of 1 to 5 years), and supervisors had an average of 6.8 years of experience (range of 5 to 9 years), with 2.4 years on average of supervision. These levels of experience are representative of the current physicians in our Department (senior attendings not included in this study), with board certification occurring on average after 5 years experience. There were 7 female supervisors, and nine female residents. Six supervisors and three residents reported some prior handoff training. All participants had completed at least one 3-month rotation in emergency medicine.

3.2 Patient selection

Our study focused mainly on patient selection for verbal handoffs. Participants identified several criteria to help identify patients that needed to be handed off to the night-shift physician or weekend teams. Despite some degree of overlap, we can categorize the criteria. A) related to patient safety, such as unusual or complex cases, or information that might be difficult to find in the EMR. B) related to care workflow, such as tracking tests results, or clinical monitoring. C) related to acute situations, with recent aggravation or unstable patient that need close monitoring. D) patient comfort, and end of life care. Finally, E) related to the prevention of complications or F) events that are anticipated. These themes are illustrated in Figure 1.

![Figure 1. Criteria for patient selection.](image)
Patient safety

Patient safety involves issues in clinical reasoning and information retrieval. Participants handed off cases with atypical management, to avoid confusion or even errors by the night shift physician. Supervisor SP3 explains: “We had to choose an unusual antibiotic for one of my patients, a choice that could have been questioned by the night physician... Sometimes, when we explain why we decided to choose B rather than A, the night-shift physician won’t waste time wondering why the day-team chose this or didn’t do that. So I like to handoff unusual approaches.” SP5 also gave an example of this: “For patients with fever of unknown origin, we want to avoid antibiotics. The spinal reflex for fever usually is to administer an antibiotic. So I like to hand off when to give which antibiotic, and to explain why we choose to NOT give an antibiotic to someone with fever.”

Cross-covering physicians are not familiar with the patients they are responsible for, and are often under time-pressure. Day-time physicians are much more familiar with the patients’ conditions and have time to discuss patient management with their supervising physician and consultants. Providing a brief explanation for certain diagnoses can help the night physician make decisions, or at least help save time when reviewing the medical charts. One resident (R11) said about a patient with chronic hypokalemia from renal loss: “The day-physician who has been managing this patient over the last week knows her situation by heart, particularly for potassium substitution, whereas the night doc may not have the time to review the case in depth.” R3 describes her own experience during night-shifts: “It’s not because we don’t want to think, it’s just to help understand where the problem lies because nights are busy, we are not familiar with the patients, and sometimes it’s just tricky to go over the whole story when it’s urgent.”

Another reason to hand off a patient was if they thought that some medical information might be difficult to find in the EMR. For example, SP2 reported an example with dialysis: “For dialysis, the information needs to be more detailed. Urgent dialysis takes place in the ICU. So for patients – I remember this patient who had a “Do not resuscitate” order, yet would have been admitted to the ICU for urgent dialysis. It wasn’t well handed off, and that information was hard to find...” The goal then of handoff in this case would be to raise awareness about certain aspects of patient management.

Care workflow

Participants also handed off patients who had pending imaging, on-going labs or other tests, so that the on-coming physician could track results in a timely manner, and adapt a patient’s management if needed. SP5 discusses tracking as a handoff goal: “[...] tracking exams that have been ordered, so there’s no chest x-ray with a white-out that is missed until the following morning. So pending lab tests and imaging should be tracked by the night-shift to avoid late discoveries.”

Acute care

Patients who were considered unstable, or who had a recent aggravation of their clinical state, were also handed off. R9 explained: “Something acute is happening, and we are starting initial measures. But we need to see how the patient will respond to all this, so we can’t assess if the patient is stable or not at this time.” Handoffs allow patients to be seen rapidly for an initial assessment, and then to be monitored during the night, ideally with clear recommendations for pain, blood pressure or diuresis, for example.

Receiving a handoff about an unstable patient also helps the on-coming physician to attribute priorities to the numerous tasks she has to accomplish. The day team sometimes emphasizes the need to see a patient soon to reassess the situation. As stated by one supervising physician (SP5): “One of the goals of handoffs is to help the night resident decide the order in which to do things. By handing off [an unstable patient], she might start by assess this patient, rather than just come across her later during her shift, and he might realize that the diuresis decreased over the past two hours. If instead she does receive a handoff about this sick patient, she might go see her earlier.” Nursing concerns can also contribute to a physician to hand off a patient. Nursing teams are more present at the bedside than physicians, and may be more able to assess changes in status. Nurses are also often the first person to detect or suspect a cause for concern in hospitalized patients. In the case with suspected lung cancer, SP4 explains: “I would hand off this patient because the nurse assessed him to have increased shortness of breath. It’s a vague symptom, and because it’s vague, I will probably need to hand him off for more investigation. I believe the day resident should go and evaluate the patient, to gather more information, so that the night physician can reassess the patient later in the evening. There may also be a chest X-ray to track.” In this example, we see that there are often several reasons to hand off a patient, first due to a yet unexplained aggravation in the clinical status, which then needs clinical monitoring by the night physician and potential test result tracking.
Prevention

In order to maintain continuity of care for patients, participants emphasized the need to anticipate potential problems during the night or weekend. Anticipation requires good knowledge of a patient’s case, where recurrence of an event is possible, or with good knowledge of a clinical situation, such as a common complication of a procedure. An example of a recurrent event, is described by a supervising physician (SP2): “[... because this patient had a high probability of presenting another episode of agitation, he’d had them often in the past.” Another supervising physician anticipates a complication of a recent intervention: “I would discuss this patient simply because he had an intervention the day before, and because he’s still in the time frame for a complication. It’s not just the pain, it’s also about seeing if there’s bleeding or a hematoma” (SP4)

Patient comfort

Participants also agreed that patients with end of life care should be handed off, so the night shift physician could (1) assess patient comfort and adapt treatments if needed, (2) not be alarmed if the nurse calls about the time of death, and (3) be aware who to inform about changes in condition or death (and in what delay this needed to be done). As illustrated by SP10’s statement: “It’s to let us know that if the clinical state worsens, to provide end of life care rather than aggressively reanimate. It’s also to inform about whether the family wishes to be called any time of the night, to know where to find their phone number…” (SP10)

Other reasons, divergent opinions and use of written handoffs

Other reasons to handoff a patient were to inform about patients with multiple or recurrent symptoms of unclear origin (after excluding the treatable or urgent etiologies), such as “chest pain, which has already been worked up several times, cases where clinicians tend to worry and begin the work-up all over again each time the symptom appears” (R9).

Physicians also reported relying on nursing teams for part of patient monitoring. In some situations with divergent opinions about handoff, some clinicians advocated mainly relying on the nursing team, providing clear targets for monitoring, and expecting nursing teams to call the night physician if the targets were not reached. SP1 described this for the case with sepsis: “[…] an acute event in a hospitalized patient […] after a clinical assessment, I would decide about prescribing an antibiotic and close nursing surveillance for blood pressure and diuresis. I think the nursing team has a role to play here, and it’s the nurses who will call the doctor if needed. So for the night physician, I don’t see what more the doc could do if just checking in spontaneously, if the monitoring targets are well established.” For other participants, handing off such a patient was a potential a teaching moment for the night resident, about what to do if the targets were not achieved. Handoffs in this case were also about deciding when to call the ICU to transfer the patient.

In several of the discordant opinions about handoffs, the debate was not so much about whether to hand off a patient, but more about whether the handoff should be verbal or written. Oftentimes, simple to-dos such as weight monitoring or labs to track are not handed off verbally, but will be highlighted in the written handoff notes for the weekend day physicians.

3.3 Resident vs supervising physician approach

Overall, there was clear agreement on the ultimate goal of handoffs, which is to maintain continuity of safe and effective healthcare. Participants also clearly stated differences in patient management during day and night shifts, where night teams manage the acute events, and follow recommendations made by the day teams. During the day, patient management includes a more in-depth study of patient cases, addressing more chronic issues, work-up, and discussions with consultants.

Using descriptive statistics, our results show similar proportions of evening handoffs and weekend handoffs between residents and supervising physicians. (Figure 2)
Figure 2. Proportion of cases handed off by level of experience. There was no significant difference between cases selected by residents or by supervisors.

The multi-rater kappa statistic showed moderate agreement for patient selection among residents and supervisors for both weekday evening handoffs (0.53 and 0.65 respectively) and for weekend handoffs (0.44 and 0.58).

Handoff rates were lower during the weekends. In our usual practice for weekends, day-teams prepare a written sign-out for the weekend teams, with a summary of current problems, and a list of to-dos, with the context (relevant past history). A complete sign-out is often not prepared for weekday handoffs, and only a brief note is left when a procedure is performed or if the patient’s condition changes.

3.4 General comments about handoffs

There was also an overall agreement about the content of a verbal handoff. They were expected to be concise, with clear day-team recommendations for anticipated problems (if-then statements) and a to-do list of tasks, such as tracking a lab or other ancillary test results, or clinical monitoring. Participants all felt that keeping handoffs brief helped to avoid “diluting” the information.

While there is no formal handoff training in our institution, clerks and residents receive a pocket card with a mnemonic for handoffs when they start their employment in our department. This mnemonic suggests a way to present the verbal handoff, but does not concern the patient selection process. Participants did not use this pocket card or mnemonic, some barely remembered having this card, because they considered that their current process was close to the recommendations in the mnemonic (“I read the card, and it seemed to resemble what I currently do, so…” R2). The card seemed to have more use as support when explaining handoffs to the medical students. Day teams sometimes discuss the patient selection with the supervising physician. The handoff itself can be given by a resident, a final-year clerk, or more rarely by a supervising physician.

The order in which patients were presented did not matter to the participants, as they mainly needed to know the ward in which the patients were. Participants all confirmed the importance of interactions during the handoff, for clarification about recommendations, general management decisions, or simply for precision.

Participants mentioned the importance of taking notes while receiving handoffs, as a way to remember key features for a patient. The current practice for note-taking in our practice is to start with blank paper. Participants usually ask the day teams to give the ward name before beginning their handoff, in order to take notes at the right place in their sheets. In most cases, the handoff begins with the name of the patient, year or date of birth, resuscitation order, followed by medical information and “to-do list”. Although the spelling of patient names may be incorrect, and despite potentially missed items while annotating, participants were quite satisfied with the current process. There is no access to the electronic medical record (EMR) during the handoff, but participants reported using the EMR after the handoff process to clarify the information received, if uncertainties remained after the handoff process. Both residents and supervising physicians mentioned that improvements in handoffs should not lead to an increase in workload for the day-teams, particularly since many already work overtime on Fridays preparing written handoffs for their patients.

Last but not least, participants agreed that knowing who they are handing off to can change the content of the handoff. Clinicians tended to provide more detailed information to junior physicians, with more recommendations.
4. Discussion and design implications

Understanding the residents’ and supervisors’ perceptions and expectations of the handoff process is the first step to improving handoffs. Participants agreed on the main goal of handoffs, which is to maintain the continuity of care between day and night teams through a transfer of responsibility. Therefore, there was overall agreement over the need to (1) identify patients at risk of possible serious events in the near future, (2) explain unusual or complicated reasoning processes, (3) identify patients with pending tests, and (4) provide recommendations for the night or weekend teams, in particular with explicit if/then statements.

Improving handoffs can be achieved through combined approaches. We propose ways for supporting handoffs in Figure 3.

Figure 3. Approaches for improving handoffs. Dark blue boxes describe the sequential steps of handoffs, whereas the white boxes suggest approaches to support each step.

Support for patient selection:

Supportive technologies for handoffs can address some of the patient selection criteria used to identify patients who need to be handed off. Despite an overall agreement about these criteria based on our standardized clinical cases, many criteria are based on clinical reasoning processes, standard processes in patient management and on the expected evolution over time. Providing technological support for these criteria may therefore be more difficult than for other criteria such as pending tests.

Simple notifications or alerts could be created for patients who await some kind of imaging or lab test, or who have had a test with a pending result. If these notifications are visible in an overview mode, they could help the day-team identify patients to hand off for result tracking and subsequent management. Designing such a system could have additional benefits for certain time-consuming tests, such as cultures for mycobacteria, which can take several weeks or months. Currently, some of these results may be missed altogether; or they may be seen by the hospital physician but not the ambulatory physician if the patient has been discharged. Receiving some form of notification for these tests could help improve the communication process.

Anticipation seems to be a key component for patient selection for handoffs, as it is required when assessing risk of problems occurring in the future. Anticipation requires an understanding of the patient’s diagnoses, and of how they will evolve over time. Clinical evolution of a given diagnosis has been studied in the form of clinical pathways, or trajectories\(^\text{10}\). We could imagine having a supportive system that could notify the physician when a patient’s evolution diverges from a clinical pathway. For example, for patients with pneumonia, fever should abate within 72 hours of the start of antibiotics. If this is not the case, the supportive system could notify the day physician as she prepares for handoffs at the end of the day. Ideally, not only vital signs, but also lab results should be integrated in the expected trajectory. The difficulty, however, is that the effect of a patient’s comorbidities and age on the time-frame of the trajectory is less well studied. Furthermore, it is not just the absolute value that is of importance for a trajectory, but its relative value, particularly for changes in settings with chronic diseases (i.e., creatinine values with
and without chronic kidney disease). This trajectory-based approach has been discussed also for patient prioritization\(^\text{11}\), when a physician chooses the order in which to perform daily tasks for a set of patients.

Another advantage of this trajectory approach would be its ability to detect early warning signs for a patient starting to be unwell. Although nurses take the vitals during the nursing rounds, changes in status may not be immediately apparent, or may initially go unnoticed if the change is small. There may then be a delay until the doctor sees the change, or until the nurse discusses her concern with a doctor. A trajectory-based approach could also serve as an early warning system for patient deterioration.

One of the main challenges about notifications and alerts is the target physician and the threshold to activate the alert. We propose that for handoff support, day physicians should see a notification in an overview mode of the ward. The cause of the notification (pending tests vs divergent trajectory) should be visible, with easy access to the pertinent part of the chart for clarification. Another challenge about notifications is the threshold of abnormality\(^\text{12}\), particularly for easily fluctuating variables such as pulse or blood pressure.

Notification systems about pending results or divergent trajectories would benefit greatly from a global view of the patients in a ward. For the nightshift team, this could even be for all 4 or 5 wards that they cross-cover. The current EMR system at our institution has two overview modes for a ward: the first mode is a table, which lists all patients in a ward in an alphabetical order, with information on gender, date of birth, and date of hospitalization. The second mode is a synoptic view with the rooms and emplacement of patients within the ward. It also contains information about patient flow, with lists for the in-coming and out-going patients. The nursing version of the synoptic view already has information about whether new orders have been placed and whether they have been carried out by the nursing staff. This synoptic view could also present information about pending tests or pending results for each patient.

The form of notification is also important, in particular to avoid information overload\(^\text{13}\), or alert fatigue\(^\text{14}\). We propose a design with more subtle modified background for a trajectory-based approach, with hues according to divergence with the planned trajectory. Thus, the system informs the physician about a degree of “sickness” or of need for attention without giving explicit notifications or recommendations. Humans interpret a value quicker in a graphic form than in a text form, such as alert messages\(^\text{15}\). Furthermore, this graphical representation reduces cognitive workload\(^\text{15}\). The visual representation may further point to more detailed, textual information. For the pending test results, we propose a notification on the overview pages only, as our EMR summary cockpit page presents the most recent results, with an agenda for future tests.

Detection of unusual or complicated patient cases is difficult to support through technology. Our system currently does not track the number of consultants involved in a patient case, but this could be a proxy for the complexity of a case. The trajectory-approach, if detailed enough to identify therapy choices, could possibly be a way to help detect unusual patient management strategies. The choice of antibiotics, for example, could help differentiate a standard management from an usual process (e.g., resistant bacteria). On the other hand, physicians can usually identify unusual management choices, and may not need supportive technologies for this selection criterion.

**Support for handoffs**

Although observing the actual handoff itself was not the main goal of our study, participants all did mention taking notes when receiving the handoff. The preparation for the handoff could also include a written component, which could help improve the note-taking process. While we recognize the desire and need to make personal annotations about each patient, according to individual mental models, we also see potential areas for improvement. We could imagine using a print-out with key words, patient identity and basic demographics for the selected patients, for example.

As our hospital prepares mobile versions of our current EMR, we can suggest a design of brief patient summaries, easily extractible from progress notes or problem lists for each patient. By providing the patient name, and main problems, we hope to help the receiving physician focus on the handoff. These key problem lists should be expandable, thus providing information about the evolution, ancillary tests and consultations from the medical specialties when required. We do however need to avoid overwhelming the receiving physician with the written information, which (1) is a distraction from the verbal handoff, and (2) should not require additional paperwork for the day teams. Designing for mobile interfaces, due to their limited screen size, requires mindful selection of the pertinent information. The physician may access the deeper levels of information (i.e., specific laboratory results, more detailed information about on-going work-ups) when required by using the touch screen. Mobile devices may thus respond well to the needs of physicians during handoffs.
4.1 Limitations

The generalizability of our findings is somewhat limited by differences between our local practices and those of other institutions, particularly in terms of work organization and local EMR system. This variability in handoff procedures is a barrier to handoff improvement, and has motivated recommendations for standardization. Although some EMR systems may already have parts of the features suggested here, we have presented design implications that are based on our local EMR system, with which our physicians are familiar. We also note the use of fictitious cases, based on short vignettes, which differ from real patient cases that physicians manage. Although focus groups can lead to biased discussions due to peer pressure, we included an individual selection phase prior to the group discussion. We had a slightly higher representation of female physicians in our sample compared to our actual population, in both resident and supervising physician groups, which may affect some of our results.

Among the strengths of this paper, we note the local practice of patient selection for handoffs, which emphasizes the anticipation of potential problems in the patients near future, and allows the clinicians to keep their focus on the sicker patients. Even if this patient selection process may not be found in other healthcare models, our findings can help guide improvement in the handoff content, by focusing particularly on the features we identified for patient selection. We did reach saturation with our four focus groups. Furthermore, the use of standardized cases for the discussion allows for a comparison across focus groups and across level of experience. Participants found the cases realistic, and could relate to similar situations in their own experience.

5. Conclusion

Our focus group sessions with residents and supervising physicians used standardized patient vignettes to help study how physicians assess and anticipate needs in patient management. Patients considered to be unstable, or with yet unclear evolution after an acute event, those with unusual management strategies, those with complex medical cases, those who need monitoring or follow-up on tests, and end of life situations are selected for discussion during handoffs. Better awareness of these situations could help facilitate the handoff preparation process.

Future works

Based on our findings in this study, we plan to conduct usability studies with our new design implications for supportive technologies for handoff preparation. Using a mock-up of our current EMR, we plan to assess physician impressions and usability with the suggested changes, in particular for the synoptic view of an entire ward with notifications. Implementation of the notifications or alerts suggested above will require not only changes in the EMR system, but also further reflection how to reach the appropriate target, and will take much longer for implementation.

After studying the handoff preparation process, we are currently conducting a study on the integration of verbal handoff information, with the subsequent chart-biopsy process during cross-covering, followed by the participants giving their own handoff. We are comparing two interventions with the current note-taking (control): EMR access during the verbal handoff and use of a paper summary as suggested above (including patient identification and a list of problems). Studying the participants’ handoffs in this new study will provide further insight into the handoff preparation process.

¹University of Washington, Seattle, WA; ²Brigham Young University, Provo, UT, ³Medico Systems, Bellevue, WA, ⁴University of Texas, Houston, TX

Abstract
Rigorous methods for design and verification of health IT systems have lagged far behind their proliferation. The inherent technical complexity of healthcare, combined with the added complexity of health information technology makes their resulting behavior unpredictable and introduces serious risk. We propose to mitigate this risk by formalizing the relationship between HIT and the conceptual work that increasingly typifies modern care. We introduce new techniques for modeling clinical workflows and the conceptual products within them that allow established, powerful modeling checking technology to be applied to interactive health IT systems. The new capability can evaluate the workflows of a new HIT system performed by clinicians and computers to improve safety and reliability. We demonstrate the method on a patient contact system to demonstrate model checking is effective for interactive systems and that much of it can be automated.

Introduction
The importance of interactive computer systems in healthcare has grown rapidly with the proliferation of networks of personal devices, laptops, and desktops. Rigorous methods for design and verification, however, have lagged far behind. Standard methods, such as usability testing, that were adequate for interactive systems used in business offices and homes, were never intended for safety-critical domains 15, 16. The inherent technical complexity of healthcare, combined with the added complexity of health information technology (HIT) makes their resulting behavior unpredictable and introduces serious risks 1. These risks threaten patient safety, disrupt care, undermine the added value of HIT, and impede its adoption.

Model checking is one technology that has great potential to help mitigate the risks of unpredictability in complex safety-critical systems 12, 13. A model checker proves whether a subject system satisfies the properties that it needs to meet in every possible behavior of the system. Applying model checking directly to interactive systems that are employed by clinicians, however, presents distinct challenges. One of the most severe is the difficulty to define clearly the conceptual work, such as disease diagnoses, treatment plans, surveillance, case-management, hospital admissions, and schedules for scarce equipment that is common in modern healthcare. Clinical workflow studies have shown these types of conceptual work products to be fundamental in HIT and care.

Until recently the problem of how to specify conceptual work products in a sufficiently rigorous manner prevented model checking of interactive systems for this aspect of care. Theoretical advances in cognitive science 17 combined with standards for declarative knowledge modeling 7, 21 now offer a technique to clearly specify conceptual work products (CWP), which in turn enables model checking for interactive HIT systems. The technique, presented in this paper, builds on earlier work that innovated CWP specifications as reference models to guide the design of interactive systems with workflows performed by human and machine agents 9. Early successes solved difficult design problems in aircraft schedules that integrate flying missions with aircraft maintenance 8, online self-support for users of personal computers with software problems 10, case management for MS outpatients 11, and NASA’s planning system to coordinate maneuvers of the International Space Station 5.

We introduce a new evaluation criterion for model checking interactive HIT systems using the CWP it is supposed to produce. A CWP can be specified using standard domain modeling techniques 7 for a clear description of a valid starting state, a valid ending state, and intermediate states that describe its acceptable evolutions. Importantly, the CWP abstraction tells us what must be accomplished by an HIT system independently of how it is accomplished. Rather than checking the state of a machine, the focus is on the state of the CWP as clinicians and their computing devices transform it to its goal state. Intuitively, this new approach shifts verification focus to the work intended to be accomplished by an interactive HIT system by proving that it accomplishes the work declared in the CWP.

To date, much of the research with model checking in health care has focused on formalizing workflows and proving temporal properties on workflows 2,3,19 or on developing new modeling languages to describe workflows and human machine teaming in those workflows 6, 12. A key principle of the new approach is that the CWP has states that are defined by combinations of attribute values that are independent of the means to attain them in the
workflow. This allows established model checking to be extended verify workflows that have both human-performed tasks and machine-preformed functions with vastly different capabilities in the same model. This new capability has potential to bring new levels of safety and reliability to HIT systems.

In the remainder of this paper we give an overview of the new method, illustrate the new techniques for modeling workflow and CWP with a small, interactive system, and describe a proof-of-technology study of the new model checking approach. We conclude by discussing the benefits to safety of HIT and to software engineering more generally, and outlining the next steps for research.

**Overview of the New Method**

We conducted a study of how to extend established model checking technology to exploit CWP as the evaluation criterion. Our objective was to determine whether CWP could serve as the evaluation criterion without making major changes to model checking technology. Our initial study assumed normative performance on all tasks by both human and machine performers. Our rationale was if a system could not check out under ideal conditions it did not merit further checking until it was improved. The functional components of the new approach in the study are shown in figure 1.

![Model Checker Components with CWP](image)

As shown in figure 1 the components have two main groups: Product & Process Models of the interactive system on the left, and the Verification Components on the right. The components for verification are widely recognized as well-established in effective practice for electronic and for software such as distributed systems. These verification components prove whether a transition system implements a specification.

The Process & Product Models on the left are two complementary innovations: for representing the products of the conceptual work of clinical care; and the workflow processes performed by clinicians and computers that create those products.

1. **MATHflow** is a graphical process diagramming tool that integrates models of clinical workflow with the use and change of information resources. There is growing interest in process models of workflow to analyze and design HIT. MATHflow is a partial implementation and an extension of the OMG’s recent standard for Business Process Modeling Notation (BPMN), which was created to support the development of software requirements for people working in groups that are supported by computing. As shown in figure 4 the MATHflow extension adds a properties editor for each task in a workflow to enter attributes to represent the information the task uses, the containing resource where each was accessed, and the destination information resource if the task changes any attribute values. The associations among tasks, attributes, and information resources are automatically recorded in MATHflow’s information dictionary.

2. In the terminology of knowledge representation a CWP is a declarative specification, as opposed to procedural specification of how-to do something. Rummelhart and Norman were among the first to report scientific
evidence that knowledge of what is learned and stored differently in human memory than the knowledge of how-to do things. CWP complement and complete procedural workflow models of care by making their purpose clearer and more meaningful. Generally, a workflow is constrained by the product it is supposed to produce because it implies so much about the activities and resources that are needed in the workflow. In the terminology of BPMN a CWP is a specification of a token, i.e., the entity that flows through a workflow process of task activities that operate on it to change its state. We use the term “conceptual work product” to mean the entity as it evolves through all its intermediate states to reach its goal state. In task-analytic methods such as TURF, a CWP corresponds to the work domain ontology 23. Complex CWP may require formal ontology modeling languages, such as OWL 21, while simpler CWP can be specified with standard declarative modeling languages such as a UML class diagram 7. In methods that use a domain model a CWP would be a key part of it. Figure 5 shows the class and state diagrams of the CWP for the proof-of-technology study.

The Subject System
The interactive system selected for model checking was Priority Contact for doctor-patient communication on test results and treatment plans for chronic disease. When patients have complex conditions doctors need to have real-time discussions with them about test results, diagnoses, and treatment options. Only about 10% of patients in this health system use internet, so phone is the modality of choice. Doctors also use the discussion to determine whether patients who are already dealing with complex treatments and medications will be able to follow the plan. An earlier version of Priority Contact is described in detail in Butler, et al.12.

Priority Contact illustrates the benefits of information technology for telemedicine that integrates desktop with phone technology, and the participation of clinician and patient. It also illustrates the liabilities of systems that involve remote, asynchronous participation that is supported by computing. The Priority Contact system depends on people and computing agents performing their tasks without the visibility that is more available when they are done manually. If any should fail there could be risk to patient health and safety that might go undetected.

The Workflows of Priority Contact
Figure 2 shows a screen shot of the MATHflow12 model of Priority Contact workflows that correspond to four levels of urgency, which were selected by the doctor in a previous task to initiate a contact plan. The workflows were designed to carry out their respective contact plans for:
1. The patient has a life-threatening condition - immediate contact must be made with the patient,
2. A life-changing diagnosis – a real time discussion should take place within a few days to begin major treatment,
3. A routine change to treatment – a telephone appointment should be offered to the patient to take place within fourteen days,
4. No change in treatment is required- the current plan should continue so a discussion appointment is optional to informing the patient of the test results.

MATHflow uses standard BPMN shapes to model the workflows of the four level of urgency with flows (arrows), decision gates (diamonds), tasks (plain rectangles) and sub-processes (rectangles with arrow head and cross at the bottom.

351
As shown in figure 3, sub-processes can, in turn, be opened to contain workflows of the same shapes. Figure 3 shows the contents of the sub-process Make Phone Clinic Appointment P3 that are displayed when it is opened. In addition, the workflow has swim lanes for graphically representing the task responsibilities of Patient and of Priority Contact as they interact to schedule a date and time for a telephone appointment for the patient and the doctor. The performer of a task is also recorded as one of its properties.
Figure 3: Modeling Human and Computer Interaction

Figure 4: Modeling the Use and Change of Information Resources
Figure 4 shows how the use and change of information is modeled as a property of the task PC writes timeDate to doctor’s schedule P3. The editor on the left is to record the information attributes that are used by the task, and the information object where it was accessed, e.g., patientName was accessed in the object Contact Plan. On the right a similar editor records any attribute whose value was changed and the destination object. In this example the task resulted in a value for confirmedAppointmentDateTime being entered to the Physician schedule object.

The MATHflow language treats information as a resource that is used or changed in tasks. In this manner any type of agent that performs a task, whether human or machine, can use information or change its value. This feature of MATHflow allows tasks to change the values of attributes that define the states of a CWP, regardless of whether they are performed by human or machine. This is a key principle for model checking on interactive systems whose workflows have both human and machine performers. The use and change of information in tasks is automatically recorded in MATHflow’s information dictionary. As a MATHflow model is incrementally developed the dictionary stores the associations among tasks, information attributes, values, and the objects where information is accessed.

The Conceptual Work Product of Priority Contact
As shown in figure 5 the CWP of Priority Contact is a Contact Plan represented with two diagrams. At the top the Contact Plan object is modeled as a UML class diagram. The bottom diagram is a UML state diagram.

Figure 5: Priority Contact’s Conceptual Work Product
Together, they are sufficient to specify the CWP and its states that the workflow must accomplish. The specification is independent of any given workflow, technology, or even cognitive strategy. Thus it can be used to verify other versions of the system that make the claim of satisfying the same requirements.

The Contact Plan is made up of several objects. At the center is a Conversation that is needed between Doctor and Patient. The Patient has Disease. The Doctor has Treatment Plan based on the Test Report. The Conversation is about the Treatment Plan. The model includes not only key attributes that define part of the actual state of the contact plan such as priority, launchTime, and resolveTime, but also doctor information, patient information, disease, treatment plan, etc. that is necessary information to accomplish the Contact Plan. All of this auxiliary information is read-only, and does not distinguish the actual state of the CWP at any given point in time and as such that information, with its various relationships to other information, can be abstracted in the verification model.

The states in the diagram at the bottom of figure 5 are defined by rules that use the key attributes. For example, the Contact Plan is in the Launched state when the attributes launchDate and launchTime have non-null values, but all other key attributes are still null. The Contact Plan can reach the Resolved state by either Conversation in progress for priorities 1-2, or Appointment scheduled for priorities 3-4. A Contact Plan may reach No longer needed if the patient somehow is no longer in MyCare of the Doctor.

**Model Checking**

The use of CWP for verifying interactive HIT systems begins by modeling the interactions of the clinician, patients, and Priority Contact as workflows in the MATHflow tool. The state diagram in the CWP is the actual specification for the interactive HIT. It defines the legal evolutions of the CWP from its initial state to its allowed final state. Any workflow must follow these legal evolutions when updating the state of the CWP. Model checking then follows every possible path in the workflow looking for bad sequences that do not reach one of the satisfactory sequences of the states that are required in the CWP specification. Sequences that violate the specification are considered unsafe because the planned progression of care does not happen, and it may go unnoticed. The rest of this section better defines model checking and describes in more detail the results of model checking the Priority Contact system.

Model checking works by constructing an exhaustive proof to show that a transition system implements a specification. Modeling any system requires the definition of all events in the system; these events are sometimes referred to as atomic propositions. A model produces a set of sequences of atomic propositions that represent the behavior of the system. Typically the model is described in some high-level language, and the semantics of that language yields sequences of atomic propositions that represent the language of the model as shown in the Venn diagram in Figure 6.

![Figure 6: Venn diagram illustrating model checking where the universe is sequences of atomic propositions in the model.](image)

The specification is also a language over atomic propositions that precisely describes sequences of interest. This language is usually presented in logic \cite{LTL, CTL}, and that logic describes sequences of atomic propositions that represent the correct language for the system. The inversion of this language creates a language of bad sequences that are not allowed by the specification. In the Venn diagram, this is the region labeled Universe minus Specification.

Model checking is the process of proving that the intersection of the language defined by the model and the language defined by the inverse of the specification is empty: no words are common to the two languages. If such is
not the case, then model checking provides a counter-example: a sequence produced by the model but not allowed by the specification.

The use of CWP for verifying interactive HIT systems is straightforward conceptually. The interactions of clinician, patient, and Priority Contact are modeled as a workflow in the MATHflow tool. The CWP is the specification. The atomic propositions for the language of the model and specification are the state labels in the CWP state diagram. For the Priority Contact model, these are: Launched, Conversation in Progress, Appointment Scheduled, Resolved, and No longer needed. The workflow model evolves the CWP from the initial Launched state and thus produces sequences of atomic propositions. These sequences are the language of the model. Any sequence from the initial state produced on any path in the workflow is part of that language.

The specification contains those sequences allowed by the state diagram in the CWP that start in the Launched state and end in the No longer needed state and only follow transitions defined in the state diagram. Sequences not in the language of the specification represent bad sentences that the model must never produce. For the priority contact example, bad sequences are those that do not end in the No longer needed state or those that make illegal transitions such as moving from the Launched state directly to the Resolved state.

Model checking follows every possible path in the workflow looking for bad sequences. If such a sentence exists, then the language generated by the model is not contained within the language defined by the specification, and the discovered bad sentence is reported as a violation. In general, model checking does not enumerate all bad sequences (if any exist) as only one is required to prove the relationship between the language of the model and the language of the specification.

The SPIN model checker is used in this work. The translation of the CWP and MATHflow model to the SPIN input language is not explained here but there is a fairly direct mapping from MATHflow tasks to processes in Promela. Most of the complexity in the translation is in sequencing and synchronizing the processes. The output from SPIN when no error is found is a coverage summary of the input model that indicates parts of the model that are not activated in the model checking. This inactivation is a result of not providing sufficient input to the model. For example, in the Priority Contact if a P4 no change lab result is never generated, then that portion of the model is not explored in model checking and is reported as uncovered. The output form SPIN when an error is found is a trace through the input file and a trail file that SPIN is able to replay in simulation mode for debugging purposes. If desired, then SPIN can be configured to return all errors and not just the first discovered error.

The rest of this section is devoted to the results of model checking the Priority Contact example. The SPIN model checker discovered errors in the workflows of all of the priorities. To bring this result into context, only one of the errors was seeded purposely by the modelers. The other workflows were believed to be correct.

Figure 2 is the top-level workflow of the different levels of priority in the Priority Contact system. Using this figure as a reference, a brief description of the discovered errors follows:

- **P1 Life Threatening**: in the PC carry out contact plan P1 process a gateway had no outgoing edge and was essentially disconnected from the rest of the model. As a result, any path leading to that gateway left the CWP in an invalid end state. The error was corrected by connecting the gateway to the remaining flows.
- **P2 Life Changing**: this error was seeded by the modelers. In the Doctor inform patient of results process action to move the CWP into the No longer needed state was removed by the modelers.
- **P3 routine change**: the modelers had included a Preferred mode of Communication gateway where the user is able to designate Mail, Auto-call, or MyHealthEvet. In the cases of Mail and MyHeathEvet, the tasks failed to move the CWP out of the Launched state. The error was corrected by removing the gateway as these options were hold-overs from a prior design that the designers had failed to remove.
- **P4 no change**: aside from the legacy gateway carried over from that prior design that was identical to the P3 routine change error, this workflow failed to move the CWP out of the Launched state. Neither the Make phone clinic appointment P4 nor the Discuss no change processes recorded the scheduled appointment, conversation, or resolution of the priority contact on any path. The error was corrected by modifying the tasks in Make phone clinic appointment P4 and Discuss no change. Tasks in these processes now change the state of the CWP indicating when the appointment is confirmed, the conversation takes place, and the doctor marks the contact as resolved.

The errors, though seemingly trivial, persisted through several reviews of the model, indicating the value of model checking if for nothing more than a sanity check on the connectivity of the model and the basic evolution of the CWP by the workflow.
Conclusion

The meaning of the model checking result is that the MATHflow model of the Priority Contact system implements the CWP under all possible inputs and under all possible ways for the actors to communicate. A faithful implementation of the MATHflow model would be correct relative to the intended work. The more general meaning is that a CWP can serve as a common entity which both clinicians and computers can change, thus allowing model checking technology to evaluate workflows that have both human-performed tasks and machine-preformed functions with vastly different capabilities in the same model. The MATHflow model and the CWP model could readily be translated into the input needed to apply established model checking tools. Extending model-checking to interactive health IT systems has great potential to advance HIT design and address safety in a powerful, formal method. To our knowledge no other approach can formally evaluate how well HIT is integrated with the fundamentally important manual activities of care. Before a system is actually built model checking can either prove that an interactive system can do the job it is supposed to do, or it identifies failures must be addressed.

Model checking proves a transition system implements a specification. To date, much of the research with model checking in health care has focused on formalizing workflows and proving temporal properties on workflows. The approach in this paper shifts focus to the work intended to be accomplished by a workflow. It uses model checking to prove that a workflow is capable to accomplish the work product that is specified in the CWP. Also, unlike prior work, this approach to model checking tries to use the CWP state diagram directly to prove the correctness of the system. This approach is in direct contrast to where the system specification is expressed in terms of formal logic.

Health IT is less mature than other established domains for system design. Absent a clear CWP specification and a technique for verifying at least partial algorithm correctness for producing a CWP, there is no basis to evaluate whether the workflow of a proposed HIT system is capable to accomplish the CWP. Further, it is not meaningful to compare systems on safety-related qualities such as usability if they have not been verified to produce equivalent work products. Consequently, HIT development may struggle with fundamental design decisions, such as how to achieve safe care improvements via appropriate allocation of functionality among clinical personnel and computing. Conversely, it is far more meaningful to compare workflows that have been verified as comparable for a variety of qualities such as reliability, usability, or efficiency, thus giving designers great latitude to find better solutions. Further, definitions of the checks could be instrumented as part of the HIT software to continue monitoring safety-related conditions after a verified system has been deployed. These capabilities should be important steps towards realizing the great potential of HIT.

Future Work

There are many directions opened up by the capability to verify socio-technical systems for healthcare. The new method first evaluates how the system will behave under idealized conditions, e.g., networks do not fail, and people show up for work on-time. We aim to investigate how the assumptions of the idealized system can then be relaxed to explore fault tolerance, and support designing to eliminate or mitigate the risks.

There are three critical pieces of future work related to the model checking step, itself: automation, scaling to large systems, results presentation, and workload analysis. The first step automates the process of extracting a Promela model from the MATHflow and CWP. It is critical for case studies on complex HIT systems. The second step characterizes the model checking on larger systems to understand its limits, and explores various techniques to mitigate state explosions including abstraction. The SPIN model checker typically scales to systems with millions of states, and it is hoped, but not yet known, that it is sufficient to verify interesting HIT processes. The third step relates directly to the usability of the model checking results. Any verification counter-example (i.e., a path that does not accomplish the work), must be mapped back into the MATHflow model and illustrated in MATHsim for the user to diagnose. We also plan to investigate how ontology modeling technology, with automated inferencing, can assist formally defining and scoping key CWP for clinical healthcare. These ontology models could provide a reusable inventory of key conceptual work products of clinical care to support health IT developers.

Employing complex polyhierarchical ontologies and promoting interoperability of i2b2 data systems

James Richard Campbell MD, Walter Scott Campbell PhD, Hubert Hickman MS, Jay Pedersen MS, James McClay MD

1University of Nebraska Medical Center, Omaha, NE; 2Nebraska Medicine, Omaha, NE, 3University of Nebraska at Omaha, Omaha, NE

Abstract

I2b2 is in widespread use for managing research data warehouses. It employs reference ontologies as a record index and supports searching for aggregate cases using a pattern match operator on ASCII strings representing the node traversal from root to concept (PATHs). This creates complexities in dissemination and deployment for large polyhierarchical ontologies such as SNOMED CT. We hypothesized that an alternative approach employing transitive closure tables (TC) could lead to more accurate, efficient and interoperable search tools for i2b2. We evaluated search speed, accuracy and interoperability of queries employing each approach. We found both TC-based and PATH-based queries to produce accurate results. However, we observed that TC-based queries involving concepts included in large numbers of paths ran substantially faster than PATH-based queries for the same concept. Oracle query plan resource estimates differed by one to three orders of magnitude for these queries. We conclude that a simplification of dissemination tools for SNOMED CT and revision in the metadata build for i2b2 can effectively employ SNOMED CT with increased efficiency and comparable accuracy. Use of transitive closure tables in metadata can promote network query interoperability.

Introduction

Slowly and with little fanfare, reference terminologies and advanced ontologies supporting structured clinical data are reorganizing and enhancing electronic health records (EHR) and providing advanced data structures in support of clinical decision making. This has been accelerated in the US by coding requirements built into the Meaningful Use program by the Office of the National Coordinator for Health Information Technology. EHR vendors are struggling to understand and appropriately deploy these technologies and the research and public health communities have scant understanding of their importance or technical underpinnings.

With the advent of ambitious programs to develop and support large clinical research networks and the appearance of tools for big data bases, program administrators have little to guide them in the effective deployment of ontologies within data management systems. Arguably one of the greater challenges is SNOMED CT (SNCT) which is the most comprehensive healthcare ontology with a concept space of more than 302,000 elements. This large ontology can be difficult to effectively integrate into research data management tools. The September 2014 release of US edition of SNOMED CT is published as UMLS data sets of 3.05 Gbytes. The release format is an RF2 dataset specified by the IHTSDO but does not include any software or detailed guidance for best practice deployment into a system such as i2b2.

SNCT employs a concept model enforced by a description logic classifier which specifies the relationships and attributes to be used for concept definition in each SNCT domain. SNCT employs polyhierarchy (Definition: a hierarchically organized set in which a node may have more than one parent) in the ontology which means that the larger domains such as 404684003|Clinical finding (finding)| and 71388002|Procedure (procedure)| may have hierarchies of 30 generations in depth and many supertype concepts (Definition: X is the supertype of Y if a directed path of IS_A relationships can be traced from X to Y). Counting the possible paths from the root to a leaf concept, required for i2b2 metadata build, can be daunting since polyhierarchy expands the combinatorial possibilities. In the 2014 release of the US edition of SNCT there are up to 7802 paths (312411001|Carcinoma of the hepatic flexure (disorder)|) and an average of 11.1 paths per concept.

A research data management toolset in common use is i2b2. i2b2 software was first developed in 2004 when state of the art for terminology standards was ICD-9-CM and CPT-4. In contrast to SNCT, both are monohierarchies of modest size. (Definition: A hierarchically organized set in which any node may have at most one parent) i2b2 employs a star schema information model with four reference dimensions and a central fact table. i2b2 supports aggregation or subsumption queries (Definition: a subsumption query for concept X seeks to enumerate all instances from the fact table using the SQL pattern

359
match operator (LIKE) and an exhaustive set of PATHs from root concept to the node. For example, one possible path for the SNCT concept 128192002|Chronic disease of cardiovascular system (disorder)| is 404684003|64572001|276243003|128292002. Figure 1 shows the SNCT hierarchy for this concept and the sequence of nodes in path number one which illustrate the path computation. In total for this concept there are 4 possible paths.

Transforming the NLM release of the US edition of SNOMED CT into i2b2 metadata is difficult and time consuming, resulting in files of 4.984 Gbytes; these are troublesome to manage and share between collaborators seeking to standardize their research data. Distribution of i2b2 metadata files from the National Center for BioOntology using web services is available for SNOMED but reported to be seldom employed.

Importantly in this era of evolving national research networks, the i2b2 SQL query generated by the software is unique to the path selected by the user. It is only interoperable with other sites if their metadata deployment is exactly identical. To its credit, i2b2 manages such queries as efficiently as was considered possible in the age of ICD-9-CM.

Figure 1. SNOMED CT path computation

Extending previous work of Harris¹¹, we hypothesized that deployment of a revised i2b2 search algorithm for SNOMED CT employing simple transitive closure tables for subsumption queries would be faster and as accurate as conventional i2b2 methods. (Definition: A transitive closure set for any concept X in a IS_A hierarchy is the set of nodes which includes X and any node Y which has a path to X by following one or more directed ISA relationships¹² ) We further expected that a compact piece of software could install the SNOMED CT metadata using only NLM data sets. We believed that i2b2 queries employing transitive closure would be interoperable across i2b2 installations with metadata build which could be tailored for local needs.

Methods

We installed i2b2 version 1.7 in our research data warehouse on a Dell Poweredge R820 server with 16 cores and 128GB RAM; 2X744GB SAS solid state drives; 14 TB SAS 10K drives; supporting Oracle 11g.

We obtained the September 2014 RF2 release of SNOMED CT, US edition, from the UMLS Terminology Services site¹³ of the National Library of Medicine. We extracted the set of all active SNOMED CT concepts, relationships and descriptions from the snapshot version following the file documentation provided in the Technical Implementation Guide⁹. All concepts pertinent to this release were identified with moduleID values of 900000000000207008 and 900000000000012004 (International release) and 731000124108 (US-edition concept)¹⁴. We extracted the hierarchical (IS_A) relationships from the release files and developed a Python program that used those to prepare i2b2 metadata. First we identified the top concept for all SNCT hierarchies as first order subtypes of 38875005|SNOMED CT Concept|. We then calculated i2b2 metadata paths for SNCT employing an algorithm which is a modification of the standard depth-first search algorithm for graphs¹⁵. From the path search the program further prepared a transitive closure table for all of SNCT. A portion of the table is displayed in figure 2. The i2b2 metadata we prepared was employed in our i2b2 client as two versions: one using a conventional i2b2 PATH search and the Oracle ‘LIKE’ operator for computation of subsumption, and a second using a Transitive closure (TC) table and the ‘~’ operator. Figure 3 compares the metadata tables from i2b2 for the two search protocols. We created the
two versions of metadata to prepare the test environment for our research. i2b2 allows development for integration of ontologies. Historically, while most i2b2 metadata sets have been based upon concept paths, the flexibility of

![Fragment of transitive closure table](image)

i2b2 allows the development of other types of metadata such as dimension based metadata. Integration of the transitive-closure metadata table allows the i2b2 search engine to replace path-based calculation of subsumption with simple parent-child based subsumption using the TC table. Figure 3 shows the important columns from the two examples of i2b2 metadata. The first examples is transitive closure metadata, and the final column shows the traditional path based metadata. Note that we have created a concept_dimension_2 table analogous to concept_dimension that we use to isolate our testing with the traditional i2b2 style of metadata.

![Metadata attributes](image)

To compare accuracy and efficiency of the transitive closure methods, we developed a set of queries to be run using PATH-based logic and again using TC-based logic. The order in which the query logic was employed for each testing pair was randomized using a flip of the coin for each concept queried. The scope and complexity of each concept query varied from high-level concept such as 118234003|Findings by site(finding)| to mid-level concepts (128238001|Chronic heart disease (disorder)|) and low-level concepts (93030006|Congenital absence of spleen (disorder)|). We tested complex query performance by running queries that involved set calculations and disjoinoweeness, such as “count all patients with a chronic disease but not chronic cardiovascular disease”. We obtained database query resource requirements assessing query economy for each query using the “explain plan” SQL tool which provides an Oracle predicted relative resource value.

We further constructed an independent graph database and instantiated it with the fully classified SNCT model prepared from the same release files. We developed software to create the transitive closure table from the graph
database for validation of the i2b2 build. We compared the graph database transitive closure table to an instance developed with IHTSDO documented methods and validated the content of SNOMED CT. We copied all observation fact data from i2b2 to the graph database and reproduced the anonymized patient and SNOMED CT problem coding as an independent validation set. We then used the graph database to reproduce the concept queries that we employed for testing of TC and PATH query function and compared patient query sets for accuracy and reproducibility.

**Results**

The metadata implementation we developed employs the 20140901 RF2 snapshot release of SNOMED CT which is 503 MB of uncompressed terminology. The Python code produced a transitive closure table of 181 MB and a metadata set of 7.45 million rows at 4.984 GB. The metadata is complex due to SNOMED CT polyhierarchy and has from 1 to 7802 paths per concept. 16865 concepts of the 302,000 in the release have >=100 paths, most from 404684003|Clinical finding (finding)| hierarchy.

Table 1 summarizes the results of our controlled experiments with query execution. All queries retrieved identical patient sets regardless of query method, PATH-based or TC-based. We validated patient counts independently with queries of the graph database. We observed that subsumption query times for high-level concepts frequently ranged from 50% to 200% longer using the PATH-based approach. Query A in table 1 summarizes results for 404684003|Clinical finding (finding)| and query B 118234003|Finding by site (finding)| which are representative of these differences. Oracle relative resource estimates differed by up to three orders of magnitude in favor of the TC-based approach for these queries. We observed that query times involving concepts deeper in the SNOMED CT hierarchy were comparable between methods and differences between Oracle relative resource differences were negligible. Examples of these observations are reported in cases C, D and F. Queries incorporating disjunction for mid-level concepts also ran equally efficiently between methods (Table 1, query E). Surprisingly, we noted run time variability in PATH-based queries depending on browsing path chosen by the user. For example, see queries G and H in Table 1. In no case did PATH-based queries run faster that TC-based queries and summary statistics favored transitive closure procedures in an unpredictable manner that made non-biased quantitative assessment impractical.

Figure 4 recounts SQL generated by the i2b2 query engine to retrieve observation facts for query instances G and H from table 1. All three examples are searching for subsumed concepts of 13645005|Chronic obstructive lung disease (disorder)|. Queries 4a and 4b are both from path-based queries for this concept set but were generated when the user chose different navigation paths from the root to the concept during browsing for the concept in the SNOMED CT hierarchy. Query 4c is the SQL generated by the i2b2 query engine when employing metadata prepared for transitive closure searches as in figure 3. Note that SQL generated by the two PATH-based queries differs in the PATH segments chosen for searching.

![Figure 4. i2b2 SQL code fragments querying for 13645005|Chronic obstructive lung disease (disorder)| and 3b are path-based subsumption queries; 3c transitive closure-based subsumption query](image)
Discussion

We have documented our SNCT metadata build program for i2b2 and have published the code, transitive closure table and SNCT snapshot for PCORI sites which are using i2b2. Due to the relative simplicity of metadata creation from a transitive closure table for the use case of subsumption queries, we have discussed the publication of a transitive closure table for US Edition of SNOMED CT with NLM staff.

Deployment of the SNOMEDCT transitive closure tables allows construction of subsumption-complete subsets of SNOMEDCT. That is, with the subsumption logic embodied in the transitive closure table instead of explicit in enumeration of concept paths, subsets both in breadth and depth of the SNOMED CT ontology can be built. The build will find all subtype concept instances in the database, regardless of path build in the browser metadata set.

Requirements of the i2b2 metadata build are a real impediment to deployment of advanced ontologies such as SNOMED CT due to complexity and file size. Searches employing PATH-based metadata do not generate unique SQL statements in the setting of polyhierarchies and are a risk to the interoperability for queries to be shared within.

</table>
a research network. In order to limit the size of metadata files, we had performed earlier experiments building only a limited number of paths for each SNCT concept. We verified that the strategy was untenable and produced erroneous responses to queries as well as dysfunction of the browsing environment. Therefore management of interoperability risk constrains i2b2 metadata since the metadata also supports the data browsing environment. By eliminating the need for a Concept_dimension table in the CRC cell and removing PATH data from the SQL query, a transitive closure metadata build is a step towards a flexible browsing interface, reduced i2b2 maintenance for terminology updates and improved interoperability of network query management.

We expect, but have not yet tested our results for consistency of i2b2 function on other SQL supported databases; namely SQL Server and Postgresql. We will be deploying our SNOMEDCT metadata and transitive closure table on each platform.

We conclude that the set of cases returned by the PATH and TC-based approaches were identical for each query. We confirmed the accuracy of these query results using an independent graph database representation of the data and different programmatic search engine. We included a complete and comprehensive enumeration of IS_A pathways in our build of i2b2 metadata because of the requirements of the i2b2 browsing software. Regardless of the specific path chosen by the user from the top-level concept, the query responses were identical for PATH and TC queries.

We consistently observed that speed and programmatic efficiency was as good or better with TC-based queries compared to conventional i2b2 PATH-based searches. As a puzzling observation, we found PATH-based queries of polyhierarchical concept data introduced unanticipated variation in query time response. While ASCII string length and the number of paths involving the target concept seemed to influence efficiency, we were unable to develop a quantitative model of query performance.

Conclusions

Deploying complex polyhierarchical ontologies in i2b2 can be a daunting task. We have documented and published one approach which has the virtues of employment of a US Meaningful Use2 standard ontology, modest file size and freely available software. Metadata maintenance workload is diminished since metadata tables are more compact. Extending the work of Harris11, we have confirmed that modifying i2b2 metadata build to employ transitive closure tables for support of subsumption queries leads to accurate results with retrieval efficiency as good or better than the current convention. SQL queries built from these modifications are devoid of browsing ontology references and are semantically parsimonious, promoting query interoperability.

Abstract

Tele-education systems are increasingly being utilized in medical education worldwide. Due to limited human resources in healthcare in low and middle-income countries, developing online systems that are accessible to medical trainees in underserved areas potentially represents a highly efficient and effective method of improving the quality of the health care workforce. We developed, implemented, and evaluated an interactive web-based tele-education system (based on internationally accepted, image-based guidelines) for the diagnosis of retinopathy of prematurity among ophthalmologists-in-training in Brazil, Mexico, and the Philippines. We demonstrate that participation in this tele-education program improved diagnostic accuracy and reliability, and was preferred to standard pedagogical methods. This system may be employed not only in training, but also in international certification programs, and the process may be generalizable to other image-based specialties, such as dermatology and radiology.

Introduction

Medical education has undergone significant changes over the past decade with the integration of technology and online learning increasingly replacing physical lectures.\textsuperscript{1-5} In fact, so-called massive open online courses (MOOCs) are in some cases changing the entire paradigm of higher education away from on-site classroom learning.\textsuperscript{6-9} These online curricula have several advantages including standardization of content across large audiences, the ability to be utilized remotely, lower cost, and decreased dependence on local expert human resources for teaching.\textsuperscript{7,10} While in wealthier countries, this may change the form of knowledge delivery, in countries with less-developed healthcare and educational infrastructures, access to online tele-educational resources can dramatically change not only the form, but the quality and quantity of the educational content available to local trainees. Most importantly, tele-education systems allow for access to high quality education without an immediate need for an increase in local expert human resources, which may be non-existent or otherwise too busy to devote time to education.\textsuperscript{11,12} Therefore, the pedagogical argument for development of international tele-education systems is strongest for those specialties where the human resources are the most limited and/or the content is the most challenging to teach.

Retinopathy of prematurity (ROP) is a leading cause of childhood blindness worldwide.\textsuperscript{13} ROP care is clinically challenging and resource intensive. In the United States, despite a relative abundance of ophthalmologists and neonatologists compared to most of the world, there remain challenges to meeting the needs of ROP education as well as clinical care.\textsuperscript{14-16} Worldwide, this paucity of trained ROP providers is even more extreme in middle-income countries, where advancements in neonatal survival for preterm babies are resulting in increasing numbers of infants developing ROP.\textsuperscript{13} Moreover, accurate diagnosis of ROP can be challenging and many studies have demonstrated poor inter-examiner reliability, especially among providers with less experience, which raises serious concerns about the quality of care in medically underserved areas.\textsuperscript{14,16,17}

Tele-education can improve the exposure to and standardization of ROP education, and has potential to improve diagnostic competency of ophthalmology trainees worldwide. We developed an interactive tele-education system for ROP education and implemented this system at ophthalmology training programs in Brazil, the Philippines and...
Mexico. The purpose of this project was to determine the efficacy and trainee satisfaction of a remotely implemented ROP tele-education system. This system has potential to improve the quality and widespread delivery of ROP education and therefore indirectly (but significantly) improve the quality of medical care particularly in medically underserved areas throughout the world. Furthermore, this study demonstrates validation of principles that may be generalizable to other medical specialties, particularly ones that rely heavily on image-based diagnosis such as dermatology and radiology.

Study Domain

ROP is an ocular disease that develops in low birth weight and low gestational age infants, affecting approximately 14,000-16000 children in the United States per year.\textsuperscript{18} Diagnosis requires accurate recognition of disease, which has been classified by international guidelines established to triage these infants into one of several categories: no ROP, mild ROP, moderate ROP, and severe (treatment-requiring) ROP.\textsuperscript{19} Approximately 90\% of infants who develop ROP will have only mild or moderate disease and will require follow-up examinations every 1-2 weeks for the first few months of life.\textsuperscript{18,20} However, approximately 10\% of patients will progress to severe ROP. For these latter infants, treatment with laser photocoagulation or intraocular injection of pharmacological agents has been shown to successfully prevent blindness in most cases.\textsuperscript{18,20} Therefore, diagnostic accuracy of ROP that is high risk for requiring treatment is critical for preventing pediatric blindness.

Methods

The Weill Cornell Medical College (WCMC) and the Oregon Health & Science University (OHSU) Institutional Review Boards approved all aspects of the use and analysis of retinal images and educational material used in this study. Administration and analysis of the tele-education system was also reviewed by the WCMC Institutional Review Board, and was granted an exemption because it was considered research in an established or commonly accepted educational setting involving normal educational practices such as research on the effectiveness of instructional techniques, curricula, and instructional strategies. This study was conducted in adherence all federal and state laws and was in accordance with Health Insurance Portability and Accountability Act (HIPAA) guidelines.

Development of the Retinopathy of Prematurity Tele-education system

A secure web-based tele-education system was developed utilizing a repository of over 15,000 images captured from routine ROP exams. The system was coded in C# on the ASP.NET platform (Microsoft; Redmond, WA), and employed a SQL Server database. To facilitate software development and compatibility across different web browsers, the system was developed using an open source JavaScript wrapper (jQuery; Mozilla; Mountain View, CA). Modules were developed in both English and Portuguese.

Tele-education system content and procedures

Figure 1 demonstrates the procedure for the tele-education system, which consisted of four unique sections: (1) Pre-test examination; (2) ROP tutorial; (3) ROP training chapters; (4) Post-test examination. Clinical cases were presented in the Pre-test examination, ROP training chapters, and the Post-test examination. Each case included relevant clinical demographics and retinal images of both eyes. (Figure 1A). Trainees were required to enter a diagnosis for all image-based characteristics of ROP as defined by an internationally standardized classification system: plus disease (no, pre-plus, plus), zone (I, II, III), stage (1-5), category (no ROP, mild ROP, moderate ROP, severe treatment-requiring ROP), and aggressive posterior-ROP (APROP) for each individual eye. For the purposes of this study, the primary outcome measure was the overall disease category: presence of mild-or-worse, moderate-or-worse, or severe (treatment requiring) ROP.

Sections 1 and 4: Pre-test / Post-test. At baseline, and following the completion of the ROP training chapters each trainee completed a set of 20 clinical cases with various degrees of ROP. 16/20 cases (80\%) were unique and 4 (20\%) were repeated to measure intra-grader reliability. Completed cases could be reviewed but not changed during the testing and no feedback was provided.

Section 2: ROP Tutorial. Following the pre-test examination, trainees completed a tutorial on ROP diagnosis and management designed by the co-authors (RVPC, KEJ, SO, MFC). The ROP tutorial included didactic information on the different classifications of ROP and pertinent management considerations (treatment, follow-up time). When trainees were in between different chapters, the ROP tutorial was available as a reference for clarification, but the
tutorial was not available while trainees were in the pre-test or post-test examinations, or within a ROP training chapter.

Section 3: ROP Training Chapters. After completing the ROP tutorial, trainees were asked to complete five training chapters, each consisting of five clinical cases. Within each training chapter, trainees were given immediate feedback on their accuracy (Figure 1B) and targeted supplemental educational material was provided for any incorrect answers in four ways (Figure 1C): (1) Review of the image for which an incorrect response was provided; (2) Annotated images from the case that highlights the specific pathology; (3) Additional annotated images selected by the program from the database of validated images of other cases that highlight the specific pathology and; (4) Images that highlight the specific pathology corresponding to the (incorrect) chosen response. After reviewing the automated feedback based on their specific responses, trainees could then proceed to the next clinical case within the training chapter. After completing each chapter, trainees had the option to: (1) Proceed to the next chapter or section; (2) Review the ROP tutorial; (3) Review their responses and feedback from previous training chapters.

![Figure 1](image-url)

**Figure 1.** ROP Tele-education system procedures. (A) demonstrates progression through the course (pre-test examination, ROP tutorial, training chapters, and post-test examination), and displays a sample clinical case. In the training chapters, following the selected diagnosis, trainees were provided immediate feedback (B) and targeted supplemental tutorial and review (C).
Consensus Reference Standard Diagnosis

To ensure accuracy in the educational content, particularly because of potential variability in diagnosis among physicians, a reference standard ROP diagnosis was determined for each case by consensus of three experts and the clinical diagnosis. This was done using previously-described methods: (1) The clinical diagnosis (based on complete ophthalmic exam by an experienced examiner) was recorded; (2) Each set of retinal images was interpreted by 3 experienced readers using a web-based system; (3) The image-based diagnosis that was selected by the majority of image readers was then compared to the clinical diagnosis. When these two diagnoses are the same, it was defined as the consensus reference standard diagnosis. When the diagnoses are different, all of the data were reviewed by two of the investigators (RVPC, MFC) along with two study coordinators (KEJ, SO), and a consensus reference standard was determined. This consensus reference standard diagnosis was then used for the purposes of this current study.

Study Population

Ophthalmologists in training were recruited by the co-authors (KEJ, RVPC, RA, CVV, MAMC) from training programs in Brazil, Mexico, and the Philippines. Ophthalmology trainees in all years were allowed to participate in the ROP tele-education system. At one program, a control group was provided the pre-test examination, followed by the post-test examination to be taken at least one month after the pre-test examination (to prevent immediate recall), but was not given access to the ROP tutorial or ROP training chapters. At this program, trainees were randomized 1:1 to participate in the program as part of the control group or take the tele-education system as indicated in Figure 1.

Survey

A survey was designed using a publicly available service (http://www.SurveyMonkey.com). Six questions were adapted from existing psychometric instruments to measure trainees’ attitudes using a 5-point Likert-type scale (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, 5=strongly agree); one additional question allowed for free-text comments. Questions were reviewed by the authors for face validity and content validity and modified until all authors were satisfied with the survey instrument. Of the six questions, two assessed the trainees’ perception of their understanding of the diagnosis of ROP, three assessed the trainees’ attitudes toward preferred learning environment, and one assessed the trainees’ opinion of ease of use of the ROP tele-education system. All participants were invited to complete the survey.

Statistical Analysis

The main outcome measure was the post-ROP tele-education program sensitivity (compared to the pre-program sensitivity) of diagnosing any ROP (mild-or-worse ROP). The sensitivity and specificity of each disease category (mild-or-worse, moderate-or-worse, and severe) was measured before and after participation in the program. Sensitivities and specificities were compared using the paired t-test for each program and for all trainees as a single cohort, and by program, and statistical significance was considered to be a 2-sided P value <.05. For the training program with a control group, a secondary outcome measure included change in sensitivity of “active” education vs. control for each disease category. Data were analyzed using the R statistical software platform. Sensitivity and specificity values were calculated using the caret package. Based on the 4 cases that were repeated in both the pre-test and post-test examination, intra-grader reliability was evaluated using the kappa (k) statistic for chance-adjusted agreement in diagnosis. Cohen’s Kappa values were calculated using the irr package, and figures were generated using the ggplot2 package. A well-known scale was used for interpretation of results: 0 to 0.20, slight agreement; 0.21 to 0.40, fair agreement; 0.41 to 0.60, moderate agreement; 0.61 to 0.80, substantial agreement; and 0.81 to 1.00, almost-perfect agreement. Descriptive statistics were used to summarize the trainees’ responses to the post-ROP tele-education program web-based survey. The non-parametric Wilcoxon signed-rank test was used to compare the trainees’ pre- and post-ROP tele-education program perception of their understanding of the diagnosis of ROP.

Results

Characteristics of Study Population

Table 1 summarizes key characteristics of the three training programs and study participants. 92 ophthalmologists-in-training were provided access to the ROP tele-education program among the three programs, and 8 completed the program: 27 at program 1 (with 26 randomized to control), 43 at program 2, and 11 at program 3. None of the training programs involved have a formal ROP curriculum to assess clinical competency of graduates, but all
programs had some exposure to ROP, and trainees were familiar with interpreting wide-angle retinal images such as those used in the program.

Accuracy of ROP Diagnosis among Participants and Controls in the ROP Tele-education Program

Table 2 summarizes the pre- and post-ROP education program sensitivity and specificity for the diagnosis of ROP. The pre-test sensitivity of detecting mild-or-worse ROP was 81% (SE), which improved to 93% (SE) following the program, P < 0.001. There were statistically significant increases in sensitivity and specificity in all diagnostic categories. In subgroup analysis by program, these trends persisted with increases in sensitivity and specificity in each case.

Intra-Grader Agreement among Participants in the ROP Tele-education Program

Table 4 demonstrates the kappa statistics for intra-grader agreement among participants in the pre-test and post-test examinations of the ROP tele-education program. For the detection of mild-or-worse ROP among all participants (N=81), the kappa increased from moderate (0.57) to substantial agreement (0.8), with similar trends in every program and disease category. In the control group (N=26), the kappa also increased from 0.59 to 0.75, demonstrating improved intra-grader agreement with repeated testing over time, even without access to ROP tele-education program. 24 / 26 (92%) of control trainees waited the requested month between the pre-test and post-test examinations.

ROP, retinopathy of prematurity.

POST-RETINOPATHY OF PREMATURITY TELE-EDUCATION PROGRAM SURVEY OF TRAINEES

31 of the 81 trainees (38%) who completed the ROP tele-education program also completed the post-program survey. Figure 2 shows the results of this survey. With a maximum score of 5 for each question, the average score for each question was calculated. The average score for question 1 (adequate understanding of ROP before the tele-education system) was 2.4/5, as only 5 (16%) of the respondents agreed or strongly agreed that they had an adequate understanding of ROP diagnosis before taking the ROP tele-education program. Following the program, the respondents’ score averaged 4.3/5 suggesting that they felt their knowledge significant improved through the program (signed-rank test; P<.01). 31 / 31 (100%) of the respondents agreed or strongly agreed that they had an adequate understanding of the diagnosis of ROP after completing the ROP tele-education program. The average score for question 2 (ROP tele-education was easy to use) was 4.2/5 as 29 (94%) of the respondents agreed or strongly agreed that the system was easy to use. 30 (97%) of the respondents agreed that the feedback at the end of cases was helpful (question 3). For question 6 (preference for interactive system over textbook learning), the average
score was 4.2/5 as 29 (94%) respondents agreed or strongly agreed that they learned more effectively with the automatic feedback opposed to textbook learning.

![Image of survey results](image_url)

**Figure 2.** Survey results of trainees who completed the retinopathy of prematurity (ROP) tele-education program (N = 31).

**Discussion**

**Summary of Key Findings**

We report the effective use of a tele-education system for teaching a clinically challenging ophthalmic disease in middle-income countries. We validate the concept that for image-based diagnosis, an internet-based tele-education system can be effective and preferred to more traditional educational models. The key findings from this study are:

1. This ROP tele-education system significantly improved the diagnostic accuracy and reliability of ophthalmology trainees.
2. Participants found the ROP tele-education system easy to use and they felt that they learned more effectively from ROP cases with automatic, targeted error-based feedback compared to a traditional textbook format.

**Implications for Retinopathy of Prematurity Care and Telemedicine**

These results demonstrate that a web-based tele-education system can be effective at improving the diagnostic accuracy for ROP for ophthalmology trainees in Brazil, Mexico, and the Philippines. Following completion of the course, trainees demonstrated 93% sensitivity at detecting mild-or-worse ROP, 71% sensitivity at detecting moderate disease, and 66% sensitivity at identifying severe (treatment-requiring) disease. To put this in perspective, these trainees outperformed a cohort of US pediatric ophthalmology fellows (85%, 53%, and 52% sensitivity for identifying mild, moderate, and severe disease, respectively) who completed ophthalmology training in the United States, but who did not complete this tele-education system. Additionally, participants in the tele-education program demonstrated improved intra-grader reliability of diagnosing ROP from “fair” or “moderate” to “substantial” agreement for all subtypes, including treatment-requiring ROP. These results are particularly significant in the diagnosis of ROP, in which despite the presence of international evidence-based, image-based guidelines, the literature consistently reports poor intra-rater and inter-rater reliability in ROP even among experts. As the routine care delivery model for ROP moves towards the use of telemedicine for screening and referral, the success of any telemedicine program will be dependent on the accuracy and reliability of the graders. Thus, though there remains room for improvement, particularly at recognizing moderate and severe ROP, as a pilot implementation of a tele-education system these results are extremely encouraging.

**Implications for International Tele-Medical Education**

The lack of human resources is perhaps the most critical factor limiting improvements in health care education and delivery in low and middle-income countries. In the US there is approximately one ophthalmologist for every 10,000 persons. In India, the number is closer to 1:100,000, and in most parts of Sub-Saharan Africa, it is less than 1:1,000,000. Compounding the human resource problem, among medical trainees in low and middle-income countries, access to quality medical education remains limited, and the ability to become well trained in the management of a complex disease such as ROP can be difficult. Even in the United States, ROP education has its challenges, as US trainees generally do not feel well qualified to perform ROP care independently without additional training. In middle-income countries where the number of cases of ROP is rising, the current medical education system has not been able to train enough qualified providers to manage emerging epidemic. Thus, a tele-education...
system that can be accessed from anywhere in the world that can demonstrate significant improvement in diagnostic accuracy and reliability has the potential to greatly impact the quality of ROP care, and mitigate the incipient rise in pediatric blindness in these countries. Moreover, these results suggest that a similar model could be used for other medical specialties that rely primarily on image-based diagnosis, such as dermatology, pathology, radiology, and cardiac electrophysiology and echography.

In addition to being utilized to improve diagnostic performance among trainees and practitioners, a similar web-based interactive system could be used to standardize and certify medical specialists for any of these specialties. The development of this web-based training system utilized a novel method for validating the reference diagnosis for each image against which trainees could be evaluated. Compared to traditional examinations with a limited number of testable images, and no intra-test interaction with the test-taker, there is tremendous potential for an interactive web-based system with thousands of validated images not only to assess clinical competency but to improve the accuracy and reliability of participants, and thereby improve the quality of “certified” care providers around the world.

Limitations
There are several limitations that should be mentioned. First, due to small numbers limiting statistical power, we were only able to randomize participants into a control group at one of the three training programs, and we were not able to include a control group based on more traditional pedagogical methods, such as textbook chapters and classroom lectures. Presumably, traditional methods of learning can provide similar results. That said, none of these programs currently have an established curriculum (nor do, for that matter, most US programs), and we have demonstrated that providing remote access to this tele-education system can markedly improve diagnostic performance, exceeding that of US graduates, with limited local effort or resources. Second, in this pilot study, we did not attempt to determine the common diagnostic errors that led to incorrect responses. Third, we are unable to estimate whether a longer program or some modification of this program would perform better, or a shorter program perform equivalently. Fourth, though we did include a Portuguese system for the Brazil group, we relied on the common familiarity with medical English in Mexico and the Philippines. It is possible that these results may not easily translate when multiple translations are required for other countries and languages. We plan to investigate these questions in future studies.

Conclusions
In summary, we demonstrate that participation in this ROP tele-education system can increase diagnostic accuracy and reliability among trainees in Brazil, Mexico, and the Philippines. Program participants found the web-based, interactive system easy to use, and preferable to traditional learning methods. These results provide evidence that tele-education may be an effective modality to improve diagnostic performance in ophthalmologic disease, and particularly in middle-income countries, where there is an emerging epidemic, tele-education may represent a key strategic intervention to improve the quantity and quality of ROP care providers without added burden to existing local human and educational resources. As telemedicine and tele-education approaches to clinical care and education become more mainstream, we believe that these results may be generalizable to other medical specialties which rely on image-based detection of disease using international standards.

Abstract

Drug misuse is a prominent cause of morbidity and mortality in the United States. Recent focus on behavioral and social domains in the electronic health record (EHR) has highlighted the need for comprehensive examination of social history information, such as drug use. In this study, representation of drug use was examined in three types of sources: (1) standards from HL7 and openEHR, (2) clinical text from publicly accessible clinical notes and a local EHR, and (3) research measures from the PhenX Toolkit and CDE Browse. In total, 27 elements were identified across the examined sources, revealing a diverse set of values that were found to be associated with drug use type, frequency, method, time frame, and amount. The findings of this study provide insight into the representation of drug use information that may contribute to efforts for standardizing collection and use of these data to support clinical care and research.

Introduction

Morbidity and mortality from pharmaceutical, over-the-counter, and illicit drug misuse in the United States (U.S.) has increased in recent years, while drug poisoning has become a leading cause of injury deaths1–2. Opioid analgesic poisoning deaths tripled between 2000 and 20103. Opioids and benzodiazepines were the predominant pharmaceutical drugs leading to over 43,000 overdose deaths in 20134. In 2013, 8.8% of adolescents and 9.4% of adults in the U.S. were current (within the past month) users of illicit drugs5. Further, drug misuse has been well documented among youths6 and adults7–8 to be associated with comorbid medical problems and mental health disorders. The consequences of such comorbidities for youths can be substantial – including higher rates of treatment, social and academic problems, and suicide attempts6,7. In the general population, co-occurrence of mental health disorders with drug misuse has been documented for anxiety disorders (with marijuana)9,10 and suicide deaths (with misuse of prescription drugs) in U.S. veterans11. These findings reflect part of the impact of drug use in the U.S. and illuminate the need for standardized representation of drug use in behavioral data that may be used to inform patient care, clinical research, and public health policy.

In recent years, focus on standardized collection of patient information using the electronic health record (EHR) has intensified. The 2009 Health Information Technology for Economic and Clinical Health Act (HITECH) outlined goals for the adoption of EHRs for health providers, in parallel with the objective of “meaningful use” to improve patient care12. The Patient Affordable Care Act of 2010 further emphasized the detection of substance use problems and the integration of care with primary care providers13. The 2013 set of Meaningful Use Objectives from the Centers for Medicare and Medicaid Services contains one core objective for tobacco use (smoking status); however, there were no detailed objectives for other types of drug use14. A collaboration of the National Institute on Drug Abuse Center for Clinical Trials Network (NIDA-CCTN), National Cancer Institute (NCI), and Substance Abuse and Mental Health Services Administration (SAMSHA) supports the development of a standardized clinical quality measure (CQM) that may be considered for inclusion as a Meaningful Use core objective15. In 2014, the Institute of Medicine proposed a new set of standard measures for social and behavioral domains that included evaluation of the ‘Abuse of Other Substances’ domain16,17. However, due to the sensitivity and complexity of data collection for drug misuse, this domain was not included for further consideration for Meaningful Use Stage 3. Existing standards for collection of social history information (e.g., the HL7 implementation guides for Clinical Document Architecture (CDA) Release 218 and the ‘Substance Use Summary’ and ‘Substance Use’ archetypes in openEHR19) that may provide a possible way to represent drug use in EHRs have been assessed in prior work for capturing social history information in clinical notes20.

The EHR has the potential to serve as a powerful tool to support drug use screening, diagnosis, intervention, and treatment for primary care providers21. Wu, et al. examined the prevalence of substance use disorders (SUDs) and

376
patterns of comorbidities in adults by extracting patient information from the ‘Habit/Substance Use’ domain in the EHR at Duke University Medical Center. Prevalence of SUDs differed by sex, race and ethnicity, whereas comorbidities differed by race and sex, and were more prevalent among patients with SUDs than those without. This study provides supporting evidence for the use of EHRs for research to inform health care. Yet, further standardization of patient data is required to support information sharing among providers. Motivated by the 2006 National Institutes of Health (NIH) National Electronics Clinical Trials and Research projects, NIDA-CCTN led an effort to develop sets of consensus-based common data elements (CDEs) for substance use to be used within the EHR and other data sources. The NIH Common Data Element (CDE) Resource Portal promotes the use of CDEs through numerous initiatives, tools, and resources. Among these are the Cancer Data Standards Registry and Repository (caDSR) that incorporates cancer-specific CDEs from numerous sources; Grid-enabled Measures (GEM) that facilitates the development and sharing of common measures; and, Consensus Measures for Phenotypes and Exposures (PhenX) that provides consensus-based standard measures to be incorporated in genome-wide association and epidemiologic research studies. These sources contain CDEs (a single question denoting a fixed representation of a variable) or measures (a standardized instrument containing a protocol with one or more CDEs), which will henceforth be referred to as “research measures.”

With the increased attention to the importance of monitoring and understanding drug use and its impact, there is a need for research focused on comprehensive collection and subsequent use of this information. To address this need, the goal of this study was to examine the representation of drug use in multiple sources for informing EHR and standards development for guiding evidence-based patient care and ultimately improving patient outcomes.

Methods

Study design

Three types of sources were analyzed to identify elements associated with drug use and their corresponding values: (1) standards — HL7 CDA-based models and openEHR archetypes; (2) clinical text — drug use sentences in clinical notes from the publicly accessible MTSamples.com (MTS) resource and drug use comments from the social history module of the Epic EHR at the University of Vermont Medical Center (UVMMC); and (3) research measures — measures including one or more CDEs from the PhenX Toolkit and CDEs from caDSR using the CDE Browser.

Analysis of standards

The first phase involved exploring current standards for collection of social history information related to drug use. The HL7 Implementation Guide for CDA Release 2: IHE Health Story Consolidation, DSTU Release 1.1 was examined for elements within the Social History Observation template of the Social History section. Archetypes for ‘ Substance Use Summary’ and ‘Substance Use’ were also identified using the openEHR Clinical Knowledge Manager. Elements described within these standards were merged with a set of elements identified in previous work involving the analysis of social history information in clinical notes, social and behavioral information in public health surveys, and free-text comments associated with tobacco and alcohol use in the EHR. This combined set of 25 elements was used to create an initial set of annotation guidelines for analyzing the clinical text and research measures.

Analysis of clinical text

The second phase consisted of an analysis of clinical texts from MTS and UVMMC. For MTS, sentences describing drug use were identified within 491 clinical notes categorized as ‘Consult – History and Physical’, which have been used in prior studies, using the General Architecture for Text Engineering (GATE). This provided a set of 130 drug use sentences from 124 (25.3%) notes. At UVMMC, the Epic EHR social history module collects information on drug use using a set of structured fields for Status (‘Not Asked,’ ‘Yes,’ and ‘No’), Use/week, and Type (e.g., benzodiazepines, ‘cocaine,’ ‘marijuana,’ ‘heroin,’ and ‘opiods’) as well as a free-text comment field, which was the focus of this study. A random set of 50 drug use comments from January 2014 was first analyzed to determine if and how to enhance the annotation guidelines. For example, the original element Duration was found to be too broad and led to the creation of more specific elements Duration of Use and Duration Since Time Point. Two annotators (EWC and ESC) annotated a subset of 10% of the 130 MTS sentences and 450 UVMMC comments from March 2014 (representing the most recent comments for a random set of 450 patients), achieving an inter-rater reliability using Cohen’s kappa of 0.92 and 0.94 respectively.
The brat rapid annotation tool (BRAT)\textsuperscript{41,42} was then used to annotate drug use information in the 130 sentences and 450 comments (Figure 1) using the revised annotation guidelines. These guidelines define the elements (e.g., Status, Type, or Time Frame) as well as relationships between elements such as Type and Time Frame (e.g., ‘40 years ago’ => ‘heroin’). Further analysis involved extracting the annotations (representing element-value pairs) and generating statistics for each element and their corresponding values for each source of clinical text as well as the combined set of annotations for MTS and UVMMC. Using the combined annotations, those with similar meaning were grouped by a common word, phrase, or pattern. For example, the grouping ‘Cocaine’ represented the annotations ‘cocaine,’ ‘cocaine drug,’ ‘crack,’ and ‘crack cocaine,’ whereas patterned groupings such as ‘[#] [time unit] ago’ represented ‘days ago’ and ‘over a year ago.’

**Figure 1.** Annotation of clinical text using the brat rapid annotation tool.

**Analysis of research measures**

The third phase of the study involved analysis of the PhenX Toolkit (V5.7; accessed July 31, 2014) containing 21 domains with over 330 measures and the caDSR\textsuperscript{43} using the CDE Browser (V4.0.4; accessed July 31, 2014) providing access to 35 resources containing information about thousands of CDEs. A search for measures using the PhenX Toolkit was done by browsing the domains with a focus on the ‘Alcohol, Tobacco, and Other Substances’ domain, in addition to a search of all measures by using the following search terms: ‘substance,’ ‘illicit,’ ‘illegal,’ and ‘drug.’ The same set of search terms was used to identify measures in the CDE Browser. Cumulatively, an initial set of 111 measures was identified and further restricted by excluding measures that explicitly targeted substance abuse and cessation; emotional, physical or social repercussions of drug use or abuse; or, opinions and perspectives about use or abuse. This resulted in a final set of 40 drug use-specific measures containing 40 questions from CDE Browser and 10 drug use-specific measures containing 191 questions from PhenX Toolkit. For some measures, instructions and supplemental information were also included in the analysis. For example, the measure ‘Patterns of substance use – adults’ in the PhenX Toolkit included a supplemental drug card detailing over 150 drug names and each was designated as a value within the corresponding measure.

**Figure 2.** Analysis of questions and responses within research measures.

Annotation of the measures (Figure 2) was performed using the same guidelines for annotating the clinical text by designating words and phrases within questions as well as the responses to questions as values (each equivalent to one annotation), and then assigning a corresponding element to each value. A new element for Time Point (reference to a particular period of time) was observed within the questions of the PhenX measures and subsequently added to the guidelines. Prior to annotation of the two sets of identified measures, two annotators (EWC and ESC) evaluated
a subset of 10% of the measures from CDE Browser and PhenX Toolkit and achieved an inter-rater reliability using Cohen’s kappa of 0.94 and 0.95 respectively. Similar to the clinical text, further analysis involved extracting the elements and corresponding values and generating statistics for each source as well as the combined set of measures. Using the combined annotations, those with similar meaning were grouped by a common word, phrase, or pattern.

**Results**

The HL7 and openEHR standards, 50 measures from PhenX Toolkit and CDE Browser containing a total of 131 questions, and 130 MTS sentences and 450 UVMMC comments represented a set of 27 drug use elements. Table 1 summarizes the distribution of these elements across the standards, clinical text, and research measures. In addition, this table shows the number and proportion of annotations associated with each element for MTS sentences (465 annotations), UVMMC comments (1,205 annotations), PhenX Toolkit (2,019 annotations), and CDE Browser (343 annotations). Of the 25 elements from prior studies\(^{20, 36, 37}\) (indicated by ‘\*’ in Table 1), 24 retained their original meaning. *Duration* was further demarcated as *Duration of Use* and *Duration Since Time Point*, and a new element *Time Point* was added, which resulted in a total of 27 elements.

**Table 1**: Distribution of drug use elements across sources.

\* number of annotations; \* element derived from previous work\(^{20, 36, 37}\).

As reflected in Table 1, seven elements were represented in the HL7 implementation guide while the openEHR archetypes cumulatively included 15 elements. MTS clinical text and measures from PhenX Toolkit and CDE Browser contained information for 16, 18, and 15, elements, respectively. Clinical text from UVMMC contained the most diverse drug use information representing 23 elements. *Quit Age*, *Change*, and *Triggers* were only found in the openEHR archetypes whereas *Time Frame* (e.g., ‘last 6 months’), *Time Point* (e.g., ‘tonight’), and *Context* (e.g., ‘at
night for sleep’) were specific to the research measures and clinical text. *Situation* (e.g., ‘when going out to eat’) and *Subtype* (e.g., ‘pills: vicodin’) occurred only in clinical text.

Within the standards, values were provided for some elements. For example, in the openEHR archetypes, values for *Status* included ‘current user,’ ‘former regular user,’ ‘former occasional user,’ and ‘never user’ while *Frequency* values included ‘daily use,’ ‘weekly use,’ ‘irregular use,’ and ‘no use.’ In addition, data types were provided that may be used to infer values for some elements (e.g., Date/Time for *Start Date* and *Quit Date*). Analysis and grouping of values focused on six elements that were found to be the most frequent across the clinical text and research measures: *Type, Frequency, Method, Negation, Time Frame,* and *Amount.* Negation was the third most frequently occurring element and included six groups of values: ‘no,’ ‘none,’ and ‘without’ (78 total and 3 unique values in measures) and ‘denies,’ ‘does not,’ and ‘never’ (164 total and 10 unique values in clinical text). Tables 2-6 include the value groupings for the remaining top five elements and shows for each element: (1) total number of values, number of unique values, and number of groups; (2) total number of values per group, frequency of group among the total values for element, and number of unique values within the group; and (3) example values for the highest frequency groups per element.

Table 2 shows the distribution of values for the element *Type* among clinical text and research measures. Values in the group ‘Marijuana’ were among the most commonly observed at a frequency of 6.1% of 842 values (research measures) and 17.6% of 472 values (clinical text) with the values ‘marijuana’ and ‘cannabis’ observed in both sources. The group ‘Marijuana’ also illustrates the occurrence of misspellings and abbreviations among the clinical text as observed with ‘marijana,’ ‘marijuanana,’ and ‘MJ.’ The group ‘Caffeine’ was observed only in clinical text and included values representing coffees, teas, and soft drinks.

Values for the *Frequency* element were categorized into seven groups for the clinical text and research measures with the three most frequent groups represented in Table 3. The group ‘[#] [time unit] per [time unit]’ contained similar values for both sources including ‘daily’ and ‘weekly.’ In contrast, the most common *Frequency* group for clinical text was represented by the group ‘Occasionally’ while the measures reflected more precise values such as exact numbers (e.g., ‘0,’ ‘1,’ and ‘2’) or ranges (e.g., ‘1-2’ and ‘20-39’) in the group ‘[#].’

Table 4 shows that the top four groups for the *Method* element for clinical text and research measures are nearly equal with the exception that the value ‘intake’ appears in the clinical text whereas the value ‘taken’ is found in research measures. Values in the group ‘Use’ were represented in over 50.0% of the total values in clinical text and research measures. Within the measures, the group ‘Inject’ contained more descriptive values in the form of phrases such as ‘injected using needle’ and ‘injection into the skin,’ while clinical text contained more abbreviated values such as ‘inject,’ ‘boot,’ and ‘IVDU.’

For the element *Time Frame* in Table 5, information about a past period of time was represented in research measures by values in the group ‘Past [#] [time unit]’ including phrases such as ‘during the last 30 days’ and ‘past 30 days up to and including today.’ In contrast, a past time period was represented in the group ‘Past’ containing more generalized values such as ‘former,’ ‘past,’ and ‘prior,’ in addition to the group ‘[#] [time unit] ago’ with more precise values including ‘10 years ago’ and ‘1 week ago’ within clinical text.

Discussion

Social and behavioral risk factors such as nicotine or alcohol use are known to impact health and are often documented in clinical settings. However, the collection of drug use information remains complex and often disregarded. Documenting drug use patterns and behavior in the EHR could support research and public health policy; aid physicians and other clinicians in identifying drug misuse, abuse, and dependence; and, highlight risk factors for comorbid conditions that could lead to enhanced patient care through prevention, intervention, and cost-effective, targeted treatment. The findings of this study provide insights into the current scope of the collection of drug use information in clinical and research settings, and reflect the wide variation in the breadth and depth of drug use content within standards, clinical text, and research measures. These findings may be used to inform development of a comprehensive drug use model for guiding improved data collection and use in electronic health sources (e.g., EHRs and surveys), which could be further enhanced by understanding the requirements of different end users and use cases.

Numerous sources of measures related to social and behavioral domains were identified in this study, including caDSR and PhenX Toolkit that were examined. Additional resources were also identified (e.g., GEM) that may be further explored in future work. Of the sources examined, PhenX measures contained the most robust drug use content since some measures contain multiple questions and are supplemented with additional information including lists of drug use methods, amounts, and drug types. By contrast, drug use measures identified in the caDSR using the CDE Browser were represented by a single question with additional information statements for most measures and were from resources including the NCI cancer Biomedical Informatics Grid (caBIG; seven measures), Lombardi Cancer Center (LCC; two measures), National Institute on Drug Abuse (NIDA; 26 measures), National Institute of Dental and Craniofacial Research (NIDCR; one measure), and NCI Programs of Research Excellence (SPOREs; four measures). The challenge of identifying drug use-specific measures across the multitude of resources highlights the need to develop a set of standard measures for this domain and supports the recent focus on adopting standard social and behavioral measures in the EHR.

Collectively, the analysis of standards, clinical text, and research measures revealed a wide-ranging set of drug use values that were represented by 27 elements. The Temporal element was further categorized into a total of nine elements. Start Date and Quit Age were predominantly represented in standards, whereas Start Age and Quit Date were found across the source types. The elements Duration of Use, Duration Since Quit, Duration Since Time Point, Time Frame, and Time Point appeared in clinical text and research measures, and overall, the values for each element were more precisely represented in clinical text. For example, clinical text contained Time Point values such as ‘Saturday,’ ‘15 years ago,’ ‘2006,’ and ‘July 4th’ while ‘first time,’ ‘last time,’ and ‘most recent time’ were found in the measures. These value disparities highlight the inherent difference in purpose between the two sources: clinical text reflects a more factual account of patient history, whereas measures are a clinically investigative tool seeking information using a generalized set of questions. Of note, reference to the age a person used a drug (e.g.,
‘age of 13-14’) appeared only within clinical text and was annotated as a value within Time Frame; however, in future work the element Use Age could be added to represent these values most accurately.

On occasion, the analysis of values presented an organizational challenge. Complex values containing multiple elements were observed in some measures. For example, within the element Amount, the value ‘#’ was further defined by the unit of measure including ‘bags,’ ‘buttons,’ ‘capsules,’ ‘hits,’ and ‘rocks,’ among other units which are nonstandard but have meaning in the drug use community. This finding thereby demonstrates the need for additional delineation of Amount values to include a numerical value as well as a unit of measure. Type values also presented a challenge since they were found in clinical text and research measures in the form of a slang or street name, or common, chemical, or pharmaceutical name. Interestingly, ‘caffeine’ was the second most common Type value in clinical text, motivating the exploration of a separate Caffeine model as a possible next step guided by existing standards such as the ‘Caffeine Consumption’ archetype in openEHR. Groupings for Type were designated either by a single value such as ‘party pills’ or by creating a group for words or phrases clearly representing one concept such as the group ‘Methamphetamine’ which contains the values ‘crank,’ ‘crystal meth,’ ‘meth,’ ‘desoxyn,’ and ‘fumes of crystal meth.’ Next steps for standardization and categorization of Type values may include exploring existing drug terminologies such as RxNorm from the National Library of Medicine44,45 that provides normalized names for clinical drugs, information and categorization of drugs from NIDA46, and the Alcohol and Other Drug (AOD) Thesaurus from the National Institute on Alcohol Abuse and Alcoholism (NIAAA)47. The availability of a comprehensive resource that hierarchically organizes drug types, variant names, and groupings could be valuable for providing flexibility to support different use cases (e.g., selecting a specific drug type versus a more general drug category).

The findings from this study represent a preliminary synopsis of drug use information identified within diverse sources with future goals involving the creation of a formal representation of an integrated drug use model. To that end, a next step could involve retrieving existing codes associated with measures identified in this study. For example, the PhenX measure ‘Substances – 30 day frequency’ correlates to the Logical Observation Identifiers Names and Codes (LOINC) concept with the name ‘PhenX - substance – 30 days frequency protocol,’ whereas the measure ‘Substance Abuse Illicit Substance Cocaine Personal Medical History Frequency’ from the CDE Browser contains the concepts ‘illicit substance,’ ‘cocaine,’ and ‘personal medical history’ with corresponding NCI Thesaurus codes. In addition, drug use values could be mapped to standardized terminologies and coding systems such as SNOMED-CT48 49 and the Unified Medical Language System (UMLS)50. Subsequent model development could also include alignment of these model components with national and international modeling initiatives such as the Clinical Information Modeling Initiative (CIMI)51, with the focus of generating a semantically interoperable drug use model.

Conclusion

Recent focus on promoting the collection of behavioral and social information in the electronic health record has highlighted the needs and challenges in developing standardized measures for these domains, including drug use. This study provides a broad perspective on the current representation of drug use information as reflected by standards, in documentation from clinical settings, and within research measures. The findings further provide a foundation for next steps in the development of a comprehensive drug use model that might be used to support research, clinical, and public health applications.

Abstract

Terminologies can suffer from poor concept coverage due to delays in addition of new concepts. This study tests a similarity-based approach to recommending concepts from a text corpus to a terminology. Our approach involves extraction of candidate concepts from a given text corpus, which are represented using a set of features. The model learns the important features to characterize a concept and recommends new concepts to a terminology. Further, we propose a cost-effective evaluation methodology to estimate the effectiveness of terminology enrichment methods. To test our methodology, we use the clinical trial eligibility criteria free-text as an example text corpus to recommend concepts for SNOMED CT. We computed precision at various rank intervals to measure the performance of the methods. Results indicate that our automated algorithm is an effective method for concept recommendation.

Introduction

Over years, researchers have stressed on the importance and usefulness of developing domain-specific terminologies in biomedical informatics. Well-curated terminologies provide cohesive and structured domain knowledge to clinical information systems, such as clinical decision support systems and Electronic Health Record systems, further facilitating the interoperability among them. Natural Language Processing (NLP) applications in biomedical informatics also largely rely on controlled terminologies and ontologies. Concept coverage is an important aspect of Cimino’s desiderata for terminologies (1). Good coverage requires timely and continuous concepts updating with terminologies to keep up with the non-stop growth of domain knowledge and the evolution of professional vocabularies. However, developing and maintaining a high-coverage terminology is a complex and expensive task that often requires constant laborious curation. Such manual effort involves domain experts who are required to read as much domain-specific literature as possible in order to identify meaningful concepts to insert into a terminology.

Due to limited resources and the subjectivity of domain experts in the manual curation process, terminologies vary in their coverage of domain concepts. As such, they are often criticized for insufficient coverage of concepts and concept relations such as synonyms (2). Recently, informatics tools are being used in order to ease the load on curators. BioPortal developed by, Nation Center for Biomedical Ontology (NCBO) (3) and Collaborative Protégé by Stanford (4) are some of the recent developments that facilitate continuous development of terminologies from geographically distributed locations. These tools facilitate continuous interaction between users and developers with the intent to improve terminology development through constructive feedback.

To complement the top-down approach for terminology development driven by domain experts, symbolic and statistical ontology learning methods have been proposed for identifying important concepts from human-generated texts. Hearst introduced a symbolic method to discover hyponyms within Lexical-Syntactic Pattern (LSPs) extracted from text (5). Liu et al. (6) further applied Hearst’s LSP method to identify clinically meaningful concepts and relationships from medical documents. They used regular expressions over Part-of-Speech (POS) tags to extract LSPs in medical documents and asked human annotators to identify meaningful concepts in these patterns. Church and Hanks proposed a statistical method for estimating word association norms to identify useful concepts (7). A symbolic-and-statistical hybrid approach was proposed to identify meaningful concepts by computing the similarity between unrecognized concepts and existing concepts in controlled terminologies (8). Recently, He et al. (9) proposed a structural method leveraging UMLS’s native term mapping and hierarchical structure to identify potentially missing concepts for a source terminology.

Even though the aforementioned approaches have achieved promising results, they all require human experts to suggest and review the concepts. In this work, we present a purely computational method for recommending new concepts with a minimum of human intervention. Unlike above mentions approaches, our method does not rely on domain heuristics or manually crafted rules; it characterizes the concepts using a set of features, which in turn is used to recommend new concepts to a source terminology. The contribution of this paper is two-fold:

(1) We propose a novel, unsupervised approach for prediction and recommendation of phrases as candidate atoms in an existing terminology based on concept similarities; and
(2) We present a cost-effective evaluation methodology to estimate the performance of the terminology enrichment method. Through experimental evaluation on large datasets, we show the accuracy of our recommendation approach, and demonstrate its potential to improve the scalability and throughput of terminology enrichment.

Methods

Glossary and Design Rationale

Before describing our methodology, we clarify the definition of concept, atom, and n-gram, which are key to understanding our approach.

- **Concept** is the fundamental unit of meaning in ontology. According to the semiotic triangle theory (10), each object in the world has one and only one concept describing it, but the concept may be associated with multiple terms, which are also called atoms. Concepts are assigned a unique identifier, such as the unique reference as an identifier (e.g., Concept Unique Identifier in the Unified Medical Language System (UMLS) that can be used to unambiguously identify a concept. Each concept is associated with at least one or more lexical variants or natural language text strings, which is often referred to as atoms in the UMLS.

- **Atom** is the smallest unit of meaning contributed by a source. Atoms are phrases (i.e. sequence of terms) that represent a distinguished meaning. A unique identifier is often assigned to an atom, such as the atomic unique identifier (AUI) in the UMLS. Atoms are symbols representing a concept, which contain one or more atoms.

- **N-Gram** is a contiguous sequence of n terms found in text. For example, *lymph node metastasis* is a 3-gram (or tri-gram). An n-gram deemed meaningful by a terminology curator becomes an atom.

The goal of our study is to identify in a collection of written texts of a particular domain, the n-grams that are highly probable of constituting an atom in an existing terminology; and to recommend them as candidate atoms to the curators. It is the decision of the curators to enrich the terminology accordingly by approving the candidates as atoms to an existing concept or a new concept in the terminology.

Our proposed method requires two components as input: seed terminology and a text corpus. We explain each of these components, our proposed approach to recommend new concepts and the evaluation strategy below.

Dataset

*Seed Terminology* is the terminology to be enriched using the text corpus. It must have at least two components: a set of concepts and a set of lexical variants or terms for each concept. Following de Keizer’s definition (11), a concept is a “cognitive construct of objects” that consists of one or more terms, which are also referred as atoms. For example, a concept “breast cancer” might have the following atoms: “Malignant neoplasm of breast”, “breast cancer”, etc. In the UMLS, atoms are often assigned an atomic unique identifier (AUI).

*Text Corpus:* A large set of unstructured text on a specific domain from which concepts are to be extracted. Text documents and literature are valuable sources for identifying new concepts on a domain. The written text must ideally be a representative sample of the knowledge prevalent in the domain. It is important that the text exists as free-text as our approach relies on occurrence frequency as well as linguistic properties of a concept in the text. The goal in this work is to identify potential atoms from the text to enrich an existing terminology.

![System outline illustrating various modules in our proposed approach.](image)

**Figure 1 – System outline illustrating various modules in our proposed approach.**
Approach

Our proposed approach takes two data sources as input: seed terminology and text corpora, and outputs a ranked list of n-grams that are most likely to be added to the seed terminology as atoms. The fundamental premise of our approach is that the characteristics of n-grams that are already atoms in the seed terminology can be automatically learned and used to recommend new atoms that can be added to the seed terminology.

Figure 1 provides an outline of our approach. For a given text corpus, the text is preprocessed by identifying set of sentences. Then, a set of n-grams is extracted from each sentence. The extracted n-grams are aggregated and each unique n-gram is characterized using a set of features. We use a set of morphological, contextual, and syntactic features to capture the characteristics of an n-gram that represents a concept. Of all n-grams identified in the text corpus, a subset of them can be matched to atoms in a seed terminology. We leverage this information to learn a model that characterizes an atom using a set of features. Considering each atom identified in the text corpus as a candidate atom, the model is used to score these candidate atoms indicating the likelihood of them being suitable to be an atom in the seed terminology. A summary of various steps involved are listed below:

1. Preprocessing the text corpus;
2. Identifying n-grams from text and extraction of features for each n-gram;
3. Learning the characteristics of those n-grams that belong to the seed terminology;
4. Leveraging the learnt characteristics to recommend new atoms to the terminology;

Step 1: Pre-processing: The first step is to segment the free-text from the text corpus into sentences. We relied on OpenNLP (12) to perform sentence segmentation. Each sentence was tokenized and n-grams were extracted by iterating over the tokens (up to 5-grams are extracted). The extracted n-grams were filtered if the n-gram begins with a number token or a stop-word, or if the n-gram ends with a stop word. We used a Standard English stop-word list in our experiments.

Step 2: Feature Extraction: The problem of identifying meaningful atoms in free text is similar to the named entity recognition (NER) problem (13). Inspired by the research in NER, we engineered a set contextual and syntactic features to represent the n-grams extracted from the text corpus (13, 14). The feature representation of n-gram is not specific to any terminology or text corpora. This is an important property of our method that enables our method to be used across other domains. The engineered features include:

- Capitalization Features (CAP): the capitalization information of the first and all letters, and the first letters of each tokens of the current n-gram;
- Syntactic Features (POS): the part-of-speech (POS) tags of the current n-gram;
- Contextual Features (CONTEXT): the POS-tags, tokens and the prefixes/suffixes of the tokens that co-occur with the current n-gram within a window of 10 tokens;

![Figure 2 – Feature extraction example for the unigram “chemotherapy”. (a) Capitalization Features, (b) Syntactic Features, and (c, d, and e) Contextual Features.](image-url)
We illustrate the feature extraction process with an example in Figure 2, the example shows two different sentences containing “chemotherapy”, which is the unigram under consideration. The feature extraction process starts with the tokenized and POS-tagged sentences. In Figure 2, (a) represents the capitalization features; (b) illustrates the syntactic features of the unigram; and (c, d and e) are the contextual features that include frequencies of POS-tags, tokens, and prefixes/suffixes of the surrounding tokens within a windows size of 10. As suggested in the literature, the length of the prefixes and suffixes was limited to 3 characters. The feature vector of the unigram was obtained by concatenating of the features shown in (a, b, c, d and e).

Step 3: Learning Module: Once the n-grams were characterized by a set of features, the next step was to build a model that accurately represents n-grams that were the concepts belonging to the seed terminology using our feature representation. Thus, we split the n-grams identified into two sets: n-grams that were concepts in the seed terminology (Concept Set) and n-grams that were not in the seed terminology (Candidate Atom Set). Note that the concept set here was automatically generated using the seed terminology and the text corpus.

The n-grams in the candidate atom set are represented using a set of features, and clustered using the K-means algorithm as shown in Figure 3. The rationale behind clustering is that the groupings would represent different characteristics of an n-gram that are atoms in the seed terminology. We hypothesize that the clustering categorizes the characteristics of the atoms in a seed terminology, thereby improving recommendation of candidate atoms. Determining the right number of clusters is not obvious for a given dataset, several methods exist for the finding the optimal k in K-means (15, 16). We prune those clusters that contain less than 1% of the total n-gram. The pruning was performed to eliminate less representative clusters that could introduce noise into our model.

Centroid linkage function: the minimum Euclidean distance between the feature vector of an n-gram and the cluster centroids.

\[
\text{score}_i = \min\left( \text{dist}(x_i, c_j) \right), \quad j \in \{1, 2, \ldots, C\}
\]

Where, \( i \) is the \( i^{th} \) n-gram in the set; \( x_i \) is the feature vector of the \( i^{th} \) n-gram; \( C \) is the cluster count; \( c_j \) feature vector of the centroid in \( j^{th} \) cluster, and \( \text{dist}(x_i, c_j) \) is the function that measures the Euclidean distance between two vectors.

Number of Clusters: The value of \( k \) in k-means is determined using a cross-validated likelihood criterion (16). The method follows a cross-validated clustering approach to provide insights about cluster structure. The concept set (CS) was split into 10 folds. For each fold, samples from the training folds were clustered using k-means with different \( k \) values.

The sum of average differences between the samples in the test set and the nearest cluster centroid were computed. The computed sum is called the average minimum distance. Figure 4 shows the average minimum distance for
various $k$ values. It can be seen that the minimum average distance stabilizes for $k$ values between 30 and 40, which can be used for an indication of the optimum number of the clusters.

![Graph showing the average minimum distance scores for various $k$-values.](image)

**Figure 4 - The average minimum distance scores for various $k$-values.**

**Evaluation**

In this section, we describe the evaluation measures and the details of the dataset used in our study to evaluate our proposed approaches.

**Evaluation Measure:** We use precision at various rank levels ($r$) to evaluate our atom recommendation algorithm. Precision at rank $r$ is commonly used for various ranking problems to measure the effectiveness. Precision at rank $r$ is the fraction of retrieved n-grams that are indeed meaningful atoms.

$$\text{Precision}@r = \frac{\# \text{of n-grams identified as meaningful atoms}}{n}$$

Where, $k$ is the rank cut-off. We compute precision at $r = 1000, 5000$ and $10,000$, as it is reasonable to assume that a terminology curator enriching a terminology such as SNOMED CT (containing about 300,000 active concepts) would be willing to manually go through at least 5000 n-grams. Since, the task at hand is to re-rank the atoms in the candidate atom set (CAS), traditional ranking measures such as recall and F-measure are not informative.

**Domain-Specific Text Corpus:** We use the ClinicalTrials.gov dataset that is a rich source of information containing a set of eligibility criteria used by clinical researchers (17). The dataset was created by the National Library of Medicine and is publicly available. Each clinical trial consists of various structured fields such as study title, sponsor, etc., and a free text eligibility criteria field that contains the criteria for inclusion and exclusion of a participant. The eligibility criteria define various patient characteristics that make a person eligible or ineligible for a research study. We make use of the eligibility criteria free text field for the purpose of this study. We downloaded 181,356 (as of February 2015) clinical trial summaries for our experiments.

**Seed Terminology:** For the purpose of this experiment, we assume that SNOMED CT is the only available terminology at hand so that we do not consider the possibility of one term belonging to multiple terminologies simultaneously. SNOMED CT is one of most comprehensive clinical publicly available clinical terminology and is maintained and distributed by International Health Terminology Standards Development Organization (IHTSDO). We obtained the latest version of SNOMED CT available as part of the UMLS Metathesaurus (version 2014AA) from the NLM website. Our algorithm intends to extend SNOMED CT terminology with atoms relevant to the clinical domain using free-text clinical trial eligibility criteria.

**Labeled Data:** In order to evaluate our proposed methodology, we require a set of n-grams with positive and negative labels, i.e., positive n-grams are meaningful atoms whereas negative refers to a meaningfulness n-gram. As human annotations are extremely expensive and time consuming, we built our labeled data using various terminologies that are part of the UMLS, which were curated by experts from different domains. All n-grams identified in the ClinicalTrials.gov dataset that were part of a terminology (other than SNOMED) were labeled positive and the rest were labeled negative. It is certainly possible that a negatively labeled n-gram could still be meaningful, UMLS terminologies are not complete and there may still be meaningful n-grams not part of the UMLS. Nevertheless, the simulated labeled data provides a cost-effective, quick, and reasonable lower-bound performance estimate of our proposed methods.
Results

Dataset Statistics

We used the free-text clinical trial eligibility criteria to extract all possible n-grams. The n-grams were preprocessed to remove stop-words and numbers as described in the pre-processing step. We extracted up to 5-grams that occurred at least 5 times in the corpus to filter out misspelled or noisy n-grams. The pre-processed n-grams were categorized into concept set (CS) and candidate atom set (CAS). An n-gram that matched against an atom in SNOMED belonged to the CS and all other n-grams belonged to CAS.

Table 1 shows the total number of unique n-grams extracted. Only 5% of those n-grams matched against an atom in the SNOMED. Of the remaining 429,465 n-grams, about 6% (25,291 n-grams) matched against an atom in the UMLS (other than SNOMED). The 25,291 n-grams constitute our positive labels and are used only for evaluation purpose. The remaining 404,174 n-grams belong to the candidate atoms set (CAS); the n-grams in CAS are to be ranked by our recommendation algorithm.

Lower Bound Precision Scores

The candidate atoms in CAS were ranked by our algorithm, which promoted n-grams that are relevant to the seed terminology higher and suppressed meaningless n-grams. An n-gram in CAS that matched against an atom in UMLS (other than SNOMED CT) was considered as true positive. Those n-grams that do not match are considered as true negatives. We computed precision at various rank intervals (1000, 5000, 10000 and 20000), to estimate the effectiveness of our approach.

As described in the methods section, the choice of features used to represent n-grams influences the performance of the recommendation algorithm. Therefore, we experiment with different sets of features. We experimented with different feature sets and their combination of the capitalization (CAP), syntactic (POS) and contextual features (CONTEXT). In order to observe the effect of the syntactic information, we merged all the syntactic information under the feature set named POS (including the syntactic information involved in the contextual feature set).

In addition, we included two baseline methods for the comparison: a random ranking and frequency-based. The random ranking baseline was obtained by randomly sampling 20,000 n-grams from the candidate atom set (CAS). The frequency-based ranking was obtained by sorting n-grams in the candidate atom set (CAS) by frequency of their occurrence in the text corpora.

Table 2 provides the accuracy scores for various methods at various rank intervals r. The results show that our algorithm performs considerably better than a frequency-based baseline. Note that, especially for larger r values the difference between our recommendation algorithm and the frequency baseline is more apparent. It is observed that the inclusion of the POS features further increases the precision by 5%. The best results were obtained using all the features (CAPS+POS+CONTEXT) that represent an atom.

Top-10 n-grams
Table 3 shows the top ranked atoms categorized by 1, 2, 3, 4, and 5 grams. The atoms that belong to a terminology in the UMLS are italicized and the rest are highlighted in grey. It is interesting to note that atoms such as “history of sleep apnea”, “hormonal treatment” are meaningful but are not part of any existing UMLS terminology.

Examining the top ranked n-grams lead to a few interesting observations. We found that there existed meaningful n-grams that did not match against the UMLS in the top ranked list. Thus, we decided to investigate this further by estimating the number of meaningful n-grams (candidate atoms) that are not part of the UMLS. We used the help of a physician to determine if the candidate atoms are meaningful concepts. The physician was provided a list of 100 n-grams that were not matched against a UMLS terminology for manual review.

The top 100 n-grams were obtained using the algorithm with the best precision score (as shown in in Table 2); and 37 of the n-grams in this were labeled as meaningful. The annotations clearly indicate that there exist several n-grams that are currently not part of the UMLS. The annotation effort was preliminary step and we plan to perform a comprehensive evaluation in the future.

Table 3 – Top 10 n-grams (n ∈ [1-5]) ranked by our recommendation algorithm. N-grams that matched to UMLS concepts are italicized, and n-grams that did not match are highlighted in gray.

New Concepts vs. Synonyms
The precision at rank interval is computed by dividing the number of n-gram identified as an atom of the concept by rank interval. The number of n-grams can be categorized into two groups: n-grams that would be added to the terminology as a new concept from the atoms that will be added as synonyms to an existing concept. This enables us to separate atoms of new concepts from atoms of existing concepts in the terminology. The analysis on our results revealed that on average at least 45% of the n-grams were atoms of existing concepts (often referred to as synonyms in the literature) and the remaining were atoms that belong to new concepts to be added to the seed terminology.

Discussion

Cluster Analysis
In the learning module, the n-grams in the concept set (i.e. n-grams that are atoms in SNOMED CT) are clustered based on their distance between the feature vectors. We hypothesized that the clustering would group similar atoms into the same cluster. We analyzed each cluster by manually reviewing 100 n-grams closest to the cluster centroids. The intention was to identify similarities between n-grams in the cluster or manual label.

Table 4 illustrates a set of 10 n-grams for four clusters that are closest to their centroids. Interestingly, Cluster 1 tends to consist of atoms relating to geographic locations or place names. Cluster 3 contains abbreviations. The atoms in Cluster 2 contain atoms following a specific pattern, this is somewhat expected due to the fact that the atoms are represented using syntactic features. Cluster 4 groups adjectives that are prevalent in the clinical domain.

Further, we tried to align the clusters with the semantic hierarchies present in SNOMED CT. The concepts in SNOMED CT are organized into 19 acyclic taxonomic (is-a) hierarchies. We observed the distribution of the semantic hierarchies in each cluster. For example, 48% of the concepts found within a cluster belonged to the hierarchy “Staging & Scales”, 72% of the concepts in another cluster belonged to “Situation with Explicit Context”. However, only a weak correlation was observed between the clusters and SNOMED CT hierarchies.

**Modifier Extraction**

Modifiers are terms or phrases that provide additional meaning to a concept. For instance, in the phrase *history of heart disease*, the prefix *history of* modifies the meaning of the concept *heart disease*. Modifiers play an important role in tasks such as cohort identification. A researcher looking for cohort of patients with “history of heart disease” might possibly find little use with patients with “active heart disease”. As an extension to this work, our intention is to identify candidate modifier that enrich the identified concepts.

Table 5 – Candidate modifiers identified from the top ranked n-grams.

<table>
<thead>
<tr>
<th>history of</th>
<th>severe</th>
<th>significant</th>
<th>active</th>
<th>previous</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>evidence of</td>
<td>diagnosis of</td>
<td>treatment with</td>
<td>prior</td>
</tr>
</tbody>
</table>

We manually analyzed the top ranked n-gram and found that the 3-, 4- and 5-grams tend to contain a modifier followed by a concept. Following the manual analysis, we wanted to identify those n-grams that matched the pattern; prefix followed by UMLS atom. Using regular expressions we filtered all n-grams that matched the <prefix, atom> pattern. We found 14,000 n-grams that contain a prefix followed by a UMLS atom, i.e., partially matched against an atom in UMLS. Further, we ranked the prefix by its frequency; hypothesizing that commonly used modifiers would be ranked higher.

Table 5 shows the top 10 candidate modifiers extracted using this approach. The results are promising and we plan to investigate further in this direction.
**Post & Pre Coordination**

SNOMED Clinical Terms (SNOMED CT), as the most comprehensive multilingual clinical terminology, is being widely implemented as a standard within HITSDO member countries. By 2015, SNOMED CT will be the United States standard for encoding diagnoses, procedures, and vital signs in electronic health records (EHRs) under Stage 2 of Meaningful Use (18). Even though SNOMED CT provides rich conceptual content, researchers have advocated greater coverage of common problem statements with improved synonymy and conceptual content (19). A survey among the direct users of SNOMED CT reported that 23% and 17% of the respondents encountered missing concepts and missing synonyms, respectively (2).

Post-coordination of SNOMED CT allows its users to create new meaning by combining existing concepts, which can potentially enhance SNOMED CT’s conceptual coverage (20). In spite of post-coordination, researchers reported that some clinical statements with complex and rare clinical scenarios could not be encoded (21). Meanwhile, the same clinical meaning may be represented by different post-coordinated expressions, which hampers their interoperability among different authoring entities. In the setting of this paper, post-coordinated expressions may also pose difficulties in unifying and structuring clinical trial eligibility criteria.

To the best of our knowledge, there is no tool available for automating the creation of post-coordinated expressions. Therefore, they have to be modeled by a clinical expert manually. In this proof-of-concept study, we consider only pre-coordinated SNOMED CT concepts for training and prediction. Computational approaches to filter out suggested concepts that can be constructed with post-coordination need to be developed. Nevertheless, the suggested concepts were identified to be important in clinical trial eligibility criteria, thereby should be considered by SNOMED CT curators as pre-coordinated concepts.

**Limitations**

Since the recommendation algorithm relies on linguistic features of atoms extracted from the text corpus, the corpus must contain atoms already present in the seed terminology. Also, our method recommends atoms of a concept and does not provide any information about the relationship between the atoms and concepts. For instance, the algorithm would identify “sleep disordered breathing” and “breathing disorder during sleeping” as meaningful atoms although it provides no information w.r.t its relation with the concept Sleep Apnea. The problem of finding if an atom belongs to an existing or new concept is still an open research area that warrants more investigation. Another limitation is that, we rely on exact string matching between n-grams and atoms in a terminology, which could be error-prone. Although fuzzy matching of text is possible, we argue that an exact string matching provides a more accurate estimation.

**Future work**

In the future, we intend to conduct a larger-scale comprehensive evaluation study using domain experts to accurately estimate the performance of our methods. The manual evaluation process would require the experts to review each candidate atom to determine if the recommended atoms are meaningful or not. Also, we plan to compare our approach with previously proposed symbolic and statistical ontology learning methods (3, 6, 7). Another avenue of future work is to recommend sentences that are highly probable contain new atoms/concepts. Ranking sentences has an advantage, it provides context to the atoms that enables curators to make better decision about atom’s usefulness to a terminology. We also plan to experiment with different datasets from heterogeneous domains to prove the generalizability of our proposed approach.

**Conclusions**

This paper contributes a similarity-based approach for recommending candidate n-grams to terminology curators for consideration. The method characterizes the n-grams in a text corpus by using a feature set to learn important features of a concept in order to produce a ranked list of n-grams by decreasing order of meaningfulness. The ranked list of n-grams would enable quicker and easier identification of new concepts for an existing terminology. Another contribution of this paper is a cost-effective evaluation methodology to estimate the performance of the terminology enrichment method. Through careful experimental design, we simulate labeled data using various terminologies in UMLS to evaluate effectiveness of our proposed approach. We computed the precision score and observed that our method provides about 20% improvement over a frequency-based baseline. We have only scratched the surface of what is possible. There is ample opportunity for work within this framework such as scoring methods for ranking candidate atom, and post filtering of candidate atoms.

Abstract

Asthma is the most common chronic childhood disease and has seen increasing prevalence worldwide. While there
is existing evidence of familial and other risk factors for pediatric asthma, there is a need for further studies to
explore and understand interactions among these risk factors. The goal of this study was to develop an approach for
mining, visualizing, and evaluating association rules representing pairwise interactions among potential familial
risk factors based on information documented as part of a patient’s family history in the electronic health record. As
a case study, 10,260 structured family history entries for a cohort of 1,531 pediatric asthma patients were extracted
and analyzed to generate family history associations at different levels of granularity. The preliminary results
highlight the potential of this approach for validating known knowledge and suggesting opportunities for further
investigation that may contribute to improving prediction of asthma risk in children.

Introduction

Asthma is the leading chronic condition in children globally and has seen a dramatic increase in prevalence over the
last few decades\textsuperscript{1-3}. Several reports have described the need to better understand the effect of genetic, environmental,
and lifestyle factors and their interactions for improving pediatric asthma management\textsuperscript{4-7}. With respect to familial
risk factors, a number of studies have focused on exploring family history of asthma or atopic disease as a potential
predictor of asthma risk in children\textsuperscript{8-11}. These studies have primarily involved use of questionnaires and examined
the effect of asthma in first- and second-degree relatives (parents, siblings, and grandparents) and in multiple
relatives. One study described the low positive predictive value of a family history of asthma; however, it did
conclude that this could be a useful predictor for some preventive health efforts and further studies are needed to
understand the role of family history in risk assessment for pediatric asthma\textsuperscript{10}.

The electronic health record (EHR) offers a potentially valuable source for supporting such studies since information
pertaining to potential familial risk factors is increasingly collected as part of a patient’s family history in addition to
patient-specific diseases and conditions longitudinally over time\textsuperscript{12,13}. This information may be documented in
multiple places throughout the EHR in structured or free-text form, thus requiring the development of approaches to
extract, standardize, and integrate the information for subsequent analysis. To date, there have been some efforts
focused on improving documentation and use of family history in the EHR including a Stage 2 Meaningful Use
measure specifying structured data entry for one or more first-degree relatives in more than 20% of patients\textsuperscript{14},
specifications and models for representing family history\textsuperscript{15,16}, and development of natural language processing
(NLP) techniques for extracting family history from clinical notes\textsuperscript{17-20}.

Knowledge discovery and data mining approaches have the potential to transform EHR data into actionable disease
knowledge\textsuperscript{21-24}. Such approaches have been used to study a variety of disease relationships (e.g., disease-disease and
disease-drug) using both structured data (e.g., from problem and medication lists) and free-text within clinical notes
from the EHR\textsuperscript{25-29}. Association rule mining is a commonly used data mining technique for discovering “interesting”
relationships between items (e.g., family history) in large datasets (e.g., from the EHR) that could contribute to
generating hypotheses for further investigation\textsuperscript{30}. An association rule is represented as $X \Rightarrow Y$ (e.g., if patient has a
family history of $X$, patient also has a family history of $Y$) where $X$ is referred to as the antecedent or left-hand-side
(LHS) of the rule and $Y$ is referred to as the consequent or right-hand-side (RHS) of the rule. A number of
“interestingness” measures (e.g., support, confidence, lift, chi-square, and odds ratio) can be calculated to convey
the strength of a given rule\textsuperscript{31}. Typically, minimum thresholds are specified for support (e.g., proportion of patients
with a family history of $X$ and $Y$ relative to all patients) and confidence (e.g., proportion of patients with a family history of $X$ and $Y$ relative to patients with a family history of $X$) as a mechanism for constraining results.\textsuperscript{30}

The collection of family history data in EHR systems provides an opportunity for validating known associations and for potentially discovering new knowledge of interactions among familial risk factors and diseases. The objective of this study was to develop an approach for mining and visualizing family history associations in the EHR using open-source technologies. As a case study, the approach was evaluated for a particular condition, pediatric asthma.

**Methods**

Figure 1 provides an overview of the approach used in this study that is based on the processes for Knowledge Discovery in Databases\textsuperscript{32} and Disease Knowledge Discovery\textsuperscript{23}. The four major steps involved: (1) data selection to identify a cohort of pediatric asthma patients and extract associated family history entries from the EHR, (2) preprocessing and transformation to prepare the dataset for mining and visualization at different levels of granularity, (3) data mining to generate basic statistics and association rules, and (4) interpretation and evaluation to visualize and validate the family history associations. A combination of Ruby (2.0.0) and R (3.1.2), integrated using the RinRuby Ruby gem (2.0.3), were used for the various processing and analysis tasks.

**Data Selection**

At the University of Vermont Children’s Hospital, the Epic EHR (Epic Systems Corporation, Verona, WI) has been in use since 2009 and includes a module consisting of both structured and free-text fields for collecting family history information.\textsuperscript{33} Two of the structured fields were the focus of this study: (1) problem – selected from a list of 222 values such as “Asthma,” “Cancer,” or “*” for Other that can be further specified in a free-text comment field (not included in this study) and (2) relation – selected from a list of 22 values including “Father,” “Maternal Grandmother,” “Other” that can be further specified in the free-text comment field (not included in this study), or “Neg Hx” for indicating a negative family history of the selected problem (Table 1).

A dataset of structured family history entries was created for a cohort of pediatric asthma patients identified using the following criteria: (1) at least one encounter in 2014, (2) age 3 to <18 years old, and (3) ICD-9-CM code 493* as an encounter diagnosis in 2014 or on the problem list. The most recent set of family history entries (consisting of the problem and relation fields) associated with an encounter in 2014 were then obtained for each patient in the cohort.

*light grey shading indicates excluded field or entry for this study; “*” indicates not applicable or cannot be inferred from structured relation field.
Preprocessing and Transformation

The full dataset was divided into two subsets for: (1) positive family history – entries associated with positive family history of a problem (i.e., any relation except for “Neg Hx”) and (2) negative family history – entries associated with negative family history of a problem (i.e., relation specified as “Neg Hx”). Within these subsets, entries with “*” selected as the problem were excluded since they do not specify a particular problem in structured form (but may include information in the free-text comment field).

For the positive family history subset, four datasets were created to enable subsequent analysis at different levels of granularity:

1. Family history of problem P – only includes the problem from entries for each patient (pos_problem dataset)
2. Family history of problem P in relation R – includes problem and relation from entries for each patient (pos_problem_relation dataset)
3. Family history of problem P in side of family S – includes problem and side of family (i.e., maternal or paternal) determined based on specified relation (pos_problem_side dataset) (Table 1, Column 4)
4. Family history of problem P in degree of relationship D – includes problem and degree of relationship (i.e., first or second) determined based on specified relation (pos_problem_degree dataset) (Table 1, Column 5)

For the negative family history subset, one dataset was created for negative family history of problem P that only included the problem from entries for each patient (neg_problem dataset).

The five resulting datasets were transformed into a common format in preparation for the subsequent data mining step. In this format, each row includes the patient identifier (e.g., random number) and information associated with a single entry separated by the “|” character. For example, “2|Asthma|” in the pos_problem dataset, “2|Asthma_Mother|” in the pos_problem_relation dataset, “2|Asthma_maternal|” in the pos_problem_side dataset, and “2|Asthma_first|” in the pos_problem_degree dataset.

Data Mining

For each dataset, basic statistics were calculated for ranking problems based on frequency and prevalence (pos_problem, pos_problem_relation, and neg_problem datasets only for the latter). Prevalence of a family history problem was determined relative to all family history entries associated with encounters in a particular year (2014 for this study) using a formula similar to term frequency-inverse document frequency (TF-IDF) that is often used in information retrieval to reflect importance of a term relative to a document in a collection:

\[
PREV(p_d) = \frac{\sum p_d}{N_d} \times \log \left( \frac{N_y}{\sum p_y} \right)
\]

where \( p_d \) represents patients with a family history of problem \( p \) in a cohort for a particular disease \( d \) (pediatric asthma), \( N_d \) is the total number of patients in the disease cohort, \( N_y \) is the number of patients with family history entries in year \( y \) (e.g., 2014), and \( p_y \) is the number of patients with a family history of problem \( p \) in that year.

Association rule mining was performed using the arules R package (1.1-6) that interfaces with a C implementation of the Apriori algorithm. With arules, minimum thresholds for support and confidence as well as maximum length of rules can be specified. Numerous other interestingness measures such as lift, chi-square (\( \chi^2 \)), and odds ratio can also be calculated for further filtering and ranking of the generated rules. Analysis of each dataset was performed using different combinations of minimum support values (0.0 to 0.1 in 0.01 increments) and minimum confidence values (0.0 to 1.0 in 0.1 increments). The maximum rule length was restricted to two in order to focus on pairwise associations. In addition to support and confidence, \( \chi^2 \) was also calculated and used to rank rules as this measure was found to outperform other measures in prior studies.

Interpretation and Evaluation

To facilitate interpretation, the arulesViz R package (1.0-0) was used that implements ten visualization techniques for exploring association rules generated by arules. Three types of visualizations were selected for viewing all rules or subsets of rules (i.e., top 50) in each dataset: (1) scatter plot that highlights the distribution of rules relative to specified measures (e.g., support, confidence, and \( \chi^2 \)), (2) graph-based that displays vertices representing items or itemsets and edges representing relationships in rules, and (3) grouped matrix-based that uses a balloon plot for
displaying rule antecedent groups as columns and rule consequents as rows. For the latter two visualizations, support and \( \chi^2 \) were specified as the measures for depicting rule strength based on color and size of nodes respectively. For larger sets of rules (i.e., all), arulesViz was used to export rules to a GraphML format for interactive visualization using tools such as Gephi\textsuperscript{37}.

As an initial validation of the results, several literature sources were reviewed for known familial risk factors and comorbidities, including chapters on asthma within pediatric textbooks\textsuperscript{39-40} and published studies or reports focused on pediatric asthma\textsuperscript{8-16,41}. Two pediatric clinical experts (RCW and PTR) also provided further interpretation of the family history associations.

### Results

Using the specified criteria, 2,048 pediatric asthma patients were identified where 882 (43.1%) were from problem list only, 68 (3.3%) from encounter diagnosis only, and 1,098 (53.6%) from both. Of these patients, 1,646 (80.4%) had at least one family history entry since 2009 and 1,531 (74.8%) had entries associated with encounters in 2014; this latter set formed the cohort for this study. Of the 10,260 most recent family history entries for this cohort (as of December 31, 2014), 7,722 (75.3%) were associated with positive family history and 2,538 (24.7%) with negative family history. After excluding entries with *“* indicated as the problem, 7,342 (71.6%) positive and 2,535 (24.7%) negative family history entries remained. Table 2 includes the distribution of entries, age associated with the most recent set of entries, and sex for the full dataset as well as the positive and negative family history subsets.

The frequency and prevalence of family history problems for the pediatric asthma cohort were determined for the `pos_problem`, `pos_problem_relation`, and `neg_problem` datasets. Table 3 includes the top 10 family history problems, family history problems with relations, and negative family history problems ranked by prevalence.

For each of the five datasets, pairwise association rules were generated using different thresholds for support and confidence. Figure 2 depicts the change in number of rules depending on the thresholds used for the `pos_problem` dataset. Rules generated using “low” thresholds (minimum support of 0.01 and confidence of 0.1) and “intermediate” thresholds (minimum support of 0.03 and confidence of 0.3) were selected for further review.

Figure 3 includes scatter plots of the 194 and 242 rules generated using the low thresholds for the `pos_problem` and `neg_problem` datasets respectively. The upper left quadrant highlights rules that do not occur frequently (based on support value), but have a higher \( \chi^2 \) value. The top rules based on \( \chi^2 \) for the `neg_problem` dataset involved negative family history of “Severe Sprains,” “Broken Bones,” “Collagen Disease,” “Dislocations,” and “Scoliosis” (e.g., \{Severe Sprains\} \( \Rightarrow \) \{Broken Bones\} and \{Collagen Disease\} \( \Rightarrow \) \{Dislocations\} with support=0.08 and \( \chi^2=352 \).

Figure 3: Scatter plots showing the distribution of rules for pos_problem (a) and neg_problem (b) using minimum support of 0.01 and confidence of 0.1. Rules are plotted based on support and \( \chi^2 \) values with color reflecting confidence value (darker shading represents higher confidence value).

For the pos_problem dataset, Figure 4 includes graph-based visualizations of the 39 rules and top 50 rules generated with the intermediate and low thresholds, which demonstrate how different family history problems and rules are highlighted with varying thresholds. For example, the top rule based on \( \chi^2 \) in Figure 4a is \{[High Cholesterol] \} => \{[Hypertension] \} with support=0.17 and \( \chi^2=171.31 \) and in Figure 4b is \{[Ulcers] \} => \{[Heartburn/Reflux] \} with support=0.01 and \( \chi^2=201.64 \).

Figure 5 presents grouped matrix-based visualizations for the 9 and 31 rules generated using the intermediate thresholds for the pos_problem_relation and pos_problem_side datasets respectively while Figure 6 shows all 205 rules generated for pos_problem_degree with the low thresholds in the Gephi (0.8.2) visualization tool. These three sets of rules represent more granular associations in comparison with those from pos_problem and convey the presence of family history problems in particular relatives, side of family (maternal or paternal relative), and degree of relationship (first or second degree relative). While lower ranked, there are several rules including asthma in particular relatives or side of family such as \{[Asthma]_[Brother] \} => \{[Asthma]_[Mother] \} with support=0.03 and \( \chi^2=9.28 \) in Figure 5a and \{[Asthma]_[paternal] \} => \{[Asthma]_[maternal] \} with support=0.01 and \( \chi^2=1.34 \) in Figure 5b. In Figure 6, the highest ranking rule is \{[Arthritis]_[first] \} => \{[Arthritis]_[second] \} with support=0.01 and \( \chi^2=99.84 \) and lowest is \{[Thyroid Disease]_[first] \} => \{[Asthma]_[first] \} with support=0.02 and \( \chi^2<0.01 \).

The reviewed literature sources described several known familial risk factors for pediatric asthma: family history of atopic diseases (asthma, allergic rhinitis, and atopic dermatitis [eczema]) in general as well as in specific relatives (parents, siblings, and grandparents)\(^6\), \(^8\)-\(^10\), \(^38\)-\(^41\). Some studies also reported on the effect of number of relatives (asthma in one or more relatives) as well as sex (male or female relatives)\(^8\)-\(^10\). Asthma co-morbidities include: sinusitis, gastroesophageal reflux disease (GERD), obesity, psychological disturbances (particularly depression and
anxiety disorders), and tobacco use. In addition, conditions reported to be possibly increased with asthma include: hypertension, diabetes, heart disease, arthritis, and cancer. Collectively, the results in Table 3 and Figure 4-6 are consistent with the existing evidence of familial risk factors and co-morbidities for asthma.

**Figure 4:** Graph-based visualization of rules for pos_problem with minimum support of 0.03 and confidence of 0.3 [39 rules] (a) and minimum support of 0.01 and confidence of 0.1 [194 rules; only top 50 shown] (b). In this representation, family history problems and rules are represented as vertices and edges indicate the relationship between problems in rules. The size of the vertex represents the $\chi^2$ value (larger circle for higher value) and color corresponds with support value (darker shade for higher value).

**Figure 5:** Grouped matrix-based visualizations of rules for pos_problem_relation (a) and pos_problem_side (b) using minimum support of 0.03 and confidence of 0.3. The x-axis displays items in the LHS of the rule and y-axis displays items in the RHS of the rule. Circle size and color reflect the strength of a rule based on $\chi^2$ and support respectively.
Discussion

In this study, the feasibility of using structured family history information in the EHR was explored for identifying and assessing interactions among potential familial risk factors for pediatric asthma. The preliminary results highlight the potential of the developed approach for validating known knowledge and suggesting opportunities for further investigation. As reflected in the analyses (Figures 4-6), rules including family history of asthma, allergic rhinitis, and allergies in general, specific relatives, maternal and paternal side of family, and first- and second-degree relatives support what has been reported in the literature. Other rules reflect reported asthma co-morbidities (e.g., Heartburn/Reflux, Depression, and Anxiety Disorders) as well as common chronic conditions in adults (e.g., Cancer, Diabetes, Heart Disease, Hypertension, and High Cholesterol). There is also some evidence of associations for asthma and potentially related conditions (e.g., otitis media) with Migraines and Hearing Loss, which appeared in Figure 6. The findings from this study represent a first step towards further understanding the potential effect of family history of asthma, asthma co-morbidities, and other chronic conditions that may ultimately contribute to informing enhancements to tools for predicting increased risk of asthma in children (e.g., the Asthma Predictive Index that specifies parental asthma among the major criteria).

In performing the case study for pediatric asthma, several next steps were identified for enhancing the knowledge discovery process. Cohort identification was based on documentation of particular ICD-9-CM codes as the encounter diagnosis or on the problem list. Future studies would explore use of other data in the EHR (e.g., medications such as inhaled corticosteroids and clinical notes) and compare the accuracy of these different sources. Additional fields from the family history module in the Epic EHR at the University of Vermont Children’s Hospital as well as family history documented within clinical notes could serve to complement the structured problem and relation fields. For example, as shown in Table 1, the free-text comment field may include problems, relations, or other information that could not be documented in structured format. Existing NLP tools for family history could be adapted to extract information from the comments and notes for subsequent integration and data mining.

Several known issues are associated with association rule mining such as the generation of large numbers of rules that can present challenges for identifying meaningful associations. A related challenge is ensuring that important rules are not missed due to high thresholds (referred to as the “rare item problem”). To address these challenges, a number of algorithms and techniques have been proposed such as generalized association rule mining that involves use of concept hierarchies to generate rules at different levels of granularity. In this study, family history entries...
were analyzed at four levels of granularity where the most general rules were generated from pos_problem, most specific rules from pos_problem_relation, and intermediate rules from pos_problem_side and pos_problem_degree. Next steps include exploring use of existing concept hierarchies for relations (e.g., HL7 Vocabulary for RoleCode that includes almost 150 values organized in a six-level hierarchy) and disease groupings to also enable generalization of problems (e.g., Clinical Classifications Software and PheWAS groups for ICD-9-CM). Different thresholds for support and confidence were used to understand the effect of these constraints on number and content of rules and two sets of thresholds were selected as a demonstration (Figure 2). Further work is needed to determine the balance between number and quality of rules to facilitate interpretation and evaluation.

In interpreting the generated rules, questions arose regarding the appearance of common chronic conditions and whether there may be bias due to documentation practices. Different control populations (e.g., pediatric patients who do not have asthma or have other chronic conditions such as diabetes) could be used to compare family history associations, filter common rules, and thus highlight those that may be unique and relatively more common to the pediatric asthma population. Documentation by different providers or clinics (e.g., primary care vs. specialist) as well as variable EHR user interfaces for family history also warrants further investigation. For example, the top rules generated for neg_problem included negative family history problems that were often associated with encounters in a pediatric orthopedics clinic, speaking perhaps to differences in documentation practices and possibly how family history questions are asked. For the initial validation, a number of literature sources were used to identify known familial risk factors and co-morbidities for asthma. Biomedical literature (e.g., in PubMed/MEDLINE) and other data sources (e.g., public health surveys) could serve as potentially valuable sources for mining and discovery of associations among risk factors for diseases that could complement or be used to validate those generated from the EHR. Next steps also include exploring additional visualization techniques and tools (e.g., R packages for heatmaps) to improve readability and facilitate interpretation as well as conducting more formal evaluations that would involve categorization of rules by clinical experts (e.g., as known/unknown or direct/indirect).

The approach used in this study was designed to be generalizable to other institutions, risk factors, and conditions. Use of open-source technologies (R and Ruby) also provides a flexible, configurable, and extensible framework. Planned extensions to the approach include incorporating standards to promote knowledge sharing and comparison across institutions. For example, the local codes assigned to problems and relations used in this study could be mapped to the Unified Medical Language System (UMLS) Metathesaurus and HL7 Vocabulary for RoleCode respectively. Based on a preliminary mapping, ~93% of the problems could be mapped to UMLS concepts using a combination of MetaMap and manual searches while 73% of the relations could be mapped to HL7 Vocabulary codes. Other next steps include incorporating risk factors documented as part of the social history in the EHR to gain insights to interactions among familial, social, and behavioral factors for diseases such as pediatric asthma.

Conclusion

The widespread adoption of EHR systems has the potential to contribute to enhancing knowledge of interactions among risk factors for diseases. This study demonstrated the use of structured family history information from an EHR to identify pairwise associations representing interactions among potential familial risk factors for pediatric asthma. The preliminary findings support existing evidence and provide guidance for next steps in exploring the use of family history in disease risk assessment.

Abstract

The predictive modeling process is time consuming and requires clinical researchers to handle complex electronic health record (EHR) data in restricted computational environments. To address this problem, we implemented a cloud-based predictive modeling system via a hybrid setup combining a secure private server with the Amazon Web Services (AWS) Elastic MapReduce platform.

EHR data is preprocessed on a private server and the resulting de-identified event sequences are hosted on AWS. Based on user-specified modeling configurations, an on-demand web service launches a cluster of Elastic Compute 2 (EC2) instances on AWS to perform feature selection and classification algorithms in a distributed fashion. Afterwards, the secure private server aggregates results and displays them via interactive visualization.

We tested the system on a pediatric asthma readmission task on a de-identified EHR dataset of 2,967 patients. We conduct a larger scale experiment on the CMS Linkable 2008-2010 Medicare Data Entrepreneurs’ Synthetic Public Use File dataset of 2 million patients, which achieves over 25-fold speedup compared to sequential execution.

INTRODUCTION

High healthcare costs have placed a burden on the federal budget in the United States. Over 90% of Medicare expenditure can be attributed to the management of chronic diseases.¹ However, the quality of care is still far from optimal for many patients, especially those with chronic conditions such as asthma.² While there has long been an interest in lowering asthma readmission rates, most predictive modeling studies for asthma have applied a small number of models and may be limited by small datasets. Fortunately, the rapid adoption of electronic health records (EHRs) in healthcare systems provides an exciting opportunity for researchers to leverage this data for secondary uses such as predictive modeling.

While predictive modeling approaches can aid in the detection of readmissions, the predictive modeling process is tedious and time consuming. Researchers often evaluate many models and compare performance metrics between them. Each model may involve different cohort selection criteria, or different features used in predictive modeling tasks. Furthermore, researchers may elect to evaluate several different algorithms in order to choose the best method for predicting a particular target outcome. These iterative predictive modeling efforts will accumulate and lead to large differences in performance metrics attained when comparing the outcomes of different models. Furthermore, with the tsunami of EHR data we need a more scalable computing infrastructure. Taking the aforementioned drawbacks together, we argue that the traditional predictive modeling pipeline is in need of a major overhaul.

With the rapid adoption of EHR systems in hospitals, predictive modeling will be of major interest in the clinical setting. A number of studies have performed predictive modeling for applications such as asthma readmission prediction in hospitals.³–⁶ However, most of these studies were done using either standalone software products for statistical analysis, or computer code written independently by researchers. Such approaches are often conducted entirely on the researchers’ local computers, and are not scalable with large datasets that are made available as EHR adoption grows rapidly.

Meanwhile, there is evidence that cloud computing can be leveraged in order to support big data analytics on large datasets over a large number of machines in a distributed setting.⁷,⁸ To date, there does not exist a cloud based web service that supports predictive modeling on large healthcare datasets using distributed computing. There
have been some implementations of predictive modeling software. For example, McAulley et al. built a standalone application for clinical data exploration and machine learning. However, the tool was run on local machines and was not deployed on the cloud for easy use by others. The lack of development of health analytics systems on the cloud may also partially be due to the concern of privacy and security of patient data on the cloud.

In addition to the problem with large datasets, researchers often run many iterations of predictive modeling studies before arriving at a desired result. Each iteration may involve changes in the study cohort, features used, and specific machine learning algorithms run. Constantly toggling these parts of the process is tedious and may result in errors. Ng et al. developed the PARAMO system, a predictive modeling platform which constructs a large number of pipelines in parallel with MapReduce/Hadoop. However, PARAMO is built on the user’s own cluster, which is not always available in every clinical institution, and also lacks scalability when faced with large datasets beyond the capacity of their existing cluster. In addition, most pipelines such as PARAMO are difficult to deploy in a clinical setting due to the large expenses required to maintain servers. Therefore, these systems make little to no impact on clinical decision-making.

To help address the limitations of current predictive modeling pipelines, we developed and deployed a hybrid system that combines a secure private server with the cloud-based Amazon Web Services (AWS) Elastic MapReduce platform. The system consists of a web service that runs on a private server in a secure environment for preprocess patient data into feature matrices, and an on-demand AWS web service to perform predictive modeling computations. Note that such a hybrid setup enables security of the patient data and at the same time leverages the scalable computing infrastructure on the cloud. Our system is highly customizable to support various predictive model configurations. Furthermore, the system is highly scalable, as the number of cloud-based machines launched can increase with the size of input data. Finally, the system is cost effective because the AWS Elastic MapReduce cluster is only launched when predictive modeling jobs need to be run.

We applied our platform to a predictive modeling task of identifying patients at risk for asthma readmission using a cohort of patients from the Children’s Healthcare of Atlanta EHR system. As one of the most common chronic illnesses in children, Asthma costs over $56 billion each year, placing a financial burden on the healthcare system. Asthma affects 10.5 million children in the United States annually, and leads to a total of 10.5 million missed school days each year. However, a child whose asthma is properly controlled with education, medication and lifestyle has a better chance of avoiding emergency department (ED) visits as an inpatient. In addressing these issues, care managers want to understand the trends and patterns in the entire patient population. Currently, that is done by grouping patients using diagnosis categories such as Clinical Risk Groups (CRGs) or by risk stratification using risk scores such as clinical risk scores (CRS) for asthma. However, neither approach provides homogeneous patient clusters for purposes of determining targeted treatment protocols. As an alternative, we propose to use our predictive modeling system based on a machine learning strategy to identify patients at high risk for readmission from context-specific information.

In addition to the asthma readmission prediction task, we showed that our system is scalable to large datasets by successfully running a prediction task on the publicly available CMS Linkable 2008-2010 Medicare Data Entrepreneurs’ Synthetic Public Use File (DE-SynPUF) dataset, which includes over 2 million patients.

**METHODS**

In this section we describe the design and implementation of our predictive modeling system.

**General Overview**

The system is composed of two main elements, a persistent web service in a private environment such as a hospital’s internal server and an on-demand web service on a cloud-computing environment such as AWS. The persistent web service constantly runs on a dedicated server, houses raw EHR data, and performs preprocessing of data. Processed data in the form of event sequence files are sent to the predictive modeling module, which is powered by an on-demand web service such as an AWS Elastic MapReduce cluster. Once the predictive modeling module is finished, the results are aggregated and displayed to the user in the performance analysis module running on the persistent web service. Figure 1 illustrates the key components of our system.

**Preprocessing**

Data from the EHR are first converted into event sequence files to be used as input to the predictive modeling module. The event sequence files are in the form of text files where each line represents one distinct event from the database. Each record is represented by a tuple in the format \((\text{patient, event, timestamp, value})\), where patient, event, timestamp and value represent the patient ID number, event name, date and time of the record, and a value for the event, respectively. In the case of binary events, such as medication and diagnostic events, the value for a tuple
is set equal to 1. In the case of events that are normally associated with numerical values, such as lab values, the value for the tuple is set to the numerical value that is present in the record. In the case of categorical events, such as gender recorded in an admission, the value for the tuple is set to the alphabetical value (i.e. ‘F’ and ‘M’ for gender) from the record. The final event sequence files are used as inputs to the predictive modeling module.

Instead of using the raw information such as actual patient IDs and ICD-9 codes, the data in event sequence files are further transformed into internal coded values on the persistent web service before being uploaded to the on-demand AWS web service. In particular, patient IDs and event names can be hashed into internal IDs. Thus, the raw patient information would not be used in the predictive modeling processes running on the cloud for security considerations. After the predictive modeling module is finished, specific patient ID numbers and event names may be decoded on the persistent web server before running the performance analysis module on the dedicated server.

**Predictive Modeling Module**

The predictive modeling module consists of several stages. First the cohort construction and feature construction stages are conducted. Next, cross validation stages comprised of feature selection followed by either classification or regression are run. We call a concrete step in one predictive modeling process a task. Examples of tasks include constructing diagnoses features, or building a logistic regression classifier on a specific training set. We organize all those tasks into different computation stages: cohort construction, feature construction, cross validation data splitting, feature selection, classifier training and classifier testing. Note that each stage corresponds to one or many computational tasks. All of these tasks occur on the on-demand web service, which is implemented with AWS Elastic MapReduce.

The predictive modeling module launches a new AWS Elastic MapReduce cluster consisting of multiple EC2 instances for each analysis workload. The predictive modeling module aggregates all computational tasks from all stages of predictive modeling process and schedules them to run in parallel on the provisioned AWS cluster. The user is allowed to choose the number EC2 virtual machine instances and the types of machines to use in the MapReduce cluster. Next we introduce those computation stages in more details.

**Cohort construction:** Once event sequence files are uploaded to the on-demand web service, the user can specify a set of filtering criteria that can be used for constructing cohorts (Figure 2A). A user can define the patient selection criteria for cases and controls. For example, for an asthma readmission prediction study, the user may define the case patients by inputting readmission as the target event to predict. Patients who have the target event will be regarded as cases and others as controls.

After user defines the target event to predict, the user can further narrow down the cohort to study by specifying conditions. For example, user may require all patients in cohort should have at least 3 inpatient events. After the user selects case cohort inclusion conditions, the user may want to balance the number of cases and

---

1 See http://aws.amazon.com/ec2/instance-types/ for more details
controls via matching (Figure 2A). In this situation, the user may elect to select a limited number of matched controls using a matching algorithm based upon patient similarity metrics or propensity scores. Currently, a simple case-control matching algorithm is implemented, which selects control patients that have identical or numerically similar values for the matching criteria as the case patients.

**Feature construction:** Features from the event sequence input data may be aggregated depending on user preferences and study design. The feature construction module allows the user to specify a method of aggregation for each event type with respect to its values for each patient. The aggregation methods include mean, sum, count, and latest. Mean and sum are the mean and sum of the values across all certain events for a given patient. Count is the number of times the feature occurs as an event. Latest is the value for the feature at the most recent occurrence. Figure 2B shows a screenshot of the feature construction module.

During the feature construction phase, besides the feature matrix, other entities will also be computed and stored for later usage. For example, feature value statistics will be used for the performance analysis module on the persistent web service. Feature value statistics we collect include percentage of cases/controls who has certain events and distributions of feature values within cases and controls.

**Feature selection:** The predictive modeling module runs a combination of feature selection and classification tasks. Since EHR data is often high dimensional in nature, some features may have a large amount of missing or noisy information. Feature selection is used to filter out these features, which should not be considered for predictive modeling. The feature selection algorithms implemented include raw features, the Chi-square feature selection, analysis of variance (ANOVA) F-value based feature selection, and false discovery rate based feature selection. The raw features method uses all constructed features from the data. The Chi-square method uses a Chi-squared test to evaluate p-values for each feature with respect to the target labels. A smaller p-value indicates a more predictive feature. For example, user may choose to select features with p-values less than 0.05. Likewise, the analysis of...
variance (ANOVA) F-score method applies an ANOVA test to each feature with respect to the target labels. The false discovery rate method selects features for being correlated with the target labels using the Benjamini-Hochberg algorithm.17

**Classification and regression:** We included all classification algorithms from the Python scikit-learn18 package, including logistic regression (LR), support vector machine (SVM), k nearest neighbors (KNN), random forest (RF) and beyond. The user is able to specify parameters for each classifier, for example the type of kernel for SVM, the number of trees for RF, the number of neighbors and the distance metric for KNN, and the method of regularization and type of optimization in LR. Similarly, all regression algorithms from the scikit-learn package are also included.

**Cross validation:** In the case of classification or regression problems, cross validation is run for each possible pairing of feature selection method followed by classification or regression methods. The user is able to set the number of folds in cross validation and number of iterations to run cross validation (Figure 2B). For each fold of cross validation, feature selection is first run on the training folds of the dataset. The selected features are used in the classification algorithm to be run. The system will figure out the set of tasks to run and their dependencies. For example, on a given fold of cross-validation, classifier C’s input depends on the output of feature selector S of the same fold, thus the system runs C after S. For other tasks independent from C or S, the system could schedule them running in parallel with C and S.

**Parallelization:** As described previously, our system runs on an on-demand AWS Elastic MapReduce cluster. The system achieves speed and scalability from two levels of parallelization. The first level is within-task parallelization, which means a predictive modeling task itself is implemented using big data parallel processing techniques. For example, cohort construction and feature construction are implemented using Spark19. Thus, different features will be constructed in parallel. Another level is between-task parallelization. All tasks derived from the predictive model configuration form a dependency graph, and the system schedules tasks in topological order. A task will be ready to run whenever its dependencies finish. For example, testing of a classifier could be scheduled to run when the training of the given classifier finishes. All tasks whose dependencies satisfied could run in parallel. For example, if both classifier A and B depend on feature selector C, A and B can start running simultaneously when C finishes. The degree of parallelization will be determined by the capacity of the cluster, which is usually measured by total number of CPU cores and total memory available. All the scheduling and execution are done using Hadoop and Cascading running on AWS MapReduce clusters.

Once all tasks are finished, the system collects and aggregates the results from all clusters’ distributed file systems. The results are sent to the performance analysis module on the persistent web service.

**Performance Analysis Module**

The final module of the system is the performance analysis module on the dedicated server. The results from all classifiers run in the predictive modeling module’s MapReduce service are collected, aggregated and stored in a MongoDB database running on the persistent web service. The performance metrics calculated include area under the receiver operating curve (AUC), positive predictive value (PPV), sensitivity, F1 score, accuracy and Matthews correlation coefficient. The web service retrieves the performance metric data from the MongoDB database and displays results to the user in an intuitive interactive interface. Figure 2C shows a screenshot of the webpage displayed to users.

**RESULTS**

Next we describe the results from the application of our predictive modeling platform to an asthma readmission task.

**Asthma Prediction Task Experiment Setup**

The study involved a cohort of 2,967 inpatient pediatric asthma patients from the Children’s Hospital of Atlanta (CHOA). There were 1,493 patients who had at least one readmission for asthma treatment, and 1,474 patients who did not have any readmissions. Data for inpatient events representing emergency department initial visits and readmission visits were used. Table 1 showcases general patient characteristics of the study cohort.

To run the preprocessing and performance analysis modules, we hosted the persistent web service on dedicated server running the Ubuntu 14.04.1 LTS operating system, with 24 Intel Xeon 2.6GHz processors (six cores each) and 256 GB of RAM. An on-demand web service was launched in order to run the predictive modeling module. The on-demand web service consisted of an AWS Elastic MapReduce cluster consisting of 1 master m3.medium EC2 instance and 20 slave c3.xlarge EC2 instances.

**Feature Construction:** We preprocessed the data set and obtain 5,728 unique patient visits. Each visit has a readmission label showing that whether or not the visit has led to one or more visits within the next 12 months.

We constructed six groups of features: demographic features, diagnosis features, medication features, procedure features, and visit features. The demographic, diagnosis, medication and procedure features are
categorical features while the lab and visit features are numeric features. Table 1 shows descriptions and example values for features in each group. We converted the categorical features to 1-over-K binary code representations. For example, the feature “race” has five distinct categories: White, Black or African American, Asian, American Indian or Alaska Native, and Others. If a patient belongs to the category white, his or her “race” will be represented by a 5-dimensional feature vector \([1,0,0,0,0]\). The diagnosis and medication features were binary features, where a value of 1 indicates that an event occurred for that feature and a value of 0 indicates that an event did not occur. Furthermore, we convert the numeric features to z-scores. Taking a 40-month-old patient for example, the z-score of feature “age” will be -0.91 given that the average and standard deviation of “age” in our cohort are 100.10 months and 66.13, respectively.

**Cohort Construction:** We obtained a cohort of 1,493 unique patients with asthma readmission within one year after being discharged and 1,474 unique control patients without readmission matched on age in month and gender. We use a 1919-dimensional feature vector to represent each patient. We summarize the statistics of demographics of the cohort in Table 2.

Table 2: General patient characteristics of the study cohort. Demographic features are shown for all patients, as well as for patients with at least 1 readmission event, and patients without any readmission events.

**Feature selection:** We performed feature selection using four separate methods: raw features, ANOVA F-score feature selection, Chi-square feature selection, and false discovery rate (FDR) feature selection.

**Classification:** We formulated the asthma readmission prediction as a binary classification problem where the two target labels are defined as follows:

1: at least one readmission within 12 months of any inpatient visit
0: otherwise

We applied four commonly used classifiers: logistic regression (LR), linear support vector machine (linear SVM), K-nearest neighbor (KNN), and random forest (RF). We used stochastic gradient descent with L2 regularization for the logistic regression, set K=1 and use Euclidean distance for KNN, used a linear kernel with c=1 for SVM, and used 100 trees for RF.

**Performance analysis:** We partitioned the patients into training and testing cohorts in a 3 times 5-fold cross validation process, meaning cross validation was run for 3 iterations. For each fold, we first performed feature selection and then trained the model on the training set (80% of the entire data) using the selected features. Afterwards, we evaluated the model performance on the testing set (20% of the entire data). We used the following evaluation metrics: a) area under the receiver operating characteristic curve (AUC); b) positive predictive value.

---

ii There is a larger number of cases than controls because multiple cases can match to the same control patient.
(PPV); c) sensitivity; d) F1 score; e) accuracy. To calculate the final value for each performance metric, we find the mean of the means of each metric across all iterations.

**Asthma Experiment Results**

**Feature selection:** Of all of the feature selection methods, the false discovery rate (FDR) method achieved the best overall performance with AUC 0.69, PPV 0.69, sensitivity 0.46, F1 score 0.55, and accuracy 0.77. Table 3 shows the top predictive features selected by the FDR feature selection method in all 10 folds. Six out of the 10 features were verified by pediatric clinicians to be possible indicators for asthma readmission (highlighted in Table 3). Two of the features, the medication *fluticasone-salmeterol* and the lab *total immunoglobulin E (IgE)*, are known to be strong indicators for asthma readmission. The *fluticasone-salmeterol* feature is present in 15% of all cases while present in only 8% of all controls. This result is clinically meaningful because *fluticasone-salmeterol* is commonly prescribed in more severe asthmatic patients. The *total immunoglobulin E (IgE)* lab value is 565 IU/mL in cases and 258 IU/mL in controls. This result is clinically meaningful as well, since more severe asthmatic patients tend to have higher values for IgE, a marker indicating sensitivity to allergens.23

Table 3: The top 10 most predictive features selected by univariate feature selection based upon ANOVA F-value. Features verified by clinicians to be possible indicators for asthma readmission are shown in bold print.

**Classification:** We performed cross-validation to choose the appropriate number of features that gives the best performance. Cross validation was performed on each possible combination of feature selection algorithm and classification algorithm. For each feature selection method, we collected all features that met the feature selection criteria. These features were used as predictive features in the classification tasks. Table 4 shows the performance of the linear SVM classifier while using different feature selection methods and raw features. The feature selection method with the highest average of all performance metrics was determined to be the one with the best performance.

Table 4: Performance of linear SVM with different feature selection algorithms. Feature selection algorithms used include: ANOVA F-value, Chi-square, false discovery rate, false positive rate, and all features. Values shown are mean (standard deviation) across all iterations and folds of cross validation.

The results of the four different classifiers using the feature selected by the FDR feature selection method are shown in table 5. There was variability in performance of the classifiers. Linear SVM achieved the highest AUC (0.69). Logistic regression achieved the highest sensitivity (0.99), while random forest achieved the highest PPV (0.89), F1 score (0.74), and accuracy (0.86).

It is important to consider these results in the context of the particular application. For the asthma readmission prediction problem, the SVM, logistic regression, or random forest methods may all be considered effective models based upon different use cases. In cases where sensitivity may be important (e.g., detecting high risk patients who may need urgent care), logistic regression may be the best model. In cases where positive predictive value may be
important (e.g., when treatment for positively predicted patients is expensive, and financial resource allocation is important), then random forest may be the best model.

Metrics reported include area under the receiver operating characteristic (AUC), positive predictive value (PPV), sensitivity, F1 score, accuracy and Matthews correlation coefficient. Values shown are the mean (standard deviation) across all iterations and folds of cross validation.

System Scalability
To demonstrate the scalability of our system, we ran our system on a much larger dataset, a set of 2.1 million patients from the CMS Linkable 2008-2010 Medicare Data Entrepreneurs’ Synthetic Public Use File (DE-SynPUF), a publicly available synthetic dataset. It contains approximately 300,000 different kinds of events from the patients. Thus, there were about 2.1 million patients and 300,000 features in the input dataset. The raw event sequence input file size is 6.88GB. We created a predictive modeling workload with more than 3000 tasks. The feature selection and classifier settings are almost identical to those used in the asthma readmission prediction task. The on-demand web service is composed of 10 r3.2xlarge AWS EC2 virtual machines. Figure 3 shows the timeline of parts of the task run and the amounts of time spent. the CMS data. The entire running time of the pipeline workflow is about 3 hours. To serve as a baseline, we ran all the tasks sequentially on a single server of the same machine configuration to calculate the total running time of a sequential run. We find that our system achieves a 36-fold speedup over the baseline sequential running time. Note that the feature construction step is only conducted once, while the data splitting, feature selection, model training and model testing steps are done for each iteration of cross validation.

**Figure 3:** Timeline of modules run and elapsed time. The data-splitting, training and testing times refer to the run times for each respective step of cross validation. Times are shown in seconds (s).

**DISCUSSION**
We have developed a cloud based system for clinical predictive modeling. Our system is the first of its kind to date, and leverages Amazon Web Services’ Elastic MapReduce technology to run distributed feature selection and classification jobs in a time efficient manner.

**Challenges in Privacy and Security**
While the usage of the cloud is relatively new, many users are already using the cloud for hosting personal health information (PHI).\(^1,7,24-26\) In the case that the users are unwilling to store EHR information into the cloud, our system architecture can be used in such a way that preprocessing of data can be performed on the persistent web server, and PHI can be mapped to codes. For example, all information including patient ID numbers and medication, procedure, lab and diagnosis names may be hashed and mapped to different values such that the raw data were not uploaded to the cloud based system.

Our system mitigates potential concerns regarding privacy and security of healthcare data. However, we also recognize the heuristic nature of our approach, and in the future we plan to conduct more focused studies on privacy consideration using the cloud in an effort to provide a more theoretical guarantee of privacy.

CONCLUSION

We have proposed and implemented a hybrid version of predictive modeling system, which combines a private dedicated instance and public cloud computing services. In this system, raw EHR data are converted into standardized features written into event sequence data files via persistent web services on the private server. The de-identified event sequence files are uploaded to an on-demand web service via Amazon Web Services, which subsequently constructs cohorts and features and schedules a series of distributed predictive modeling tasks using big data systems such as Spark and Hadoop. The results of the predictive modeling tasks are collected and displayed to the user in a highly intuitive, interactive user interface on the private server.

We applied our system to a specific task of prediction for pediatric asthma readmission using a cohort of case patients with asthma readmission and matching control patients. The predictive modeling module was successful in the prediction task through a 5-fold cross validation scheme. The system predicted patients at risk for 12-month asthma readmission with an AUC of 0.69.

We plan to improve upon the system by expanding the suite of cohort construction strategies, feature selection algorithms and classification algorithms. Furthermore, we plan to add functionality for testing multi-class classification tasks (e.g., to be used for detecting multiple types of readmissions).

Abstract

Complexity in clinical workflows can lead to inefficiency in making diagnoses, ineffectiveness of treatment plans and uninformed management of healthcare organizations (HCOs). Traditional strategies to manage workflow complexity are based on measuring the gaps between workflows defined by HCO administrators and the actual processes followed by staff in the clinic. However, existing methods tend to neglect the influences of EMR systems on the utilization of workflows, which could be leveraged to optimize workflows facilitated through the EMR. In this paper, we introduce a framework to infer clinical workflows through the utilization of an EMR and show how such workflows roughly partition into four types according to their efficiency. Our framework infers workflows at several levels of granularity through data mining technologies. We study four months of EMR event logs from a large medical center, including 16,569 inpatient stays, and illustrate that over approximately 95% of workflows are efficient and that 80% of patients are on such workflows. At the same time, we show that the remaining 5% of workflows may be inefficient due to a variety of factors, such as complex patients.

Introduction

The success of an electronic medical record (EMR) system implementation and its subsequent adoption by users is contingent upon the initial design and refinement of workflows in the healthcare organization (HCO)¹,². The appropriate design and management of workflows can significantly improve efficiency of clinical treatment³,⁴, care quality⁴, patient safety⁵, and care decisions⁶. Yet, despite their potential, workflows can be quite complex⁷, creating barriers to EMR system utilization⁸. This can ultimately lead to inefficiency in diagnoses, ineffectiveness of treatment plans, and uninformed management of an HCO. To mitigate workflow complexity in EMR systems, it has been suggested that HCOs design workflows to optimize business processes or manage the complexity of current workflows, rather than rely upon current workflows¹,⁷,⁸,⁹.

To enable such strategies, various approaches have been developed to measure the gap between the workflows defined by an HCO and the actual processes followed by individuals in a clinical setting. In general, for the gap analysis approaches, the HCO workflows are compared to the expectation of experts in the organization, as learned through surveys, interviews or observational data collected in the physical healthcare setting⁷,⁸,¹²,¹⁴,¹⁵,¹⁶. Application of these methods requires a substantial exertion of manual effort because it requires invasive interviews and patience while observing the interactions between care providers and patients. As a result, this type of approach is often limited to specific areas of clinical care. Furthermore, these methods only measure the gap between the organization’s workflows and the expectation of care providers. This neglects the influences of EMR systems on the utilization of workflows, which could be leveraged to optimize workflows facilitated through the EMR systems.

By contrast, most recent approaches model workflows by mining data recorded in the EMR system. This type of strategy considers the influences of EMR systems on the utilization of workflows, but it only models the patterns of care paths, and neglects the efficiency management of workflows⁹-¹¹.

Good management of workflow efficiency can improve quality of clinical care and reduce costs of patients¹,¹. By providing HCOs with such knowledge of workflows, we anticipate healthcare administrators will be able to optimize the efficiency, as well as minimize the complexity of workflows in a more productive manner. For instance, imagine that an HCO administrator learns a particular clinical process tends to require a long duration in time, but that the process has a large variance in its duration across the enterprise. Based on this knowledge, they can investigate the reasons behind such long waiting times and variation. In this paper, we introduce a framework to model clinical workflows at two levels of granularity and categorize these workflows according to their efficiency. To the best of our knowledge, this is the first approach to automatically learn and categorize workflows according to their duration.

416
Background
The past several years have witnessed a number of investigations into modeling and characterizing the workflows associated with clinical practices. As alluded to earlier, we characterize these investigations, and the approaches upon which they are based, into two classes. These classes are dependent upon the methods of data acquisition and analysis that are invoked: i) physical observation studies (in the clinic) and ii) virtual observation studies (data in the EMR). Here, we take a moment to review representative research from both categories and illustrate the relationship with our own approach.

Workflows Based on Physical Observations
Observation-driven studies often rely on manual data collection approaches, such as observations and interviews. One such example was presented by Unertl and colleagues, which analyzed direct observations and interviews in hospitals to understand workflow and information flow in the care of chronic diseases. Similarly, Ramaiah and colleagues designed surveys consisting of questions, interviews of care providers and patients to discover workflows associated with time delays in the HCO. In another setting, comparative data were collected from the operating room and statistical analysis was performed with respect to gains in efficiency. The ultimate goal was to justify the need for reorganizing clinical workflow to increase throughput in the operating room. In other work, ethnographic observation and interview data were applied to study the evolution and management of medical errors.

Workflows Based on Virtual Observations
Modern studies are increasingly turning to EMR-related data because they can enable large scale analytics at a low acquisition cost. While more comprehensive surveys exist about workflow mining in the EMR, we briefly examine investigations relevant to our approach.

In one study, Zhang and colleagues utilized EMR usage logs to model patients’ flow in the healthcare system. After learning patterns of patient record usage, deviations from the average workflows were detected and promoted for investigation as either undocumented policies or misuse of the EMR system. Similarly, another study employed sequence alignment methods to derive a consensus workflow and automatically detect outliers from surgical activity logs. Other studies have focused on contrasting treatment differences for certain diseases. For instance, Mans and colleagues studied stroke care by applying process mining to clinical data. They additionally compared the pathways from disparate healthcare systems and various types of patients. Most recently, Partington and colleagues focused on cross-hospital process mining and performed a comparative analysis by leveraging a combination of administrative and clinical data. This investigation yielded detailed insights into patient care and hospital budget pressures.

Methods
We provide a framework to 1) learn workflows and 2) categorize the workflows into four general types according to the length and variation in their temporal duration. For reference purposes, we summarize the common terms and notation used in this paper in Table 1.

**Event.** An event corresponds to the smallest granularity associated with a workflow. This corresponds to an action invoked by an EMR user over a patient’s medical record at a certain time. For instance, a user, acting as a pathologist, can initiate an event by accessing a patient record to request a lab test. Alternatively, another user, acting as a primary care provider, can initiate an event by accessing a patient record to approve a request to refill a medication.

**Sequence.** A patient sequence consists of a series of ordered events that represents an episode of a patient process. For example, an ordered series of events could be: a user, acting as a physician requested a lab test for a patient → a laboratory user uploaded a lab test result for the patient → the lab test results were returned to a care provider in a physician office → a registered nurse provided customer service support to the patient in response to an inquiry about the lab test results. We assume we are provided with m events that are classified into n patient sequences.

**Block.** A block is an ordered series of events that have strongly ordered relations with each other. For example, if the relation between an event Rehab Service Clinician and another event Rehab Quality Audit is strong in a way we will define precisely below, then Rehab Service Clinician → Rehab Quality Audit belongs to a block. A block represents a specific stage of a patient process, and a patient sequence consisting of events can be represented using the corresponding blocks. For instance, imagine there are two blocks [Primary Care Physician → Laboratory Tester] and [Physician Office Care Provider → Primary Care Staff Nurse]. Then, the earlier patient sequence example (with four
events) can be represented using these blocks to express a specific stage of a workflow corresponding to the four events.

**Topic.** A topic consists of a set of blocks, which together represent the main processes associated with a patient type. For example, imagine there is a group of patients with the conditions Urinary Tract Infection, Other Specified Retention of Urine, and Unspecified Essential Hypertension. Then a topic consisting of the following blocks may characterize this group: [Advanced Practice Clinician – CPOE → Physician Office], [SN-OR RN SC → Patient Care Assistive Staff], [Physician Office → Advanced Practice Clinician – CPOE], [OR RN SC-Primary → Primary Assistive Staff], [Unit Secretary → Rehab PT, Respiratory → SN-RN/Customer Service], and [SN-RN/Customer Service → NMH Physician Hospitalist-CPOE].

We learn workflows at a fine granularity, in the form of blocks of events, and a coarse granularity, in terms of topics of blocks. Representation at the block-level characterizes the stage of a patient process. By contrast, representation at the coarse-grain characterizes different types of patient processes. Fig. 1 shows an example consisting of 4 models to learn workflows at the block- and topic-level. These are formalized in the Workflow Mining Algorithm (WMA) depicted in Fig. 2.

#### Figure 1. Generation of fine-gained (blocks) and coarse-gained (topics) workflows from patient sequences.

1. **Event Relation Model (ERM):** Measures relations between events according to the patient sequences. The details of relation measurement are depicted in steps 1 through 5 of WMA.

2. **Block Generation Model (BGM):** Generates blocks of events according to the relations of events and patient sequences. The details of block generation are described in steps 6 through 19 of WMA.

3. **Block Relation Model (BRM):** Measures the relations between blocks according to the common events they contain. The details about measurement are in steps 20 through 22 of WMA.

4. **Topic Generation Model (TGM):** Generates topics of blocks to represent a similar type of patient processes. The details are depicted in steps 23 to 26 of WMA.
We introduce these models in detail in the following sections on workflow generation at the block- and topic-level.

**Block-level Workflows**

First, we generate event blocks (i.e., workflows at the block-level) according to steps 1 through 19 of WMA. A workflow at the block-level aims to characterize the efficiency of a stage of a patient process. In this work, we aim to learn four types of blocks:

1. **Stable Efficient Blocks (SEB):** Have short average duration with small variance across the patient population.
2. **Unstable Efficient Blocks (UEB):** Have short average duration with large variance across the patient population.
3. **Stable Inefficient Blocks (SIB):** Have long average duration with small variance across the patient population.
4. **Unstable Inefficient Blocks (UIB):** Have long average duration with large variance across the patient population.

We anticipate that the categorization of blocks into these types can assist HCOs in speeding up the discovery of (in)efficient blocks and refine their policies accordingly. For instance, imagine the block [Radiology Mgr/RC → Attending Physician/Provider] exhibits a large variance in its duration, such that it requires less than 1 hour for one patient, but 240 hours for another patient. Our model could promote this block to administrators for investigation.

We infer blocks from the event logs generated by EMR systems. This is because EMR-facilitated workflows, and the utilization logs in particular, do not necessarily follow the exact order of events in the physical world. For instance, in the real world, the order of events may be $e_1 \rightarrow e_2$, but in some cases, the order recorded by an EMR may be $e_1 \rightarrow e_k \rightarrow e_2$. To relax the order relations of events, we consider relations within a sliding time window. Specifically, we assume that if an event and its following events are within a window of size $\alpha$, the order relations holds, but the strength of the relation is proportional to their distance. We measure the order relation between a pair of events within a sequence as:

$$\text{Event}_{\text{relation}}(e_i,e_j) = \begin{cases} \frac{1}{D_{(p(e_j) - p(e_i))^2}} & (0 < p(e_j) - p(e_i) \leq \alpha) \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

Where $p(e_i)$ is the position of the event $e_i$ in a sequence. The position of the first event of a sequence is set as 1, and the position of the last event of a sequence is set as the length of a sequence. The relations of events are incrementally measured over all of the sequences (as depicted in steps 1 through 5 of WMA). As a consequence, this type of relation considers the ordinal distance between the events and their frequency in the patient population. When we set $\alpha$ to 1, the relation between $e_1 \rightarrow e_2$ is 4 $(1+1+1+1)$ accumulated from sequence $s_1, s_2, s_3,$ and $s_4$ respectively (as shown in Fig.1(b)).

To represent each stage of a patient process via temporal patterns, we infer event blocks through relations of events. The generation of such blocks is shown in steps 7 through 19 of WMA. We assume that, for a sequence of events, if an event has a strong relation with the following events, then they should be grouped into a block. Since the relations of events are already considered in the sliding time window, we only consider the immediately following neighbor in block generation. As shown in steps 10 through 13 of WMA, if the relation of every neighboring event is within a range of $[\beta_1, \beta_2]$, these events are included in a block. The lower bound for the range is applied to filter out weak relations, whereas the upper bound filters highly frequent relations (like stop words, “a”, “of”, or “the” in natural language processing). The end of a block is realized when the relation between an event and its neighbor is outside of the range. For instance, when $\beta_1 = 2$ and $\beta_2 = 4$, sequence $s_1 \rightarrow e_1 \rightarrow e_2 \rightarrow e_3 \rightarrow e_2 \rightarrow e_4$ (shown in Fig.1(a)) generates two blocks $e_1 \rightarrow e_2$ and $e_3 \rightarrow e_4$ (shown in Fig.1(c). This is because the event relations of $e_2 \rightarrow e_2$ and $e_2 \rightarrow e_3$ occur only once, which is below the lower bound threshold of 2.

To evaluate and characterize the time efficiency of blocks, we need contextual information, such as the duration of a block or the reasons for each event in a block. Note, a block can appear multiple times in different patient sequences, such as when $b_{1} \rightarrow e_1 \rightarrow e_2$ exists in $s_1, s_2, s_3,$ and $s_4$. As such, an event block can have multiple reasons and time durations. For example, if $e_1$ happens at 9:00am, and the following event $e_2$ happens at 10:00am in sequences $s_1$, then the time duration for $b_1$ in $s_1$ is 1 hour.

We summarize the efficiency of a block using several basic statistics. Specially, we compute the duration and variance for a block as the average and standard deviation over all occurrences in the patient population. For example, if the time duration of block $b_1$ in the four sequences is 1, 2, 1, and 1.5 hours, respectively, then the average time duration is 1.375 hours and the variance (standard deviation) is 0.4787 hours.
Figure 2. Pseudocode for the algorithm to generate workflows at the block- and topic-level.

**Topic-level Workflows**

A workflow at the block-level only provides a description for a particular stage of a patient process. However, it neglects the relations between blocks within a patient process. To do so, we summarize collections of blocks using a topic modeling strategy (e.g., latent Dirichlet allocation (LDA))\(^{18,19}\), a popular approach to learn latent concepts from a corpus of documents. In our setting, this corresponds to learning a set of latent workflow patterns to represent patient sequences. Conceptually, patient sequences can be thought of as documents, where the event blocks constitute a vocabulary and the specific event blocks assigned to a patient’s sequence are the semantic ideas derived from the vocabulary.

To learn topics, we begin by generating the set of unique blocks. We then represent each original patient sequence \(s_i\) as a new sequence \(s'_i\), consisting of blocks instead of events (step 15 of WMA). For instance, Fig.1(d) depicts 6 unique blocks generated from Fig.1(c). Now, to infer topics of terms (i.e., blocks), we need to prepare the documents (i.e., patient sequences). Here, a term is a block and a document is a patient sequence \(s'_i\) that consists of a series of blocks. While the events within a block are ordered, the order is not necessarily consistent with the real world. As such, we group the blocks associated with similar sets of events. In many respects, this can be thought of as creating a set of synonyms in a vocabulary.

To discover synonyms of blocks, we measure the similarity using the Jaccard coefficient between the blocks (as invoked in step 21 of WMA):

\[
Block_{relation}(b_i, b_j) = \frac{\text{set}(b_i) \cap \text{set}(b_j)}{\text{set}(b_i) \cup \text{set}(b_j)}
\]

where \(\text{set}(b_i)\) corresponds to the set of unique events in a block. Note that this function ranges from 0 (no relation) to 1 (perfect relation). For instance, the relation between block \(b_1\) and \(b_2\) (as shown in Fig.1(d)) is 1 (as shown in Fig.1(e)).
As described earlier, we want each patient sequence, including the synonyms of its blocks, to improve the quality of learned topics through the LDA model. We use Equation 3 to represent a patient sequence using its blocks, along with their synonyms, as:

\[
SB_{relation}(s_i', b_j) = \begin{cases} 
  1 & b_j \in s_i' \\
  1 & b_j \notin s_i' (\exists b_k \in s_i', R_{relation}(b_k, b_j) = 1) \\
  0 & \text{otherwise}
\end{cases}
\]  

(3)

We generate a matrix \( R_{s_i' \times B} \) to represent the relation between a sequence \( s_i' \) and a block \( b_j \) (steps 23 through 25 of WMA). For instance, \( s_i' \) has block \( b_1 \) and \( b_4 \) (as shown in Fig.1(c)), but \( b_1 \) has synonyms \( b_2 \) and \( b_3 \) according to Equation 3. As such, \( s_i' \) is represented by blocks \( b_1, b_2, b_3, \) and \( b_4 \) (as shown in Fig.1(f)). The matrix \( R_{s_i' \times B} \) serves as the input to the LDA learning process (step 26 of WMA).

A topic consists of a probability distribution over a set of blocks as shown in Fig.1(g). The larger the probability of a block, the more this block is representative of the topic. At the same time, the patient process can be characterized by inferred topics as shown in Fig.1(h).

Results

We evaluate our framework on four months of inpatient event logs generated by the Northwestern Memorial Hospital (NMH). In this dataset, an event corresponds to a chart access, each of which is associated with the user and the user-designated reason for the access. It should be noted that the initial reasons selected by a chart user during the hospitalization of a patient persists throughout the hospitalization. There are 1,138,317 total events distributed over 16,569 patient processes. These events were generated by 144 user roles with access to 142 reasons. Additionally, each patient is associated with a set of ICD-9 codes assigned after discharge. The total number of unique ICD-9 codes for this set of patients is 4,543.

To apply WMA, we need to set three parameters: i) the sliding window size \( \alpha \), ii) the event relation thresholds \( \beta_1 \) and \( \beta_2 \), and iii) the number of topics for the LDA model. We set \( \alpha \) to the average number of events that transpired during a 24 hour window. This corresponded to 3 events. \( \beta_1 \) was set to 50 because smaller values led to an extremely large number of blocks (over 100,000), which suggested a substantial amount of noise. \( \beta_2 \) was set to 500 because, at this point, the only events in the resulting blocks corresponded to either: 1) Physician-CPOE, 2) Residence, 3) Patient Assistive Staff, 4) Patient Care Staff Nurse, 5) Respiratory, and 6) Unit Secretary. These extremely frequent blocks limited the generation of meaningful blocks and, thus, we removed these from further consideration. For the LDA model, we set the number of topics according to topic similarity instead of perplexity, based on a previous study\(^{19}\). In doing so, we searched for a model that minimizes the workflow topic similarity, measured as the cosine similarity. We set the number of topics as 15, 20, 25, 30, and 35 respectively, and calculate the corresponding topic similarity in each setting. The topic similarity was minimized (0.0033) when the number of topics was set to 25. Given these parameters, WMA generated 22,442 event blocks and 25 topics of blocks.

In the remainder of this section, we first show the block- and topic-level efficiency results. To illustrate the results at each level, we then provide a case study with respect to the learned workflows.

Block Types

For each block, we record the average and variance in time duration. Figure 3 depicts the 22,442 blocks as a function of these concepts. We partition this space, based on their length and stability, into the four types mentioned above. To do so, we partitioned the system using thresholds of an average length of 100 hours and a variance of 100 hours. According to this split, 94.7% of the blocks are in the SEB area (i.e., short duration with low variance). This suggests that the HCO mainly manages inpatients associated with short processes.

At the same time, this finding implies that approximately 5% of the blocks are of potential concern. Among the remaining blocks, 70% correspond to SIB (i.e., long duration with low variance), 22% correspond to UIB (i.e., long duration and long variance), and 8% correspond to UEB (i.e., short duration and large variance). It is possible, however, that these blocks are artifacts of an insufficient amount of evidence to draw meaningful conclusions. To assess this issue, Figure 4 provides a frequency analysis for all of the blocks as a function of their average duration and variance. Clearly, the frequency of the efficient blocks (i.e., SEB, UEB) is substantially larger than the inefficient blocks (i.e., SIB, UIB). In most cases, the frequency of SIB and UIB blocks is small (around 2~3), which indicates they are not popular in the management of inpatients.
Block Type Case Studies

To gain a deeper appreciation of the different block types, we provide examples of UEB and UIB in Table 3. Block B1 belongs to UEB and has 6 unique reasons associated with it. Its reason R1 is associated with two significantly different durations. The first is less than 1 hour, while the other is 240 hours. The same phenomenon occurs for the reason R4, which has a duration of less than 1 hour and another of 160 hours. These phenomena illustrate how a block with the same chart access reason, can exhibit significantly different durations. They indicate that, though a block encompasses the same transitions between reasons, the time allotted for doing so may be significantly different. This may stem from a number of complications, such as varying patient symptoms and purposes for the hospitalization, the urgency of imaging needs, the ability of some attending physicians to rely on residents in training to access charts for them and provide relevant updates, the resource allocation strategies of HCOs, or the workflow timing of chart access by care providers.

Table 3. Examples of UEB and UIB block types.

<table>

<td>[NMPG MD → CPOE → NMPG APRN → NMPG MD – CPOE]</td>
<td>203</td>
</tr>
</tbody>
</table>

Table 4 shows two patients associated with Block B1. The condition for one patient is related with polyneuritis, while the condition for the other patient is related with septicemia, which is more complex. This may be the reason why this block exhibits high variance in time duration, even for the same chart access reason.

Block B2 belongs to UIB, and its reason R2 has long duration and large variance. As can be seen, the patients associated with this block are related to obstetric care. Furthermore, advanced practice nurses function as care providers, which includes the ability to create and sign chart orders, lessening the need for rapid access by a supervising attending.

Topic Workflow Types

To characterize the categories of workflows at the topic-level, we inferred 25 topics through distribution of blocks on patients, and then categorize the 25 topics of blocks into four groups using thresholds of a duration of 20 hours and a variance of 20 hours, as shown in Figure 5. Each topic is composed of top 10 blocks with highest probabilities. The duration and variance of a topic were calculated based on average durations of top 10 blocks. Topics 1, 7, 19, 20 were classified as Unstable Inefficient Topics (UITs), topic 8 was a Stable Inefficient Topic (SIT), topic 4 and 11 were Unstable Efficient Topics (UETs) and the remaining 18 topics were Stable Efficient Topics (SETs).

In Figure 5, it can be seen that topic 20 exhibits the longest time duration and corresponding variance. This is because one of the top 10 blocks of topic 20 belongs to UIB. This block corresponds to [NMH Physician Office – CPOE → SN-RN/Customer Service → NMH Physician Office – CPOE → SN-RN/Customer Service], which has 8 different reasons. The duration and variance of this block is 300 and 170 hours, respectively.

Figure 5. Average duration and variance of each of the 25 topics.

Case Study of a Complex Patient

The long duration and variance of topics may be due to the complexity of patients. To illustrate we conducted a case study of a patient who is characterized by seven topics.

Figure 6 shows the distribution of the number of topics needed to characterize a patient. It can be seen that most of the patients are characterized by 1 or 2 topics. We say patients who are associated with multiple topics are complex patients. Different topics characterize different types of patients. If a patient is associated with multiple types of topics, his condition should be quite complex.

To illustrate, let us consider one patient who was characterized by 5 topics and is associated with the conditions of multiple myeloma, diabetes mellitus, esophageal reflux, urinary tract infection, and personal history of malignant neoplasm of breast. This patient is associated with multiple blocks coming from different topics, of which we show two examples in Table 5. The first block is B3: [Rehab Speech → Rehab Speech] which has a long duration and large variance, while the other is B4: [Medical Records – Scanner → NMH Physician-CPOE], which has a short duration and variance.

Block B3 is associated with 3 reasons, and block B4 is associated with 5 reasons as shown in Table 5. The difference between reason R2 and R3 of the block B3 is Med Rec Release of Info and Med Rec Quality. The reason R3 associated with Med Rec Quality requires more time. If the reason following Med Rec Quality is Attending Phys/Prov (R1) instead of Patient Care (R3), then the time duration will increase. For block B4, the associated five reasons require a shorter duration, which suggests the block is stable and efficient.
system can enable an HCO to investigate and refine inefficient and unstable workflows.

We note that this is a pilot study on workflow extraction and modeling, but that the findings are promising as a roadmap towards the future. Specially, we believe that this type of investigation can be enhanced through several lines of research.

First, the reasons behind inefficient workflows clearly need to be studied in a more refined manner. Our work characterizes inefficiencies as a function of complexity in the patients and the surrounding workflows. For instance, one of our examples illustrates that residents assisting attending physicians (via access charts) may be a possible cause of inefficient workflows. Yet this explanation is limited in its explanatory power. Alternatively, or perhaps additionally, the reasons for inefficient workflows may include varying clinical urgency, variation in resource availability, varied clinical and system experiences of users, or even the design of EHR system itself. Further investigation of these factors will likely yield additional workflow representation optimization opportunities.

Second, the learned 25 topics need to be confirmed by clinicians. To do so, we will need to provide more nuanced contextual information about the patients associated with these workflows. Currently, the context of these patients is limited to the ICD-9 codes billed to insurance companies, which certainly does not cover the detailed conditions of a patient.

Third, the workflows our technique inferred are not associated with specific diseases. This will make it difficult for HCOs to determine where to invest in workflow optimization. We plan to construct the association study between workflows and diseases through data mining and machine learning technologies as a next step.

**Conclusion**

Modeling workflows for healthcare is challenging due to the complexity of clinical processes. In this work, we introduced a framework to model workflows at multiple levels of granularity. We illustrated that this framework can enable the categorization of workflows into four classes based on their duration: i) stable efficient, ii) unstable efficient, iii) stable inefficient and iv) unstable inefficient. We performed an extensive evaluation on Northwestern EHR event logs in the inpatient setting, where the results showed almost 95% of blocks are stable as well as efficient, and that over 80% patients are associated with efficient workflows. We further provided several illustrations of the reasons for inefficiency in a workflow and posited the main reason may derive from complexity of patients and the fact that Northwestern is a teaching hospital where residents are trained. Nonetheless, the reasons for inefficiency of workflows are diverse and will require additional contextual information (e.g., nuanced clinical data on patients, resource allocations of HCOs, and experiences of care providers) to further investigate and optimize workflows accordingly.

**Discussion**

Clinical workflow modeling can be a challenging endeavor because of the complexity of patients, variability in the healthcare environment, and changeover in staff. Poor documentation of workflow can limit the adoption, or successful implementation, of EHR systems. Our work provides a framework to generate such workflows at multiple levels of granularity via data mining. Our evaluation of the duration of such workflows enables the clear partitioning of existing workflows into four types, depending on their length and variability. We believe that such a characterization of the

Abstract

In recent years, Decision Support Systems (DSSs) have been developed and used to achieve “meaningful use”. One approach to developing DSSs is to translate clinical guidelines into a computer-interpretable format. However, there is no specific guideline modeling approach to translate nursing guidelines to computer-interpretable guidelines. This results in limited use of DSSs in nursing. Unified modeling language (UML) is a software writing language known to accurately represent the end-users’ perspective, due to its expressive characteristics. Furthermore, standard terminology enabled DSSs have been shown to smoothly integrate into existing health information systems. In order to facilitate development of nursing DSSs, the UML was used to represent a guideline for medication management for older adults encode with the International Classification for Nursing Practice (ICNP®). The UML was found to be a useful and sufficient tool to model a nursing guideline for a DSS.

Introduction

Clinical practice guidelines are indispensable to healthcare providers. Guidelines provide care recommendations which are synthesized from a systematic review of evidence to optimize patient care. Clinical practice guidelines are a vehicle to translate health care knowledge and outcomes of research into a user-friendly format. Many guidelines have been published by professional organizations, government agencies and health care institutions since they have been shown to reduce variation in practice and to improve the quality of care. Studies indicate that clinicians’ guideline compliance is increased when guidelines are implemented in a computerized decision support system (DSS) because they are able to deliver patient-specific care at the point of care\(^1,2\).

In recent years, meaningful use of health information technology has the expectation of improvement in the quality, safety, and even the cost of health care. Specific objectives to achieve meaningful use are developed by the Center for Medicare and Medicaid Services (CMS); one of the objectives involves using DSSs. CMS provides financial incentives to institutions that meet meaningful use requirements. To be eligible for incentive payments, one DSS should be incorporated into an institution’s electronic health record to support clinicians’ decision-making process\(^3\).

In spite of such important benefits, limited DSSs are used in nursing. One plausible reason is that DSSs developed for nurses often did not meet nurses’ information needs\(^4,5\). When a DSS is developed without accurate knowledge translated from a guideline, it does not provide accurate information to clinicians at the point of care. Studies show that formalization of guidelines as computer-interpretable guidelines (CIGs) makes a DSS more accurate and reliable\(^6,7\). Since most nursing guidelines are written in free text, tables and flow charts, it is necessary to develop CIGs to represent the underlying knowledge with explicit notations to define the semantics and provide reasoning mechanisms\(^8\). CIGs could facilitate development of various DSSs for nurses’ use, however, no formal modeling language to translate guidelines to CIGs has been developed for nursing use.

Unified Modeling Language (UML) is a software writing tool that has been widely used to model health information systems because of its useful effects of visualizing, specifying, constructing, and documenting the artifacts of a system from the end-users’ perspective\(^9\). It may also be a useful tool to model a nursing guideline from the nurses’ point of view.

DSSs also need to be integrated with existing health information systems for data reuse and patient-specific recommendations. Studies indicate that standard terminology enabled DSS can be seamlessly integrated with existing health information systems\(^10,11\). The purpose of this study is to illustrate steps involved in modeling a nursing guideline using the International Classification for Nursing Practice (ICNP®) and UML to develop a web-based medication management decision support system for older adults (Web-based medication management DSS).
Background

Computer-interpretable guidelines (CIGs)

A CIG is a systematically visualized and specified guideline by graphic notations to describe core knowledge of a guideline. This translation of a guideline has been useful to develop DSSs because it allows accurate and complete interpretation of guideline content. Studies show that CIG-based DSSs are easy to maintain (i.e. upgrading) and are adapted easily in local health care settings. Accordingly, many modeling approaches have been developed to represent and execute guidelines. Three distinct modeling approaches are found in the medical informatics community and categorized as: 1) Document models (i.e. Guideline Elements Model: GEM), 2) Decision tree and probabilistic models (i.e. Fuzzy Cognitive Maps: FCM) and 3) Task-network models (i.e. Guideline Interchange Format: GLIF). Despite such efforts, only a few guideline modeling approaches have progressed beyond the prototype stage.

Unified Modeling Language (UML)

The UML is a standard software writing language that was used to design and develop software systems. It is also an expressive language that can describe all the viewpoints needed to develop systems. It is used to: 1) visualize, 2) specify, 3) construct, and 4) document the elements of a software system. UML facilitates communication between developers and end-users of software by allowing them to examine objects in a system. Its ability to specify allows the UML to build a precise, unambiguous and complete system. A model constructed by the UML can also be mapped directly to an object-oriented programming language (i.e. Java or C++). Thus, a system prototype can be tested in early stages of the development, allowing for early refinement. In addition, UML can be used to document whole processes of developmental stages and tasks. These records help control, measure, and maintain a system after its deployment.

Standardized terminology in decision support systems

Due to the government emphasis on “meaningful use” for Electronic Health Records, DSSs are widely introduced in healthcare institutions. However, their adoption by clinicians has been slow and many challenges have emerged in development and implementation stages. One of the challenges is incorporating standardized terminology in a DSS. According to Ahmadian and colleagues’ literature review and survey, 58% of DSS developers experienced problems at developmental stages and 92% of these problems were related to data standardization. In addition to this, terminology standardization is an important requirement for scalable DSSs. Standard terminology and information models to represent health care data should be incorporated in DSSs for seamless integration.

To increase adoption and interoperability potential, a standard nursing terminology, ICNP was selected because it is a compositional terminology that facilitates the development of and the cross-mapping among local terms and existing terminologies. ICNP includes nursing diagnoses, nursing interventions and nursing-sensitive patient outcomes that describe nursing practice. The use of a standard nursing terminology such as ICNP facilitates description of nursing diagnoses, interventions, and outcomes for medication management nursing care and extraction of these data for later use.

Older adults and medication management

For older adults, the desire to remain independent as long as possible is critical. Research suggests that the ability to remain independent is highly dependent on the ability to manage medications. Multiple health conditions in the aging population often result in complex medication regimens that make this population vulnerable to adverse reactions to medications. The need for an electronic evidence-based decision support system to assist nurses in managing medications for older adults living the community is imperative. This type of computer system also has the potential to improve patients’ self-management of their health.

In recent years, health information technology has been used to improve care for older adults. Automated assessment tools and DSSs were developed and embedded in electronic health records. Nursing studies regarding teleHealth interventions were conducted. It is the appropriate time to develop a nursing DSS for older adults living in the community.
Modeling Steps

Step 1: Selection of a guideline for medication management for older adults

In the United State, approximately three million older adults are admitted to nursing homes because of their inability of manage a complicated medication regimen. It is estimated that the annual care cost for this population is $177 billion dollars17,21. Approximately 30% of hospitalizations of older adults are drug related and older adults who are discharged from the hospital with more than five medications are more likely to visit the emergency department and to be re-hospitalized within six months22. Unfortunately, due to complications with medications, older adults may not be able to live independently in the community. Nurses, aided by evidence-based decision support can partner with older adults and families in the community to safely manage medication.

A nursing practice guideline, “Medication Management of the Community-Dwelling Older Adult” (MM-guideline) was selected as a content source for this study. This evidence-based guideline was developed through support from the US Agency for Healthcare Research and Quality23.

Step 2: Extraction of concepts related to nursing processes in a selected guideline

After reviewing the MM-guideline, concepts related to medication management nursing processes and associated elements of each process were extracted. Processes and their associated elements were tabulated in a table. For example, “Risk assessment” was identified as a nursing process with ten associated elements. A total of eight processes were extracted and validated by a nurse expert. Table 1 shows four examples of extracted nursing processes and their associated elements.

Table 1. Four examples of nursing processes and associated elements extracted from a guideline

<table>
<thead>
<tr>
<th>Processes</th>
<th>Associated elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Risk assessment</td>
<td>name, age, living condition, chronic diseases, psychiatric diagnoses, number of medication, medication dosing schedule, complex medication, number of prescribing providers, changes in medication regimen within 1 month</td>
</tr>
<tr>
<td>Medication reconciliation</td>
<td>medication list, associated diagnosis, prescriber, dose, frequency, Beers criteria, adverse drug reaction, potential drug-drug reactions</td>

<tr>
<td>Medication procurement</td>
<td>difficulty obtaining or refilling prescriptions, viewing medications as too costly, funds to pay for medications or other financial burden, pharmacy delivery and/or refill reminder</td>
</tr>
<tr>
<td>Care plan</td>
<td>problems, interventions, expected outcomes</td>
</tr>
</tbody>
</table>

Step 3: Constructing an activity diagram

UML activity diagrams are typically used for computational and organizational processes modeling, for modeling the logic captured by use cases or scenarios, or for modeling the detailed logic of a processing rule. The activity diagram focuses on the action sequence of execution and the conditions that trigger or guard those actions. Activity diagrams are used for object-oriented software development while flow charts and data flow diagrams are used for structured software development24.

In order to create an activity diagram, actions and decisions are needed. All nursing processes in step 2 were identified as essential and necessary actions to manage medication for older adults. Then, any decision or parallel decisions which needed to be made were identified. Starting from an initial state symbol, actions were laid out in an order, and the flow from one action to another was represented using an arrow. The diagram ended with a final state symbol (Figure 1). Upon completion, a nurse expert, who specialized in community nursing with more than 10 years of research experience, validated the logical consistency of the activity diagram. Necessary revisions were made based on the nurse expert’s feedback. For instance, an assessment of each area of risk such as “Medication reconciliation” and “Medication procurement” was skipped algorithmically when there was no nursing problem identified in the first activity diagram. The nurse expert recommended that a nurse needed to assess all areas of risk
even if there were no problems identified in the initial risk assessment. In the second activity diagram, this suggestion was incorporated.

**Step 4: Construction of algorithms and mapping with ICNP**

Algorithms are well-defined procedures and an essential part of any computer system\(^\text{25}\). They can be written in pseudocode in early software developmental stages to test logics. Pseudocode is simple English like language that allows basic entity relationships to be expressed in a concise format. It can be parsed to build software modules and be rendered to computer languages (i.e. Java, C++, or Ruby programming language, etc.).

After algorithms were constructed based on nursing processes and logics from step 2 and 3, pseudocodes for each nursing process were written. Figure 2 shows examples of pseudocodes written for a web-based medication management DSS. Total seven care plans were extracted from the MM-guideline and data items of problem, intervention and expected outcomes of all seven care plans were mapped with ICNP.

![Diagram](image)

**Figure 1.** An activity diagram constructed for a web-based medication management DSS

**Step 5: Identifying software requirement specification**

A software requirements specification is a comprehensive description of software under development. It describes what the software will do, how it will interact with end users, what the boundary of the software is and how it will be expected to perform. Purpose of this description is to minimizes the time, effort and cost required by developers to achieve desired goals for software users. In this study, guidelines from IEEE\(^\text{26}\) were used to describe the web-based medication management DSS.
For example, eight required functionalities were identified and written as:

1. Web-based medication management DSS shall display data entry screens for user.
2. Web-based medication management DSS shall allow user to select a patient.
3. Web-based medication management DSS shall allow user to enter new patient.
4. Web-based medication management DSS shall display screens with data entry tools such as checkboxes, dropdown menu, or text-field.
5. Web-based medication management DSS shall allow user to move screens forward and backward.
6. Web-based medication management DSS shall display nursing intervention list.
7. Web-based medication management DSS shall allow user select interventions from the list.
8. Web-based medication management DSS shall allow user to save identified risk factors and provided nursing interventions into database.

**Figure 2.** Examples of algorithms constructed for a web-based medication management DSS

---

Step 6: A web-based medication management DSS

A web-based medication management DSS was programmed based on information from steps 1 to 5. Only two instances of clarification between team members and a programmer were needed. Once a prototype was programmed, team members performed alpha testing for a web-based medication management DSS. Three functions of a web-based system were not working correctly and were adjusted during alpha testing. Figure 3 shows the initial (middle), risk assessment (left lower) and Medication reconciliation assessment (right lower) screens of a developed system.
Discussion

Unified Modeling Language (UML) was developed to compose software and to assist the developer to model a computer system. Its descriptive nature describes a potential computer system accurately before implementation. For this reason, the UML was selected as the tool for modeling a guideline in this study. During the modeling processes, the UML was found to be a useful and sufficient tool to describe the Medication Management of the Community-Dwelling Older Adult guideline for a web-based system. It may be recommended that nurse informaticians utilize the UML when they model a nursing guideline for a decision support system for nurses’ use.

The UML has been used for modeling in many studies, but only one study has been reported in the nursing domain. Therefore, representing this nursing guideline with the UML is a significant first step in preparing nursing guidelines for implementation as decision support systems. Since there are limited computer systems for nurses’ use to date, the approach described may be useful in two ways: 1) it may facilitate interactions between a nursing informatician (on behalf of nurse users) and a developer to implement a computer system that nurses prefer; and 2) it may enable the maintenance of a model of a computer system that is easily modified for upgrades.

Limitations

The study findings have limited generalizability because the 1) UML modeling process was tested with only one guideline, 2) accuracy and completeness of translation of UML should be compared with those of other guideline modeling approaches (i.e. GLIF) and 3) the web-based medication management system was not tested with real patients’ data. Future research is necessary to develop decision support systems by following steps in this study with different guidelines and to test this system in community or public health nursing practice.

Abstract

Characterizing a rare disease diagnosis for a given patient is often made through expert’s networks. It is a complex task that could evolve over time depending on the natural history of the disease and the evolution of the scientific knowledge. Most rare diseases have genetic causes and recent improvements of sequencing techniques contribute to the discovery of many new diseases every year. Diagnosis coding in the rare disease field requires data from multiple knowledge bases to be aggregated in order to offer the clinician a global information space from possible diagnosis to clinical signs (phenotypes) and known genetic mutations (genotype). Nowadays, the major barrier to the coding activity is the lack of consolidation of such information scattered in different thesaurus such as Orphanet, OMIM or HPO. The Linking Open data for Rare Diseases (LORD) web portal we developed stands as the first attempt to fill this gap by offering an integrated view of 8,400 rare diseases linked to more than 14,500 signs and 3,270 genes. The application provides a browsing feature to navigate through the relationships between diseases, signs and genes, and some Application Programming Interfaces to help its integration in health information systems in routine.

Introduction

Eighty percent of Rare Diseases (RD) have a genetic origin. Presently, 3,000 among more than 7,000 rare diseases have an identified gene.1 Moreover, clinical signs are often used to characterize RD.2 Even when a consensual disease classification is used in a registry for RD centers,3 the “not confirmed” category represents 1 out of 4 cases (17% undetermined, 9% could not be classified yet). The identification of patients with rare diseases at international level is a key requirement to accelerate patient recruitment for clinical trials and cohorts. This work is proposed within the framework of the second French National Plan for Rare Diseases (2011-2016) where the French National Database for Rare Diseases infrastructure (BNDMR)3 is defined. The BNDMR is a priority project of the National Plan and aims at gathering a common minimal data set for all rare diseases patients at nationwide scale5 to facilitate patient recruitment in clinical trials and in cohorts as well as public health studies. A common terminology is required to register patient diagnosis and enable statistical use of the data. The French Ministry of Health encourages the use of Orphanet6 for national coding of RD while the European Commission recently decided to recommend Orphanet as an European terminology for RD diagnosis coding.7

In order to properly code rare disease patients into health information systems (medical records, registries or cohorts), several issues have been discussed by health information specialists and clinicians: (i) poor information on rare disease is available in standard morbidity classifications (ICD-9 to ICD-10); the ICD classification is often used for reimbursement purposes in pay-for-performance systems, and is not well adapted to describe patient’s clinical status, (ii) to code a patient diagnosis, there is a possible need to gather information from other knowledge bases, such as genetic and phenotype information, (iii) navigating within more than 7,000 RD cannot be done through a tree navigation or a list navigation. Search algorithms are nice but context dependent navigation is a key feature (a context can be a medical field), (iv) RD are often multi-systemic, thus mono-parental classifications such as ICD might not be adapted.

Coding systems (thesaurus, classifications, terminologies, controlled vocabularies) are used to enable controlled data entry in health information systems in order to facilitate data analysis for quality of care,8 epidemiology9 or research.10 Historically, the International Classification of Diseases (ICD) was used to measure mortality in
populations. Its usage was progressively redefined to measure morbidity and was then integrated within global hospital information systems with some difficulties. In the rare disease field this classification does not provide us with the necessary RD completeness (only 300 rare diseases are described) and when described, rare diseases are not necessarily used as the primary or secondary diagnosis since the visit of the patient might be related to a comorbidity (e.g. respiratory distress for a Cystic fibrosis patient). There are few resources available that can help in classifying RD patients: Orphanet, OMIM, HPO, the GARD disease nomenclature (https://rarediseases.info.nih.gov/gard) or SNOMED CT. These resources do not present the same information type or completeness but they could be used together to specify patient rare conditions with a relatively good phenotypic or genotypic precision.

In this paper, we will not discuss the adequacy of using Orphanet as a coding system to record morbidity in the rare diseases field nor the curation made by Orphanet, OMIM and HPO to interlink their resources. We will focus on implementing a tool that could use the Orphanet proposed views (multi-parental and multi-classified diseases) to help guiding professionals to the right disease (medical coding assistance). Besides, we will propose to enrich each of the Orphanet disease with genetic and phenotypic information available from OMIM and HPO to provide a richer presentation of the disease. Many terminology sources are available, and it is now crucial to be able to bring data from different sources together into one application to help clinicians in their coding task. Available web applications do provide parts of the information for a given disease (http://www.orpha.net, http://omim.org). Few projects offer to link the diseases all together (Diseasecard, HeTOP, or Orpha.net) but they do not provide the actual information from all sources into the same web interface. We propose in this paper a new generation application for rare diseases coding assistance based on semantic web/RDF technologies for the rich semantic linked data DB on one hand and NoSQL/JSON for the web services technologies access on the other hand.

Methods

The semantic integration of biomedical knowledge sources and datasets is a complex data engineering issue. In order to enable the integration of different datasets, our architecture is based on a first semantic integration layer that deals with the heterogeneity of source formats as well as the semantic heterogeneity of proposed representations of diseases. We then defined a presentation layer composed of a NoSQL database well fit to represent JSON complex biomedical objects to be displayed through a Ruby on Rails web application. That architecture combines the use of semantic web technologies that have great expressivity capabilities (RDF, OWL) but have a footprint on performance for real-time applications, with the flexibility and performance of NoSQL technologies to provide the best user experience when navigating through complex biomedical data.

---

**Figure 1.** Genetic-phenotypic semantic database integration architecture for rare diseases. The first layer function deals with the technical and the semantic integration of various data sources. The second layer deals with presenting the data and navigating through views.

1. **Integration layer**

The integration of various externally curated multi-lingual biomedical datasets requires expressive models and semantic robustness to express exact, broader-than and narrower-than alignments as well as reasoning. We have
chosen to integrate the datasets into a RDF triple store (Openlink Virtuoso®) through a homemade integration layer (xml and java data integrators). Each data integrator was developed specifically for each data source as data structures and format of sources were heterogeneous. Orphanet data is released using xml based on a local model extraction without xsd, OMIM is available as a set of flat text files and HPO as an OBO or OWL file. Whilst the HPO file has a rich semantic web compatible serialization format, Orphanet and OMIM are not semantic web compatible, semantic links between concepts were thus rebuilt to be compliant with RDF. Table 1 reflects the volume of integrated triples in the RDF triple store.

Overlaps between these three datasets to represent disorders (diseases) were enumerated in the disease ontology. The Orphanet source also offers cross referencing to HPO and OMIM and other datasets. They also produce more than 30 views (named diseases classifications by Orphanet) organized per rare disease groups (including 1 non-rare diseases group). Each disease group is organized into several entities such as categories of diseases, diseases, clinical subtypes, etiological subtypes, etc. These views are curated by Orphanet and will be used to implement the navigation functions of the LORD application. Rare diseases are numerous and can often have several medical expressions. For instance, patients diagnosed with Fabry disease [17] can present several anomalies: renal, cardiac, neurologic, dermatologic, ophthalmic etc. The classification can also be used to make differential diagnosis, if the patient present a Cataract associated with a metabolic disease [18], then the patient could be suffering from Fabry disease, but also Refsum disease, De Bary syndrome, Galactosemia or Alpha-mannosidosis diseases (given by Orphanet views). Searching from clinical signs is not supported in this version of the LORD application.

2. Presentation layer

Semantically enriched biomedical data stored in native RDF triplestore generally suffers from a performance footprint when queried on a large scale application with real-time navigation features on the web. On the other hand, new generation web applications (Ruby on Rails, Backbone.js) can be easily built up using a full web service architecture managing JSON objects. JSON objects are similar to rich XML objects and can be stored in NoSQL databases such as MongoDB, allowing flexibility for model changes as well as best in class performance and scalability using sharding techniques if needed (data atomization over MongoDB servers and query balancing).

To generate JSON objects, SPARQL queries are processed on the RDF triplestore, and resulted JSON objects are stored into the NoSQL database in batch mode, every day. Such a process can be applied from the same RDF triplestore to numerous presentation databases for various projects if needed. Once integrated and formatted for presentation as JSON objects, the NoSQL database is indexed and searched through an Elasticsearch engine (http://www.elasticsearch.org) enabling auto-completion, multi-field, ranked searches as well as various possible optimizations. The search engine enables search over disorder names and synonyms, Orphanet numbers and genes. Given the nature of the Orphanet resource (multi-view and multi-parental), we pre-calculated all possible concept parents and sons to help with the navigation feature of the interactive graphical interface. Hence, when a user selects a disorder, he can view direct neighbors of the given disease.
The result is returned and displayed to the user in a graphical and textual interface. We defined a navigational area and a content area. Users can navigate through classifications, filter classifications and diseases, and add current disease to a disease ‘basket’ for exportation if the application is integrated with an EHR or a patient registration system. They have then access to all information available from Orphanet, HPO and OMIM for the selected disease on the same screen. The Human Rare Disease core Ontology (HRDO) provides a meta-model for this presentation layer implementation.

Figure 2. The disease interface of the LORD application. The filtering view gives access to filters based on medical specialities. The graphical tree navigation enables navigation through diseases, symptoms and group of diseases. The external thesaurus links allow the user to be redirected to source sites pages of diagnosis. The disease content view represents disease definition data from Orphanet, signs from HPO and clinical synopsis and genetic data from OMIM.

Results

One of the objectives of the project was to be able to create a common, curated and semantically rich knowledge repository to help managing the complexity and heterogeneity of biomedical databases. Data are openly available but with poor usability, as they are not integrated into a single application. Update frequencies are heterogeneous and as the sources are interlinking their datasets, they present some data in common. It is therefore necessary to build an integrated semantic database that can also serve as a national terminology server for several purposes: search terms, search based on clinical signs, disease complete data retrieval, integration within another application of the curated database. The RDF datastore can be queried over the semantic web SPARQL query language which is the most advanced query language enabling reasoning, inference and federation. It is compatible with Linked Data principles. Data can also be queried directly through a secured web service directly on the NoSQL database, depending on the use case of the user.
When connecting to the application (http://enlord.bndmr.fr) the user can browse the data through 2 modes. Either using the search function, or by browsing using proposed Orphanet views. An Elasticsearch engine that provides multi-criteria searches over several data sources powers the search function. Users can search through diseases preferred label, alternative label, gene or Orphanet number. The search engine enables word search regardless of the position of the word within the disease label. Given the length of some disease names, this feature is important. For instance, the *Anhidrotic ectodermal dysplasia - immunodeficiency - osteopetrosis – lymphedema* Orphanet disease (http://enlord.bndmr.fr/#disorders/69088) which is composed as a set of symptoms. By navigating backwards in the hierarchy to *Osteopetrosis* (http://enlord.bndmr.fr/#disorders/2781) the user can search over a limited set of diseases that share Osteopetrosis, if it is the observed symptom.

When users are navigating through diseases graphs, they can filter the displayed concepts. For example, while looking at *Cystinosis* information (http://enlord.bndmr.fr/#disorders/213/97966), the user can filter on Rare eye diseases (if he is an Ophthalmologist) and then navigate through symptoms that are related to his medical expertise: *Unclassified maculopathy, metabolic disease with corneal opacity or metabolic disease with pigmentary retinisis*. We should emphasis that the nature of the disease “groups” here differs from the previous example. While the first “groups” are related to symptoms of a disease, the seconds are diseases classifiers.

The user then can have access to textual information from OMIM and HPO for a given disease and epidemiological information from Orphanet. As relations between data sources can be one to many (1 Orphanet disease for n OMIM entries) then we have developed an OMIM entry selector to help user navigation and data retrieval. From the web service standpoint, all data of all OMIM entries are gathered in the same JSON object for an individual Orphanet disease.

**Discussion**

We defined and built a new generation web application to help clinicians and health information specialists to navigate in the Orphanet rare diseases for diagnosis coding. We first integrated and curated various terminologies and classifications (Orphanet, HPO, OMIM, HRDO) related to our domain within a semantic database adapted to reasoning and compatible with linked data principles. Once curated and qualified, the semantic biomedical data is transformed into JSON complex objects and stored in a NoSQL database for presentation and navigation through a new generation web portal. This 2-layer application architecture has proven to combine both generally distinct paradigms: expressivity and performance.

The biomedical data we integrated can be used in other applications, either using directly SPARQL (SPARQL endpoint not publicly available yet), or through web services. For instance, through the search engine, the “cystin” search query could be executed following a command line or web request (GET) http://enlord.bndmr.fr/disorders/search/cystin.json?[page=N]. The result will be a JSON object:

{"term":"cystin","page":1,"total":1,"lastPage":1,"results":[Full collection of diseases found]} that can be directly processed within a third party application. The access to the data through APIs and the application browser are freely available in French and English.

The application was evaluated by clinicians and information managers and used in real setting. The quantity of information on screen was judged good as well as the navigation functions. Clinical geneticists requested more OMIM data and clinicians less Orphanet concepts and more precision upon signs. Some indicated that not all information is useful to all professionals. Medical experts also argued that Orphanet classifications cannot be seen as a diagnosis assistance tool (guiding the clinician from presentations of the disease to the precise disease). Others considered that Orphanet as a master terminology might not be sufficient, as rare manifestations do not have necessary a known diagnosis and diagnosis certainty is a key requirement in the rare disease field. Geneticists also criticized data update latency of OMIM and Orphanet as new genes or mutations are found regularly. Last and most important, not all patients can be given a diagnosis at a certain point of time. The disease might naturally evolve (in case of a genetic disease) over time or the patient might or might not express it. Hence the application should update the thesaurus rapidly but, even with fast updates, the application solely relies on pre-curated terminologies by external parties. The presence of a correct entity to represent at the right granularity (clinical sub-type, disease, group of diseases, disease category) is, for the moment, entirely relying on our data providers. Granularity is also seen by health professionals as a barrier to a homogeneous national data collection for later statistical exploitation of data. A better updating process of these databases by users should be set in order to help Orphanet/HPO/OMIM in their curation tasks which are time consuming. Finally, for the coding task, instructions for coding RD should be elaborated in collaboration with RD expert networks. We foresee in the next months a formal evaluation of
the application whilst the new generation application for data collection for RD centres is rolled out in France (BaMaRa). During the rollout, data accuracy and quality, as well as navigation within the LORD application will be evaluated. Also, coding cases will be set to assess the views proposed by Orphanet as well as the navigational behaviours of the application for that particular purpose.

The application is not yet used in routine in France in all hospital information systems as the coding of rare diseases has not yet started in hospital information systems. As at today, the application is used by 200 users monthly. Users are located in France, Spain, Belgium, Switzerland, Germany and the United States. It is also used by some French university hospitals in clinical routine and by Orphanet France and Switzerland for navigating through their data and for curation.

This first version of the application could be enhanced in many ways. First, we could integrate other existing initiatives like DiseaseCard, which offers more links to external sources than Orphanet. Second, we could help the coding specialist or the expert physician to code the diagnosis from the patient discharge letters. Third, we could develop a search by sign engine that could provide a list of candidate diseases. Fourth, we could propose on the same infrastructure a signs navigation engine for HPO. Fifth, we could enrich the coding possibilities to other nomenclatures such as HPO, OMIM, CIM10, SNOMED since not all rare diseases are represented in Orphanet only. The application is also seen as a potential coding application for the RD-ACTION European joint action (2015-2018) that could also serve as a European terminology service integrated hub for coding rare diseases across European countries.

Conclusion

We introduced a new generation application to lighten the burden of rare diseases codification of cases based on controlled vocabularies. LORD results are significant as (1) the proposed architecture is set on the latest standards (Semantic Web, RDF, JSON, NoSQL, REST) and is flexible enough to curate complex biomedical objects and navigate through them easily at large scale, (2) it brings to users many information about a rare disease into the same UI (genotypic, phenotypic, epidemiological) (3) it could help in some rare cases, in defining the right disease by disease similarity analysis for differential diagnosis, (4) it can help in being more precise in the classification of a disease, (5) it facilitates the specialist navigation through complex graphs of concepts by applying filters on the data (rare eye diseases, rare kidney diseases, etc.).

Acknowledgements

The French Ministry of Health funded this work under the second national plan for rare diseases. We thank our data sources (Orphanet, OMIM, HPO) for their great work in curating and interlinking constantly their respective databases. We warmly thank Céline Angin for her editing and design work.

Characterization of the Context of Drug Concepts in Research Protocols: An Empiric Study to Guide Ontology Development

James J. Cimino, MD¹,² and Vojtech Huser, MD, PhD²

¹Informatics Institute, University of Alabama at Birmingham, Birmingham, Alabama
²Lister Hill National Center for Biomedical Communications, National Library of Medicine, Bethesda, Maryland

Abstract

We examined a large body of research study documents (protocols) to identify mentions of drug concepts and established base concepts and roles needed to characterize the semantics of these instances. We found these concepts in three general situations: background knowledge about the drug, study procedures involving the drug, and other roles of the drug in the study. We identified 18 more specific contexts (e.g., adverse event information, administration and dosing of the drug, and interactions between the study drug and other drugs). The ontology was validated against a test set of protocol documents from NIH and ClinicalTrial.gov. The goal is to support the automated extraction of drug information from protocol documents to support functions such as study retrieval, determination of subject eligibility, generation of order sets, and creation of logic for decision support alerts and reminders. Further work is needed to formally extend existing ontologies of clinical research.

Introduction

Clinical research studies involve complex work flow that might benefit greatly from automated processes to assist with tasks such as retrieval of study information, subject recruitment, data collection procedures, administration of study interventions, resource planning, and decision support for clinicians caring for research subjects. Such processes will necessarily depend on representing study concepts and procedural knowledge through formal mechanisms such as ontologies and logic. To that end, Sim and colleagues¹ have worked to develop the Ontology of Clinical Research (OCRe) intended to represent a broad range of research study concepts. Efforts to define and use such concepts have been especially successful with respect to characterizing the eligibility criteria by which research subjects are selected for or excluded from studies.²

Research protocols still typically consist of lengthy, loosely structured text documents—a format that confounds the application of automated tools. However, Tu and colleagues³ demonstrated that formal representations of study concepts could be developed by identifying interesting text phrases in protocol documents and then representing their semantics using a template-based formalism called ERGO. Their findings support the notion that, when combined with natural language processing, automated extraction of research concepts (such as eligibility criteria) and their conversion to computable form is possible. Drugs are particularly interesting because of their involvement with many aspects of research. For example, over 35% of the subject eligibility phrases selected for the ERGO study, reported by Ross and colleagues,⁴ involved drug concepts (Sim I, personal communication).

In work at the National Institutes of Health (NIH),⁵ we examined the roles of drugs in research studies from a somewhat different perspective, namely documenting the drugs that were restricted from use in research subjects. Like the ERGO study, we found many instances in which subjects would be excluded from a study due to previous exposure to a particular drug or class of drugs. However, we also found many restrictions that related to use of drugs during the course of the study, sometimes in complex situations (e.g., “do not give any drugs that will prolong the patient’s QT interval within 5 half-lives of the administration of the study drug”).

As a result of our analysis of NIH research studies, we developed a medical logic module for use in electronic health records that would warn clinicians attempting to order a drug that is restricted in one of the studies in which the patient at hand was participating. As part of an effort to expand decision support around “drug-study interactions”, we explored the relationships involving drugs in all aspects of research study documents (protocols) with the goal of identifying the breadth of contexts in which drug concepts appear. This empirical work provides one approach to extending existing ontologies so that they, in turn can be used represent drug information to automate a variety of research-related tasks, such as study retrieval, subject eligibility determination, generation of research-specific order sets, and creation of logic for decision support alerts and reminders. This paper reports on the results of a formal analysis of study documents related to research at the NIH Clinical Center and in the National Center for...
Biotechnology Information’s ClinicalTrials.gov database, establishment of a base set of roles, and speculates on the potential advantages of being able to determine which drugs have which roles in a research study.

Methods

Because research documents may discuss drug concepts without mentioning specific drugs (for example, by mentioning classes of drugs or by simply saying “drugs”), we developed a set of search words for identifying direct and indirect references to drug concepts. The initial set was based on text search words we used in our previous study, combined with key words in the text phrases identified in the ERGO study.

We obtained a convenience sample of protocol documents for active and terminated studies at the NIH Clinical Center, conducted by researchers at 13 different NIH institutes and centers. We set aside 10% of these documents for use as a test set and then searched the remaining documents (the development set) for ontology development. We first searched a subset of the development set to locate drug terms (e.g., specific named drugs and drug classes). We then examined occurrences of these particular drug terms in the development set to find additional words associated with the drug terms that might be useful in searching study documents.

We searched the development set, one study document at a time, for any occurrences of any of the search words (with stemming, such that “chemotherap” would find both “chemotherapy” and “chemotherapeutic”). One of us (JJC) reviewed each occurrence to determine if it involved information about a drug (for example, the search word “administer” might involve a drug or a survey or might simply refer to administration of the study itself).

Once a relevant phrase was identified, it was copied to a spreadsheet. This task was complicated by the fact that most of the documents were created using the Portable Document Format (PDF). While the optical character recognition function in Adobe Acrobat (Adobe Systems Incorporated, San Jose, CA) made scanned documents searchable, many typographical errors needed to be corrected manually. Subsequently encountered phrases that were identical or nearly identical were not included in the spreadsheet. The process was halted when ten consecutive protocols were searched without identifying any phrases that differed semantically from previous findings. Once the spreadsheet of phrases was assembled, ontology creation was accomplished by through manual inspection, classification and description, similar to methods used in other analyses of research study documents.

To the test set we added study descriptions (in XML format) obtained by searching ClinicalTrials.gov for the “top 100” studies that contained the term “2015”. This expanded test set was provided to one of us who had not seen the ontology (VH) with instructions to highlight 100 phrases that involved drugs in some way. The researcher was encouraged to ignore phrases that were similar to previously highlighted phrases to improve the variety, and thus the coverage, of the test phrases. Once the phrases were identified, they were coded independently by each of us using the ontology. Results were pooled and inter-rater discrepancies were reviewed and reconciled by both coders.

Results

Development of Source Material

The convenience sample included study documents from 866 active and terminated studies at the NIH Clinical Center, conducted by researchers at 13 different NIH institutes and centers. We set aside 87 (10%) of these documents for use as a test set and used the remaining 779 documents as the search set.

Our original set of three search words (“exclu”, “prohib”, and “concomitant”) was expanded with 54 words from the ERGO data. The search for 20 drug terms identified “5-FU”, “acetaminophen”, “Antibiotic”, “Antihistamine”, “antipyretic”, “aspirin”, “baclofen”, “Botulinum”, “cisplatin”, “Dexamethasone”, “doxorubicin”, “Filgastrim”, “ibuprofen”, “ISOVUE”, “Leucovorin”, “lithium”, “metoprolol”, “statin”, “vaccine”, and “vitamin”. We found these drug terms 893 times in 52 documents, which helped identify 12 additional search words (“intrathecal”, “continue”, “dosage”, “allowable”, “infusion”, “monotherapy”, “formulary”, “nonformulary”, “rescue”, “eluted”, “elution”, and “chemoembolization”). The final set of 69 search words is shown in Figure 1.

Searching the 779 protocol documents in the search set with the text words shown in Figure 1 yielded 481,077 results, the vast majority of which were false positives. We therefore started our review with the 103 documents from studies conducted by Clinical Center investigators and then continued the review with selected documents from recent studies conducted by investigators at each of the other 12 clinically active institutes before halting. Altogether, this review identified 72 examples of semantically distinct text samples.

* https://clinicaltrials.gov/ct2/resources/download
Ontology Creation

Semantic categorization began by noting that many drug-related phrases involved background information about the drug that was not specific to the study, for example, history of experience with the drug or pharmacologic information about the drug. We also noted that when drugs were discussed in relation to the study, they might be related to an actual procedure to be carried out in the study (for example, administration of the drug) or they might be related in some other way (for example, data collection about use of the drug). We initially classified each of the 72 text samples into one of three classes: Background Information, Study Procedure, and Relation of Drug to Study. Within the classes, we then further classified text samples as relating to specific background information (3), study procedures (7) or other relationships (8). The resulting three classes and 18 specific drug roles is shown in Table 1.

Ontology Evaluation

The extraction of text samples from the test set produced 102 samples. Initial coding by both coders working independently resulted in 11 discrepancies (89% agreement), although VH suggested possible alternatives in two cases that matched JJC's classification (91% partial or complete agreement). After further discussion of the 18 concepts, the coders agreed on 101 cases (99%). The 11 discrepancies and their resolution are shown in Table 2.
Table 2. Coding discrepancies from test set (codes in parenthesis are initial alternate suggestions by Coder 2).

Discussion

Contribution of the Study

This study identified three general and 18 specific roles that drugs may have in research studies. Not surprisingly, some of these roles are already represented in existing clinical research ontologies. In particular, ERGO covers the representation of drug use that are required for subject inclusion in a study or that result in subject exclusion from a study. However, additional relationships that involved drug administration or exclusion after subject enrollment.

While these ontologies can be expanded through theoretical mechanisms (for example, thought experiments about how drug terms might appear in study protocols), the empiric approach of studying actual protocols, taken by us and others,\(^3^,\(^4^)\) can at least serve as a reality check of an ontology’s completeness and may produce findings that might not have been anticipated through a purely theoretical approach. Our study contributes to this effort through review of a fairly substantial set of protocols.

Limitations

Despite the review of a large set of documents, a relatively small set of contexts was found. While reviewer fatigue may have been a contributing factor, the evaluation phase of our study found that an independently selected set of contextual statements was fully classifiable with the modest set discovered in the development phase of the study.

The development of the 18 roles was based on contextual phrases found in study protocols obtained exclusively from the NIH. The repetitive nature of the language found in the protocols, across 13 institutes and centers, dozens of specialties and hundreds (or perhaps thousands) of study authors suggests some possible cultural and habitual
effects. However, part of the test set (but not the training set) was drawn from protocols entered into the ClinicalTrials.gov database, which reflects a national pool of research. This suggests that the ontology thus developed is not NIH-specific.

Finally, this work does not directly provide an extension to any particular ontology and duplicates some previous work by others. Additional work is necessary to represent the knowledge gained in this study in a more formal manner. The ERGO framework\(^3\) appears to be a suitable path forward.

Potential Applications of Drug Context Information

Based on our own work at examining the ways in which drugs may adversely affect study procedures,\(^5\) it is clear that even the discovery of free-text phrases in relevant contexts can be useful, since they can serve as the basis for alerting messages to remind clinicians of study-specific requirements for patient management (e.g., “this drug should only be given to the subject to treat certain autoimmune disorders”). Deeper representation of such contexts (for example, allowing alert logic to handle exceptions to the alert) may be more elusive. However, even simple information can be actionable and given the richness of contexts of drugs in research studies, knowing when a drug that is mentioned in a protocol is *not* in a particular context may be valuable as well. It may therefore be useful to speculate on the kinds of capabilities that are possible by knowing more specific information about a drug’s context in a protocol. Table 3 provides some examples and the reader is encouraged to consider others.

Conclusion

We reviewed a large set of protocol documents in order to contribute to knowledge about the roles of drugs in research protocols. Our findings can serve as the basis for subsequent work on the development of clinical research ontologies for use in improving the quality of the research process through improved planning and execution of studies with, for example, study-relevant forms, orders sets and alerts.

Acknowledgments

This work was supported in part with intramural research funds from the NIH Clinical Center and the National Library of Medicine. The authors thanks Ida Sim, Samson Tu and Simona Carini for helpful information regarding OCRe and ERGO, in particular the sharing of the data set used for the ERGO study.

Improving EHR Capabilities to Facilitate Stage 3 Meaningful Use Care Coordination Criteria

Dori A. Cross, BSPH1, Genna R. Cohen, BS1, Paige Nong, BS1, Anya-Victoria Day, MPH2, Danielle Vibbert, MPH2, Ramya Naraharisetti, M.Sc.2, Julia Adler-Milstein, PhD1,3

1 School of Public Health, University of Michigan, Ann Arbor, MI; 2 Altarum Institute, Ann Arbor, MI; 3 School of Information, University of Michigan, Ann Arbor, MI

Abstract

Primary care practices have been limited in their ability to leverage electronic health records (EHRs) and health information exchange (HIE) to improve care coordination, but will soon be incentivized to do so under proposed Stage 3 meaningful use criteria. We use mixed methods to understand how primary care practices manage, share and reconcile electronic patient information across care settings, and identify innovations in EHR design to support enhanced care coordination. Opportunities identified by practices focused on availability and usability of features that facilitate (1) generation of customized summary of care records, (2) team-based care approaches, and (3) management of the increased volume of electronic information generated and exchanged during care transitions. More broadly, vendors and policymakers need to continue to work together to improve interoperability as the key to effective care coordination. If these EHR innovations were widespread, the value of meeting the proposed Stage 3 care coordination criteria would be substantially enhanced.

Introduction

Background: The centerpiece of the Health Information Technology for Economic and Clinical Health (HITECH) Act of 2009 is financial incentives for providers who implement electronic health records (EHRs) and use them in accordance with federally-specified meaningful use criteria.1 Criteria that promote care coordination are heavily emphasized because of the potential for EHRs, coupled with electronic health information exchange (HIE), to enable sharing of patients’ health information between delivery settings and ultimately improve the quality, safety, and efficiency of care. These criteria were, however, largely deferred to later stages of meaningful use because few providers had EHRs that were capable of exchanging or using electronically shared clinical data for effective care coordination.2,3,4

Objectives: We sought to identify EHR capabilities and innovations that would better enable primary care practices to meet the proposed Stage 3 care coordination criteria in a meaningful way.

Methods

Our study focused on the proposed Stage 3 meaningful use care coordination criteria from the perspective of primary care practices. At the time the study was designed, there were three proposed care coordination criteria:

1. SGRP 302: Reconcile patients’ medications for more than 50% of transitions of care and reconcile patients’ medication allergies and problems (e.g., uncontrolled diabetes) for more than 10% of transitions in care.

2. SGRP 303: Send a summary of care record (SCR) for at least 65% of transitions of care or referrals with at least 30% sent electronically. [SCRs for referrals must include a “concise narrative in support of care transitions,” i.e., free text that captures the current care synopsis and expectations for referral.]

3. SGRP 305: Be prepared to receive an EHR-generated acknowledgement from practices that received information from the focal practice for at least 50% of referrals, i.e., a referral receipt, with at least 10% returned electronically.

Design and Setting

We use mixed quantitative and qualitative methods to identify technical barriers faced by primary care practices in the state of Michigan that are pursuing proposed Stage 3 meaningful use care coordination criteria, and develop recommendations for EHR innovations that would best enable practices to meet the criteria in ways that improve care coordination. Our study included a statewide survey of 328 primary care practices, complemented by three
rounds of interviews in 12 representative primary care practices (the implementation sample) working towards proposed Stage 3 care coordination criteria. Sample descriptive characteristics are reported in Table 1. All practices in both samples had achieved Stage 1 Meaningful Use (as of September 1, 2013) with support of the Michigan Center for Effective IT Adoption (M-CEITA), the Michigan Regional Extension Center.

* In Michigan physician organizations are umbrella organizations—such as independent practice organizations, physician-hospital organizations, and large multispecialty group practices—that provide clinical leadership, administrative structure, technical infrastructure, and other resources for physician practices.

Data Collection

Survey: The statewide survey captured practice demographics, readiness for Stage 2 and Stage 3 meaningful use care coordination criteria, health information exchange (HIE) participation, facilitators and barriers to meeting Stage 3 criteria, perceived impact of Stage 3 criteria and optimal approach to information sharing to support care coordination. Some questions were targeted to the practice manager (PM) and others were targeted to a primary care provider (PCP) in the practice.

A random sample of 328 primary care practices completed the survey between November 2013 and March 2014. Participants were offered multiple means to complete the survey: phone, online (Qualtrics), or on paper via fax or mail. We received responses from 233 practice managers (71% response rate) and 174 primary care providers (53% response rate). Data were imported and analyzed in STATA 12.0. We estimated all figures using survey sampling weights based on our sampling strategy in order to generalize results to the statewide population of primary care practices that had achieved Stage 1 meaningful use.

Implementation Sample: We selected 12 practices to receive technical assistance to facilitate achievement of proposed Stage 3 meaningful use care coordination criteria. We conducted three rounds of semi-structured interviews with key practice staff (the practice manager and at least one PCP) between October 2013 and June 2014; interviews were in person at the outset of implementation (i.e., before attempting to achieve the Stage 3 criteria), by phone three months later, and again in person six months following initiation of implementation. The initial round of interviews focused on current state processes of supporting care coordination using EHRs. The second round of interviews focused on barriers to achieving Stage 3 care coordination measures and potential strategies to overcome them. The final round of interviews focused on progress towards achieving the criteria, suggested changes to the criteria, strategies for increasing the impact of the criteria, and EHR innovations to support criteria achievement. Interview guides were developed using the Consolidated Framework for Implementation Research, which provides a pragmatic structure for organizing key domains across published implementation theories (1, 2). It is particularly well suited to technology evaluation because it addresses the complex, interacting, multi-level, and transient nature
of phenomenon in real-world healthcare settings. Teams of two researchers trained and experienced in qualitative interviewing conducted all interviews.

**Data Analysis**

From the survey data, we generated descriptive statistics to capture current EHR and HIE capabilities related to care coordination as well as the ability to meet proposed Stage 3 coordination criteria. From the interview data, we sought to understand how EHRs and other types of health IT were used to manage patient care across delivery settings, and identify opportunities for innovation in EHR design to support enhanced care coordination. Codes were developed a priori based on constructs hypothesized to be relevant based on the literature and were expanded as needed to incorporate emergent themes. Two researchers independently coded all transcripts and met to reconcile codes through discussion. Final coded transcripts were coded imported into Atlas.ti and analyzed to extract key findings after each phase of interviewing.

**Results**

*EHR Innovation to Improve Summary of Care Records (SCRs)*

Practices in the implementation sample had EHRs capable of generating Summary of Care Records, and most utilized the local health information exchange effort (Michigan Health Connect) to send them electronically during a referral by uploading the SCR to a portal. A common challenge was that SCRs contained a lot of superfluous information that was auto-generated by the EHR and this interfered with clinicians’ ability to locate relevant information. Primary care providers (PCPs) felt that specialists often missed important details relevant for the referral because they were so difficult to find in the SCR. As a result, one-third of practices inconsistently or never used the auto-generate SCR feature within their EHR.

Data from our statewide survey revealed varied opinions across PCPs as to which record elements should be shared when patients are transferred across care settings (Table 2). Practices in the implementation sample further explained that decisions about the relevancy of certain information also varied within provider, based on the patient, his/her history and preferences of the receiving physician. While federal criteria will dictate the types of information that must be shared to support transitions of care, our data point to the value of designing EHR functionality that enables more customization of SCRs.

</table>

Approximately one-quarter of implementation sample practices reported that their EHR currently included some functionality to customize SCRs, such as the ability to limit information by date range, check-boxes or radio buttons to deselect certain types of information, and/or templates to consistently pull the same information for specific specialists or referral types. A few providers also designed customizations with their vendor to have flexibility in structuring the document so that they could prioritize a concise narrative and emphasize the most relevant details. These features typically included moving the narratives to the front of the document and other visual cues (e.g. highlighting or bolding) to indicate importance.

Practices in the implementation sample felt that SCR functionalities could be further improved by enhancing usability and degree of available customization. For example, practices sought better filtering options to specify a more granular level of patient history to be included in the SCR while still meeting meaningful use criteria. Practices also felt that branching logic or guided workflows would make it easier to streamline the creation of customized SCRs.

Primary care providers valued receiving SCRs from specialists. However, they cited similar challenges in that the SCRs generated by specialists’ EHRs were often dense and obscured relevant new information. PCPs felt that SCRs that visually highlighted new or updated information generated during the referral would help them review the SCR and identify what to incorporate into their EHR.

**Current SCR Features Valued for Care Coordination:**
- Customization/electronic editing of information contained in SCRs through use of check-boxes, date range filters and templates
- Strategic location of concise narrative; reordering of SCR components to emphasize important information

**Future SCR Innovations to Enhance Care Coordination:**
- Ability to better filter information for a more concise and usable SCR, while still meeting meaningful use criteria
- Branching logic or guided workflows to facilitate customization of SCRs
- SCR generation from primary care to specialists: Functionality to visually or otherwise highlight most important pieces of information throughout the document
EHR Innovation to Support Team-based Primary Care Delivery

A broader set of policy efforts beyond meaningful use promotes enhanced primary care delivery models that have significantly increased care coordination and documentation requirements for primary care practices. In response, many implementation sample practices described transitioning to team-based care models that better utilize staff at different levels of training in order to meet patient care needs without additional physician burden. Implementation sample practices described a need for their EHR to better accommodate and support the documentation, workflows and necessary communication tools of multi-disciplinary care teams. Specifically, EHR innovations are needed that improve work coordination among staff and increase transparency of accountability when multiple individuals are providing care to the same patient.

The most common EHR feature used to support team-based care was tasking and task management. Over two-thirds of practices used tasking to track patient care needs as well as to delegate and follow up on staff responsibilities. Some EHR task features were more robust, allowing providers and staff to indicate status of a task, and run reports or receive alerts when tasks were incomplete. Many practices coupled this functionality with use of internal notes or messaging functions to create a record of task hand-offs and provide a communication space for shared understanding of responsibility. Having a team operate off of an assigned task queue served to coordinate tasks and also kept workloads open and transparent, providing accountability and ensuring tasks were completed in a timely way.

A small subset of implementation sample practices used embedded templates and clinical decision support features to facilitate greater autonomy and scope of work for non-physician staff. For example, templates and guided workflows with pop-up decision support helped one practice better utilize their nurses and mid-level staff in more enhanced care roles. Additional features, such as the ability to rank tasks by sensitivity or deadline, were requested by several practices. Practices also called for further EHR innovations to accommodate and integrate the workflow and documentation needs of ancillary team members, such as care managers, who are increasingly being incorporated into care teams.

Current Team-based Care Features Valued for Care Coordination:
- Robust tasking features with shared queues, direct assignment and alerts to identify incomplete tasks
- Plural patient record access to support concurrent workflows of team members
- Ability to electronically transmit notes to other team members within the EHR for improved communication
- Templates and guided workflows with clinical decision support to enable more delegation and greater autonomy to lower-level staff

Future Team-based Care Innovations to Enhance Care Coordination:
- Enhanced task functionality such as on-screen to-do lists and ability to rank tasks by sensitivity or deadline
- Functionalities to accommodate and integrate workflow and documentation needs of ancillary team members, such as care managers

EHR Innovation to Better Manage Patient Care in an Information-Rich Context

Richer information flowing between and within practices has the potential to enhance primary care provider decision-making and improve care coordination. In the absence of interoperability across EHR vendor systems, however, practices struggled to effectively manage this information and therefore felt they were not fully capturing the potential benefits of their EHR. EHR innovations to better manage patient care in an information-rich context fell into two areas: receipt of information and reconciliation of information.

EHR functionality for receiving information during patient care transitions

Referrals: All practices hoped that interoperability across EHR vendor systems would enable automated updating of information within their EHR. Specific to referrals, practices wanted their EHR to contain current referral status and
information from referral reports. Practices that were part of an integrated health system and on a shared EHR platform had these features and described more timely notification about referral status, and better integration of information from those encounters into their EHR.

Despite a lack of interoperability, some practices’ EHRs did a better job of supporting referral workflow and streamlining staff processes to better manage patients’ care transitions. For example, some practices used task lists or orders to track referrals or manage communication with specialists. These items were kept “open” in the EHR until the referral report was received. Staff found it particularly useful to be able to run reports on pending or overdue communication from the specialist regarding appointments or visit notes. Maintaining an accurate status of referrals, however, required substantial human-mediated communication with specialists.

Practices also requested better tools to incorporate information from external settings into their EHR in a consistent and easily accessible way. Providers were often unaware that new information was available because the EHR offered multiple options for where the information might be stored and it was not obvious when new information had been entered. Providers therefore failed to use documentation sent from external settings to inform care. Design elements such as the ability to tag or label documents for cross-listing in multiple places within the EHR would help providers more easily locate and utilize information.

Hospitalizations: Many practices relied on hospital portals to learn if their patients were hospitalized and to download documentation about their patients. Some practices received automated admission, discharge, or transfer (ADT) alerts, but felt overwhelmed by the volume of separate notices received throughout a patient’s hospital visit and post-hospitalization. Providers and staff were most interested in notice of admission and details contained in the discharge summary; intermediate notifications were considered less useful. Threading of hospital communications and ability to have EHR systems recognize and flag incoming communication by level of importance were therefore perceived as valuable.

**Current Data Management Features Valued for Care Coordination:**

- Ability for practices to run reports on pending or overdue tasks/orders to manage and close the loop on patient referrals

**Future Data Management Innovations to Enhance Care Coordination:**

- Automatic incorporation of referral reports, other incoming information, into relevant section of patient record
- Document tagging and/or ability to cross-list documents in multiple EHR locations for easier information retrieval
- More automation in closing out pending tasks/orders for completed referrals, e.g. when referral reports are scanned in
- Enhanced notification system for arrival of new information in the EHR, including ability to filter/sort by importance

**EHR functionality for managing information following patient care transitions**

Reconciliation: Practices struggled to incorporate large volumes of incoming documentation into their EHR. Practices expressed desire for auto-reconciliation features, with some automatic import and integration of data from hospitals and specialists. With the exception of labs and imaging, practices were still largely receiving read-only files – via fax, mail, or hospital portal download – that require scanning into the EHR. Even documents received electronically through the community HIE platform or via e-fax were still read-only documents; reconciliation therefore required a visual comparison of records with manual entry of new information.

A frustrating result of this process was multiple entries of the same (or similar) diagnoses or prescriptions that were entered into the EHR, cluttering the problem and medication lists. EHR auto-reconciliation functionality – the ability to support de-duplication or collapsing of similar entries to produce cleaner, more usable lists – was therefore perceived as valuable. Practices felt that the ability to easily tie ICD codes to entries within both the problem and medication lists would be one useful way to provide underlying structure for this functionality. Linking entries to the ICD coding classification system would also enable better organization of existing information within the record and provide the basis for enhanced interaction and safety alerts.
Some practices had the option to embed links to ICD codes using structured fields; however, practices reported inconsistent use of the functionality. Clinicians struggled to search underlying databases to locate and attach the appropriate ICD code; currently available software did not provide intuitive, comprehensive or consistently accurate ICD search capability. While auto-reconciliation of internal records with documentation from specialists, hospitals or third-party sources of pharmacy information is not possible in the absence of interoperability, practices felt that receiving incoming documentation with attached ICD codes would still provide value by aiding their staff in performing manual reconciliation.

**Acute vs. Chronic Documentation:** At least half of implementation sample practices described challenges related to accurate and efficient documentation of short-term, acute problems or medications in their EHRs. Providers sought EHR enhancements that would improve their ability to capture the distinction between active versus past medications, and acute versus chronic conditions when managing and sending out patient information. Lack of this functionality resulted in providers making documentation decisions likely to compromise patient care. For example, some practices chose not to enter acute problems, such as sinus infections, in the problem list to avoid clutter. This information may be valuable to specialists and without it providers may fail to identify chronic issues.

Several EHRs allowed providers to enter course of treatment information for prescriptions so that medications would automatically drop off of the “current” medication list. Providers valued drag-and-drop functionality and radio buttons to easily move entries between the active and past sections of problem and medication lists.

**Current Documentation Features Valued for Care Coordination:**
- Auto-removal of short-term medications from active medication list based on entered course of treatment
- Drag-and-drop or radio button features to easily move problems or medications to past information section(s)

**Future Documentation Innovations to Enhance Care Coordination:**
- Ability to attach ICD codes to problems and medications, enabling:
  - easier reconciliation
  - threading/grouping of similar issues
  - improved interaction alerts and decision support
- Tailored functionality for differentiating acute versus chronic problems and medications

**Discussion**

Despite significant increases in EHR adoption since the passage of HITECH, most primary care providers have little experience exchanging or using electronically shared clinical data to support care coordination and associated improvements in care quality, safety and efficiency. This study is one of the first to examine practices’ capabilities and use of EHRs and HIE to support care coordination in the context of proposed Stage 3 meaningful use objectives. Findings reveal key ways in which EHR and HIE functionality is already being used to support care coordination, and areas of opportunity for further innovation. Specifically, primary care practices called for improved availability and usability of features that facilitate (1) generation of customized SCRs, (2) team-based care approaches, and (3) management of the increased volume of electronic information generated and exchanged during patient care transitions.

Some of these innovations are likely much easier than others for EHR vendors to implement; for example, improved filtering mechanisms or highlighting functionality to improve SCR customization. Other innovations such as incorporating ICD codes into problem and medication lists may be more difficult to implement, or, in the case of widespread interoperability, are difficult for EHR vendors to tackle individually. For these, policymakers should consider including them in certification criteria, and, in parallel, consider creating communities of practice that enable EHR vendors to come together (perhaps with providers as well) and work to refine and specify the innovations. Policymakers and vendors must also remain cognizant of not just availability but also usability of different EHR features. Increased focus by developers on human-centered design methods and use of workflow analysis to inform the development of these enhanced EHR functionalities will be critical to realizing intended benefits of IT adoption.
Bolstered by Stage 3 meaningful use criteria and simultaneous delivery system reform efforts such as patient-centered medical homes and accountable care organizations, there will be increased pressure on EHRs to support improved care coordination. EHR vendors, guided by market demand and policy efforts, play a critical role in ensuring that practices have the technical capability – and usability – to enhance their care management practices. Beyond adding or enhancing system features, vendors are a key stakeholder in national conversations around achieving greater interoperability. Going forward, vendors and policymakers need to work in concert to create conditions in which all stakeholders see the benefit of and are willing to invest in robust information exchange capability in order to achieve optimal care coordination.

**Conclusion**

The ability of practices to effectively use EHRs and electronic information exchange to enhance care coordination practices is essential to translate the large national investment in health IT into improved care and patient outcomes. This study examines practices’ current capabilities and use of EHRs to support care coordination in the context of Stage 3 meaningful use objectives, with the specific goal of providing key recommendations for how to enhance EHR functionality. Vendors ultimately need to work with policymakers to find a viable approach to interoperability and create market conditions in which secure electronic sharing of patient information can be achieved to improve care coordination.

Abstract

Biomedical ontologies play a vital role in healthcare information management, data integration, and decision support. Ontology quality assurance (OQA) is an indispensable part of the ontology engineering cycle. Most existing OQA methods are based on the knowledge provided within the targeted ontology. This paper proposes a novel cross-ontology analysis method, Cross-Ontology Hierarchical Relation Examination (COHeRE), to detect inconsistencies and possible errors in hierarchical relations across multiple ontologies. COHeRE leverages the Unified Medical Language System (UMLS) knowledge source and the MapReduce cloud computing technique for systematic, large-scale ontology quality assurance work. COHeRE consists of three main steps with the UMLS concepts and relations as the input. First, the relations claimed in source vocabularies are filtered and aggregated for each pair of concepts. Second, inconsistent relations are detected if a concept pair is related by different types of relations in different source vocabularies. Finally, the uncovered inconsistent relations are voted according to their number of occurrences across different source vocabularies. The voting result together with the inconsistent relations serve as the output of COHeRE for possible ontological change. The highest votes provide initial suggestion on how such inconsistencies might be fixed. In UMLS, 138,987 concept pairs were found to have inconsistent relationships across multiple source vocabularies. 40 inconsistent concept pairs involving hierarchical relationships were randomly selected and manually reviewed by a human expert. 95.8% of the inconsistent relations involved in these concept pairs indeed exist in their source vocabularies rather than being introduced by mistake in the UMLS integration process. 73.7% of the concept pairs with suggested relationship were agreed by the human expert. The effectiveness of COHeRE indicates that UMLS provides a promising environment to enhance qualities of biomedical ontologies by performing cross-ontology examination.

Introduction

An ontology provides a formal description of entities (or concepts) and relationships between entities in a given domain. Ontologies or controlled terminologies in biomedical domains, such as the Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) and International Classification of Diseases, Ninth Revision, Clinical Modification (ICD9CM), play a vital role in healthcare information management. For example, SNOMED CT has been designated in the U.S. and many other countries as the preferred terminology for use of electronic health records (EHRs) [1]. Biomedical ontologies also serve as essential knowledge sources for many biomedical applications including text processing [2, 3], data integration [4, 5], decision support [6], reasoning [7], and information retrieval [8].

Most biomedical ontologies have a large size and a complex structure. It is unavoidable that errors and inconsistencies may be introduced. Hence researchers have proposed auditing methods to detect possible errors and inconsistencies in concepts or relationships to enhance the quality of biomedical ontologies. Jiang and Chute [9] leveraged Formal Concept Analysis to identify missing concepts in SNOMED CT. Zhang and Bodenreider [10, 11] proposed a lattice-based approach for exhaustive auditing of SNOMED CT structure. Gu et al. [12] presented computable methods to detect erroneous relationships in the Foundational Model of Anatomy (FMA). Luo et al. [13] developed an automated method to audit symmetric concepts in FMA using self-bisimilarity and linguistic features of the concept labels. Ochs et al. [14] presented a subject-based abstraction network method to audit SNOMED CT using the relationships provided. Mortensen et al. [15] evaluated crowdsourcing methods to detect errors in SNOMED CT. Zhang et al. [16, 17] developed fast MapReduce algorithms for lattice-based evaluation with dramatically reduced time. We refer to [18] for a more detailed review of early auditing methods for biomedical terminologies.

Most existing works have focused on developing auditing methods utilizing the knowledge (e.g., terms, relationships) provided within a targeted ontology. This paper proposes a novel cross-ontology method, Cross-Ontology Hierarchical Relation Examination (COHeRE), to detect possible errors and inconsistencies in hierarchical relationships across multiple biomedical ontologies in the Unified Medical Language System (UMLS) [19]. Inconsistencies uncovered using COHeRE involve UMLS concept pairs related by different types of relationships in disparate source vocabularies. For example, Prolonged depressive adjustment reaction is related to Adjustment disorder with depressed mood.
through the *is-a* relationship in SNOMED CT, while *Prolonged depressive reaction* is related to *Adjustment disorder with depressed mood* through the *sibling* relationship in ICD9CM (Figure 1). Since not all such relations can be correct, the inconsistencies provide immediate candidates for auditing and change. For example, the *sibling* relationship in Figure 1 should probably be changed to *is-a*, in ICD9CM.

![Figure 1: Example of inconsistent relations in SNOMED CT and ICD9CM integrated in the UMLS.](image)

COHeRE takes the UMLS concepts and relations as input, and produces inconsistent relations (and the number of distinct occurrences) as output. Within UMLS, 138,987 concept pairs were found to have inconsistent relationship types across multiple source vocabularies. 22,644 concept pairs were found to be related by *CHD* in some source vocabularies, but were specified as other relations (*RO*) in other vocabularies. 2,755 concept pairs were found to have the hierarchical child relation (*CHD*) in some source vocabularies, but being in a sibling relation (*SIB*) in others. Manual evaluation of 40 inconsistent concept pairs detected by COHeRE shows that 95.8% of the involved inconsistent relations indeed exist in their source vocabularies, and 73.7% of the concept pairs with suggested relationship by COHeRE are valid.

1 Background

1.1 Unified Medical Language System (UMLS)

The Unified Medical Language System (UMLS) [19], developed by National Library of Medicine (NLM), is a large integrated repository of biomedical source vocabularies to facilitate interoperability among disparate systems in medicine. Knowledge in the UMLS is organized by concept (or meaning). Term variants from source vocabularies are clustered together to form a concept, and each concept is assigned a unique concept identifier (CUI). For example, terms *Myocardial infarction*, *Infarction of heart*, *Heart attack*, *MI* and *Cardiovascular Stroke* from different sources represent the same meaning and are assigned a unique CUI: C0027051. The 2014AB release of the UMLS contains over 3 million concepts and 11.9 million unique concept names from more than 150 source vocabularies, including SNOMED CT, FMA, and ICD9CM. The concepts are provided in the distribution file MRCONSO of the UMLS.

Moreover, relationships between terms in source vocabularies are preserved in the UMLS as relationship attributes (RELA). There are over 600 relationship attributes in the UMLS, abstracted into 10 broader relationship types (REL). REL can be further classified as synonymous, hierarchical, or associative. For instance, *Coccyx Injury* (C0560630) and *Back Injury* (C0004601) are related through *is a* (RELA) in SNOMED CT. It is classified as a hierarchical relationship *CHD* (REL) in the UMLS, where *CHD* means child relationship. Table 1 shows the UMLS relationships (2014AB release) at different granularity. The 2014AB version of the UMLS contains over 60 million relations between terms, which are provided in the distribution file MRREL. In this paper, relationship refers to an individual link between two terms, while relationship indicates a type of relation.

1.2 MapReduce

We use a cloud-computing technique called MapReduce [20] in order to process large amounts of data required by COHeRE. MapReduce is a scalable distributed computing framework to process large amounts of data. A MapReduce program consists of a mapper and a reducer, to transform data in the form of key-value pairs. The mapper has a map method to transform input (*key, value*) pairs into intermediate (*key', value'*) pairs. The reducer has a reduce method to transform intermediate (*key', [value]*) aggregates into output (*key'', value'*) pairs. MapReduce has been successfully used for developing scalable approaches to auditing *is a* relationship in SNOMED CT [16, 17, 21, 22].

#### 2 Methods

Figure 2 shows the overview of the proposed pipeline of steps for COHeRE. First, the UMLS concepts and relations are taken as the input; relations are filtered according to certain criteria; and relations claimed in source vocabularies are aggregated for each concept pair. Second, inconsistent relations are detected if a concept pair has disparate relations in different source vocabularies. Finally, the inconsistent relations are voted by source vocabularies, and the voting result together with the inconsistent relations are the output.

![Figure 2: Overview of the proposed method COHeRE.](image)

#### 2.1 Relation Filtering and Aggregation

**Material preparation.** The MRCONSO (1.41GB) and MRREL (5.48GB) distribution files in the UMLS 2014AB release are used as the input for concepts and relations between concepts, respectively. Since UMLS is multilingual and covers a wide range of vocabularies, a subset of most relevant source vocabularies (Table 2) are manually selected to perform the cross-ontology examination for this study. Hence terms that are not in the subset of source vocabularies are discarded from MRCONSO. In addition, concepts with terms containing word *unspecified* or *NOS* (Not Otherwise Specified) are filtered out from MRCONSO, since such terms are very likely to cause error-prone relations in the integrated MRREL.

**Relation filtering.** Each relation record in MRREL can be represented as \((C_1, C_2, R, RA, S)\), where \(C_1\) and \(C_2\) form a concept pair, \(R\) is the relationship between \(C_1\) and \(C_2\) indicating \(C_2 \text{ R } C_1\), \(RA\) is the relationship attribute of \(R\), and \(S\) is the source vocabulary. Since every source relationship is represented in two directions in separate rows in UMLS, analyzing both directions of a concept pair is redundant. For example, if a concept pair \((C_1, C_2)\) is related through the \(CHD\) relationship with the *is a* relationship attribute, then \((C_2, C_1)\) is symmetrically related through the \(PAR\) relationship with the *inverse is a* relation attribute. To avoid duplicated analysis, only one direction \(CHD\) is used for analyzing this concept pair. Generally, concept pairs with relationship \(CHD, RN, SIB, SY, AQ\) or \(RO\) are used for the cross-ontology analysis. In addition, a concept pair is discarded if the concepts share the same unique identifier \(CUI\), since COHeRE will only investigate relationships between distinct concepts. Concept pairs with relationship attribute \(RA\) as *mapped from* or *mapped to* are also ignored, since they are generated by UMLS and represent mappings between source vocabularies. Due to the large size of the MREL file, this filtering process is implemented using MapReduce (Mapper in Figure 3) to enable parallel computing.

**Relation aggregation.** For each concept pair \((C_1, C_2)\), source relationships are aggregated into the format of

\[
(C_1, C_2) \rightarrow (R_1, RA_1, S_1) \mid (R_2, RA_2, S_2) \mid \ldots \mid (R_n, RA_n, S_n).
\]

---

1: **Input:** Relations in MRREL \( \{(C_1, C_2, R, RA, S)\} \)
2: **Output:** Aggregated relations by concept pairs:

\[
\{(C_1, C_2) \rightarrow (R_1, RA_1, S_1) | (R_2, RA_2, S_2) | \ldots | (R_n, RA_n, S_n)\}
\]

3: **class** Mapper
4: Setup a HashSet \( H \) and load it with all the relevant concepts in MRCONSO using DistributedCache.
5: **method** Map((\( C_1, C_2, R, RA, S \)))
6: if \( H \) contains both \( C_1 \) and \( C_2 \), \( C_1 \) and \( C_2 \) are not identical, \( R \) is not in \( \{CHD, RN, SIB, SY, AQ, RO\} \), and \( RA \) is mapped from or mapped to then
7: Emit((\( C_1, C_2 \)), (\( R, RA, S \)))
8: end if

9: **class** Reducer
10: **method** Reduce((\( C_1, C_2 \)), ((\( R_1, RA_1, S_1 \)), (\( R_2, RA_2, S_2 \)), \ldots , (\( R_n, RA_n, S_n \))))
11: Setup a HashMap \( M \) for source vocabularies and relationships.
12: if \( C_1 \) and \( C_2 \) are not multiply related for each source vocabulary in \( M \) then
13: Emit((\( C_1, C_2 \)), ((\( R_1, RA_1, S_1 \)), (\( R_2, RA_2, S_2 \)), \ldots , (\( R_n, RA_n, S_n \))))
14: end if

Figure 3: MapReduce algorithm for Relation Filtering and Aggregation.

Since COHeRE aims to audit ontologies utilizing external knowledge, \( (C_1, C_2) \) are discarded if they are multiply related in a single source vocabulary, that is, there exist \( i \) and \( j \) such that \( R_i \neq R_j \) but \( S_i = S_j \). For example, in the source vocabulary SNOMEDCT_US, concepts Acetaminophen (C0000970) and Acetaminophen 160mg/5mL elixir (C0973757) are related through two relationships: CHD (is a) and RO (has active ingredient). Such inconsistencies are discarded at the single source level. The relation aggregation process is implemented as a MapReduce Reducer in...
In sum, concept pair \((C_1, C_2)\) with relationship \(R\) and relationship attribute \(RA\) is filtered out if one of the following criteria is met:

- the relationship \(R\) is not \(CHD, RN, SIB, SY, AQ\) or \(RO\);
- the two concepts \(C_1\) and \(C_2\) share the same unique identifier \(CUI\);
- the relation attribute \(RA\) is mapped from or mapped to;
- if the two concepts \(C_1\) and \(C_2\) are multiply related in a single source vocabulary after relation aggregation.

### 2.2 Inconsistent Relation Detection

<table>
<thead>
<tr>
<th>No.</th>
<th>Concept pair ((C_1, C_2))</th>
<th>Relationships and source vocabularies ({(R, RA, S)})</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Arginine supplement (C3853287), Arginine and glutamine supplement (C3853286)</td>
<td>(CHD, is a, SNOMEDCT_US)</td>
</tr>
<tr>
<td>2</td>
<td>Hexosamines (C0019478), Fructosamine (C0060765)</td>
<td>(CHD, null, MSH \mid CHD, null, NDFRT)</td>
</tr>
<tr>
<td>3</td>
<td>17-Oxosteroid (C0000167), Androstenedione (C0002860)</td>
<td>(SIB, null, CPM \mid CHD, null, MSH \mid CHD, null, NDFRT)</td>
</tr>
</tbody>
</table>

Table 3: Examples of concept pairs after the Relation Filtering and Aggregation process.

For each pair of concepts obtained in the Relation Filtering and Aggregation step, the concepts are related either in a single source vocabulary or in multiple source vocabularies. For instance, the concepts Arginine supplement (C3853287) and Arginine and glutamine supplement (C3853286) are related through \(CHD\) only in a single source vocabulary SNOMEDCT_US (No. 1 in Table 3); the concepts Hexosamines (C0019478) and Fructosamine (C0060765) are related through \(CHD\) in both MSH and NDFRT (No. 2 in Table 3); the concepts 17-Oxosteroid (C0000167) and Androstenedione (C0002860) are related through \(SIB\) in CPM and \(CHD\) in both MSH and NDFRT (No. 3 in Table 3).

![Figure 4](image)

Figure 4: Decision tree for inconsistent relation detection using the example concept pairs provided in Table 3 as the input. The numbers in the curly brackets indicate the row numbers in Table 3.

Concepts pairs related in a single vocabulary are considered consistent (see the decision tree in Figure 4). For each concept pair with multiple source vocabularies, the concepts are either related through homogeneous relationships (e.g., No. 2 in Table 3) or non-homogeneous relationships (e.g., No. 3 in Table 3). Concept pairs related through homogeneous relationships are considered consistent, while those related through non-homogeneous relationships are considered inconsistent and collected to facilitate further analysis.

### 2.3 Relation Voting

The inconsistent concept pairs detected above have non-homogeneous relationships across different source vocabularies. A voting module is developed to rank the non-homogeneous relationships by the number of claimed source
vocabularies. If the relationship with the most votes has at least 2 votes, then it will serve as a suggestion for correcting potential errors in the inconsistent source vocabularies; otherwise, no suggestion will be made by COHeRE. Take row 3 in Table 3 as an example, the CHD relationship receives 2 votes from the source vocabularies MSH and NDFRT, and the SIB relationship receives 1 vote from the source vocabulary CPM. Hence CHD relationship could be suggested to correct potential error or inconsistency in the source vocabulary CPM. The output of COHeRE are the inconsistent concept pairs and suggested relationships with the most votes.

3 Results

After the Relation Filtering and Aggregation step, 11,921,502 distinct concept pairs were obtained. Among these, 11,372,069 pairs were related in a single source vocabulary, and 549,433 pairs were related in multiple source vocabularies. After the Inconsistent Relation Detection step, 138,987 concept pairs were found with inconsistent relationships across multiple source vocabularies. Table 4 shows the inconsistent relationships containing at least one hierarchical relationship (e.g., CHD or SIB) ranked by the number of concept pairs involved. For example, there were 2,755 concept pairs with inconsistent relationships CHD and SIB, and 1,407 concept pairs with inconsistent relationships CHD and SY. After the Relation Voting step, the concept pairs are classified according to the number of highest votes. Table 5 shows the numbers of concepts pairs with the highest votes between 1 and 7 with specific examples provided. For instance, there were 962 concept pairs with highest votes at least 3; 51 concepts pairs with highest votes at least 5; and there were no concept pairs with highest votes greater than 6.

Table 4: Inconsistent relationships with at least one hierarchical relationship (CHD or SIB), ranked by the number of concept pairs involved. Here CHD represents CHD with relationship attribute is a, CHD without relationship attribute specified, or RN with relationship attribute is a; and CHD with other kind of relationship attribute specified is explicitly provided in this table such as CHD (member of). SIB represents SIB with relationship attribute sib in is a or SIB without relationship attribute specified; and SIB with other kind of relationship attribute specified is explicitly provided in this table such as SIB (sib in part of). RO represents RO with any relationship attribute or without relationship attribute specified. RN represents RN with any relationship attribute or without relationship attribute specified. SY represents SY with any relationship attribute or without relationship attribute specified.

3.1 Evaluation

Since hierarchical relationships are dominant in biomedical ontologies, this study focused on evaluating two types of inconsistent relationships [CHD, RO] and [CHD, SIB] (see Table 4). A random sample of 40 UMLS concept pairs with inconsistent relationships (20 for each type) was selected and manually reviewed by a human expert. Table 6 summarizes the 40 concept pairs into 7 subtypes with examples given. For the [CHD, SIB] type, source vocabularies include MDR, NCI, ICD9CM, ICD10CM, SNOMEDCT_US, GO, FMA, and NDFRT, and the examined 20 pairs of concepts are regarding to disease, syndrome, injury, neoplastic process, cell component, pathologic function, or biologically active substance. For the [CHD, RO (has ingredient)] type, source vocabularies include NDFRT, RXNORM,

</table>

Table 6: Subtypes and examples of the 40 concept pairs with inconsistent relationships examined.

For each given pair of UMLS concepts, the expert was required to perform the following procedures:

(a) Check if there are terms mapping to them in each source vocabulary involved, and keep records of identifier codes for each term identified in a source vocabulary.

(b) For each relationship between the two concepts, check if the relationship is indeed claimed in the corresponding source vocabulary.

(c) For the relationship with the highest votes as at least 2, choose “agree,” “disagree,” or “not sure” to rate if the
expert agrees that it can be used as the correct relationship for the concept pair to resolve inconsistency. For the case that there is 1 vote for each relationship involved, specify one relationship as the correct relationship or answer “not sure.”

Take as an example the UMLS concepts \textit{Osteosarcoma metastatic} (C0278512) and \textit{Extraskeletal osteosarcoma metastatic} (C0855050) related through \textit{CHD (is a)} in NCI and SIB in MDR:

(a) Terms mapping to the concept \textit{Osteosarcoma metastatic} (C0278512) include C7781 in NCI and 10031246 in MDR. And terms mapping to \textit{Extraskeletal osteosarcoma metastatic} (C0855050) include C8808 in NCI and 10015849 in MDR.

(b) The relationships \textit{CHD (is a)} and \textit{SIB} between the two concepts are indeed claimed in NCI and MDR, respectively.

(c) The expert specifies that \textit{CHD (is a)} is the correct relationship.

The intention of steps (a) and (b) was to verify if the detected inconsistent relationships for the concept pair indeed exist in the source vocabularies or are caused by the integration process of source vocabularies into the UMLS. They are essential for evaluating COHeRE’s ability to filter out noisy information the integration of UMLS may cause and detect valid inconsistent relationships across different ontologies.

It was verified that all the 40 concept pairs have mapping terms in the involved source vocabularies. For a total of 95 individual relations (note that one concept pair have multiple individual relations in different source vocabularies), only 4 of them were found not claimed in the corresponding source vocabulary. For instance, the \textit{is a} relation between \textit{Metformin} (C0025598) and \textit{Metformin hydrochloride 1000 MG Oral Tablet} (C0978482) was no longer active in SNOMEDCT-US, but still included in the UMLS. In general, 95.8\% (91/95) of the individual relations detected by COHeRE is valid.

For cases where the relationship with highest votes is at least 2, there were 19 concept pairs, among which 14 (73.7\%) concept pairs were agreed by the expert, 2 disagreed, and 3 not sure. For the case that there is 1 vote for each relationship involved, there were 21 concept pairs, among which, 19 concept pairs were specified a correct relationship by the expert, and 2 not sure.

Manual examination of the verified result indicates the following facts:

- \textit{ICD9CM, MSH, and MDR} sometimes classify concepts related through \textit{CHD} as \textit{SIB}. \textit{Dermatitis Herpetiformis} (C0011608) and \textit{Juvenile dermatitis herpetiformis} (C0152092) are related through \textit{CHD (is a)} in SNOMEDCT-US, and \textit{SIB} in ICD9CM; \textit{Neurites} (C0085103) and \textit{Axon} (C0004461) are related through \textit{CHD} in GO and FMA, and \textit{SIB} in MSH; \textit{Ventricular Dysfunction} (C0242973) and \textit{Right Ventricular Dysfunctions} (C0242707) are related through \textit{CHD} in MSH, NCI, NDFRT, and SIB in MDR.

- \textit{SNOMED_CT} and \textit{NDFRT} show inconsistencies regarding to relations between pharmacologic substances and clinical drugs. For instance, the pharmacologic substance \textit{Buprenorphine / Naloxone} (C1169989) and the clinical drug \textit{Buprenorphine 8 MG / Naloxone 2 MG Sublingual Tablet} (C1168831) are related through \textit{CHD} in SNOMED_CT and NDFRT, and \textit{RO (has ingredient)} in RXNORM and VANDF. However, the pharmacologic substance \textit{Potassium Chloride} (C0032825) and the clinical drug \textit{Potassium Chloride 1 MEQ/ML Oral Solution} (C0979640) are indeed related through \textit{RO (has active ingredient)} in SNOMED_CT, and through \textit{RO (has ingredient)} in NDFRT. This indicates that SNOMED_US and NDFRT are inconsistent for relating clinical drugs with pharmacologic substances.

- \textit{SNOMED_CT} sometimes relates body parts using \textit{CHD (is a)} instead of \textit{part of}. For instance, \textit{Fifth lumbar vertebra} (C0223552) and \textit{Arch of fifth lumbar vertebra} (C0223553) are related through \textit{CHD} in SNOMEDCT-US, and \textit{RO (regional part of)} in FMA.

4 Discussion

\textbf{Distinction from related work}. COHeRE leverages the knowledge across different ontologies to detect possible errors, which is distinct from most existing OQA works utilizing the knowledge provided within a targeted ontology [9, 10, 11, 12, 13, 14, 16, 17, 21]. COHeRE also differs from [22], where the structural disparity between SNOMED CT’s Body Structure sub-hierarchy and FMA was investigated using a cross-ontology method, but the scope was limited to ontological terms relating to human body structure. In [23], Mougin and Grabar exhaustively studied multiply-related concepts within the UMLS, and explored why the multiply-related concepts occur and whether they are inherited from source vocabularies or introduced by the UMLS integration. It was reported that a quarter of multiply-related
concepts in UMLS are inherited from source vocabularies [23]. COHeRE differs from [23] in two ways. One is that COHeRE adopts only a subset of source vocabularies that are most relevant for cross-ontology examination. The other is that COHeRE aims to achieve effective filtering mechanism to remove the multiply-related concepts caused by the UMLS integration, and utilize the actual inconsistent relationships across multiple source vocabularies to detect inconsistencies and facilitate ontology quality assurance.

Conceptualization difference analysis. Manual analysis showed conceptual difference between ontologies. Take the concept pair Nipple neoplasm (C1112166) and Benign nipple neoplasm (C1332519) as an example, COHeRE detected two inconsistent relationships: CHD (is a) in the source vocabulary NCI, and SIB in the source vocabulary MDR. In NCI, Nipple neoplasm is classified into Benign nipple neoplasm and Malignant nipple neoplasm. In MDR, “neoplasm” is classified according to “benign,” “malignant,” and “unspecified.” Nipple neoplasm is classified under Breast neoplasms unspecified malignancy, and Benign nipple neoplasm is classified under Breast neoplasms benign. Hence the detected inconsistency is due to the conceptual difference. Although concept terms containing “unspecified” were filtered out by COHeRE, other terms classified under such terms were still included for the inconsistency detection (e.g., Nipple neoplasm under Breast neoplasms unspecified malignancy). To avoid this, the hierarchical information provided by UMLS (the distribution file MRHIER) can be used to remove the descendant terms of those terms containing “unspecified.”

Limitations. First, this study relies on the UMLS knowledge source, and it is not generalizable to domains lacking an integrated ontological system. Second, this study is limited in the number of concept pairs with inconsistent relationships evaluated. Third, this study only focused on evaluating two types of inconsistent relationships ([CHD, SIB] and [CHD, RO]). Evaluating more types of concept pairs may reveal more interesting inconsistencies. Fourth, this study did not investigate concept pairs that are multiply related in a single source vocabulary. It would be interesting to study inconsistent relationships occurring in a single source vocabulary. Lastly, if the ontologies integrated in UMLS are given in the Web Ontology Language (OWL) and the relations are defined as mutually exclusive, then simple OWL inferencing should be able to detect these inconsistencies.

5 Conclusion

This paper presented a novel cross-ontology method, COHeRE, to detect possible errors and inconsistencies in hierarchical relationships across multiple biomedical ontologies. COHeRE leverages the UMLS knowledge source and the MapReduce cloud computing technique for systematic, large-scale ontology quality assurance work. COHeRE is effective in detecting inconsistent hierarchical relations among UMLS source ontologies for quality assurance. The effectiveness of COHeRE indicates that UMLS provides a promising environment to enhance qualities of biomedical ontologies.

Abstract

Delivering genetic test results to clinicians is a complex process. It involves many actors and multiple steps, requiring all of these to work together in order to create an optimal course of treatment for the patient. We used information gained from focus groups in order to illustrate the current process of delivering genetic test results to clinicians. We propose a business process model and notation (BPMN) representation of this process for a Translational Pharmacogenomics Project being implemented at the University of Maryland Medical Center, so that personalized medicine program implementers can identify areas to improve genetic testing processes. We found that the current process could be improved to reduce input errors, better inform and notify clinicians about the implications of certain genetic tests, and make results more easily understood. We demonstrate our use of BPMN to improve this important clinical process for CYP2C19 genetic testing in patients undergoing invasive treatment of coronary heart disease.

Introduction

At The University of Maryland Medical Center (UMMC), the Translational Pharmacogenomics Project (TPP) aims to implement routine pharmacogenetic-based dosing and drug selection1. The first project has been to use CYP2C19 genotype test results to tailor antiplatelet therapy to cardiac stent patients. In this project, patients can be prescribed clopidogrel or alternative anti-platelet agents (e.g., prasugrel or ticagrelor) after cardiac stent implantation, based on their CYP2C19 genotype. Patients with loss of function variants in CYP2C19 are less responsive to clopidogrel and may be more effectively treated with alternative anti-platelet agents. To incorporate the use of genetic test results into routine clinical care, a multi-step and multi-actor process is necessary. There are many critical and time-sensitive steps required to deliver these genetic test results from the testing laboratory to the clinician. These results inform clinicians’ decisions to prescribe and dose anti-platelet therapy to a patient based on their genotype. Therefore, this information must reach the clinician in a timely manner. Genetic test results are not only time-sensitive but can be difficult to understand by non-genetics-expert physicians2, 3. This complex process may benefit from modeling methods to understand and improve internal workflow.

Workflow modeling is a useful tool in the ever-changing and fast-paced world of healthcare. All tasks in a healthcare system require standard processes, from patient diagnosis to treatment delivery4. Workflow modeling in healthcare serves to clarify the current processes that are being used as well as to illuminate potential improvements to those processes. For example, our team has previously used workflow models to document the overall implementation process for the UMMC TPP program5 incorporating Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines for CYP2C19 genotype and clopidogrel therapy5,6 into patient care.

There are many types of modeling languages and methods to illustrate clinical processes. Rad et al., identified requirements for healthcare process modeling languages: complexity, security and privacy, user understandability, optimized models for different purposes, evolution of processes, and nested processes and integration7. They also determined that, although no one modeling language will completely encompass and satisfy all the needs of a healthcare process, each language is useful for different modeling purposes. Our choice to use the Business Process Model and Notation (BPMN) stems from the need to

*These authors contributed equally to this manuscript.
understand interactions between multiple actors in our process. The process of delivering genetic test results to the clinician requires coordination by and interaction between at least five different groups of actors or entities: the testing laboratory, clinicians, the call center, the TPP research team, and the Electronic Health Record (EHR). Some of these actors or entities contain sub-actors, for example, departments of an organization. A BPMN, when applied to healthcare processes, helps us understand internal procedures in a graphical notation and communicate these procedures in a standard manner. Furthermore, we chose BPMN for its depiction of end-to-end flow of an entire process, which allows us to understand all interactions in the process.

Other studies have chosen workflow modeling as a method for assessment and improvement of healthcare processes. Shiki et al., demonstrated the ability to use Universal Modeling Language (UML) modeling to “clarify functions and extract typical processes” within a hospital-based cancer registry. After conducting interviews and observational surveys, the authors created process models using activity, use-case, and class diagrams. They concluded that modeling helps to analyze hospital-based cancer registration in order to identify specific departmental tasks and decrease task workload. Similarly, Askari et al., used UML activity diagrams to help improve a health care program in an elderly patient fall management case study. This program coordinated nine separate facilities with the aim of creating universal care for fall-prone patients. Activity diagrams were created from interviews with stakeholders that elucidated “essential sub-processes”, “information/data sources involved”, and “organizational aspects” of processes such as risk profiling and fall prevention intervention. The authors concluded that their modeling method allows them to describe and visualize patient care development, as well as identify shortcomings and propose solutions for program management.

To learn about and model the process of delivering genetic test results to clinicians, we conducted focus groups with clinicians with experience ordering the CYP2C19 genotyping test and the research team for the TPP Project. The goal for our focus groups to learn about processes for delivering genetic test results to clinicians is distinct from the our previous work using workflow models to document the overall implementation process for the UMMC TPP program in Shuldiner et al. With the information gained from focus groups in this study, we used BPMN modeling to identify areas to improve organizational and technical processes supporting the delivery of genetic test results in the TPP project. Furthermore, our work provides recommendations for the improvement of these processes.

Methods

Three two-hour focus groups were conducted in order to gain information and insight into the current process of delivering genomic test results from the testing laboratory to the clinician in two personalized medicine projects: the TPP and Personalized Diabetes Medicine Program (PDMP). Our first focus group comprised clinical research coordinators involved in both projects. The second and third focus groups involved clinicians from cardiology (for TPP) and endocrinology (for PDMP). Here, we describe findings from our first and second focus group that provide insight into TPP genetic testing processes specifically. Questions asked during the focus groups were related to three topics of interest: documenting genetic test results, notifying clinicians of those results, and viewing the genetic test results. Scripts for focus groups were developed with input from the research team, including members of personalized medicine projects to ensure appropriateness of questions for participants. Focus group sessions were audio recorded, transcribed, and coded by two authors using Dedoose, a qualitative research analysis platform. Our codebook contains terminology relevant to the three topics of interest (documenting, notifying and viewing genetic test results). The research team also decided to include codes relevant to user experience design (usability, missing functionality, problems and proposed solutions, and desired features). With these data, a BPMN model was created to document the current genetic testing processes. These models were used to capture the steps by which a genetic lab report moves from the testing laboratory to the clinician. To verify accuracy, provide completeness, and improve validity of these models, member checking was performed.
Results

Focus Group Participants and Setting

Focus groups were conducted between December 2014 and February 2015 at UMMC. Our first focus group had a total of four participants: one laboratory professional and three clinical research coordinators. The second focus group had five participants: three cardiology fellows and two nurse practitioners. All participants had previous experience with CYP2C19 test results.

Findings from Focus Groups: Current process could be improved to reduce errors and decrease workload

We found that the most important issue brought up in our first focus group with TPP research team members was that all parts of the current process are labor-intensive and potentially error-prone, with particular impact on research coordinators and testing laboratory personnel. Participants provided comments, identified problems and proposed solutions regarding the CYP2C19 testing workflow process (documenting, notifying, viewing). Additionally, the second focus group, comprising physicians and nurse practitioners, identified improvements with respect to clinician education, laboratory report design, and notification methods.

Documenting genetic test results in a lab report was the first topic covered with focus group participants (Table 1). We found that entering information into the laboratory report can be error-prone because the information must be entered manually multiple times throughout the process. Genetic testing is often performed in laboratories outside of the typical hospital laboratory. And, laboratory systems may be separate from the hospital EHR. This can lead to input errors, potentially impacting patient care. Another issue was the necessary availability of a credentialed laboratory director to sign off on a report. Within the current process, this person must manually sign off on all reports before they can be sent to the clinician and made available in the EHR. This task puts stress on the laboratory director, who may have other constraints on his/her time.

To address these issues, participants suggested that establishing electronic data transfer between testing laboratory and EHR clinical systems could help eliminate errors. Such data transfer could allow for reports prepared by laboratory professionals and documented in the lab system to also be resulted in the EHR and made available to clinicians in fewer steps. Ideally, such an interface between clinical systems would also allow a laboratory director to remotely sign off on reports. From the clinician perspective, we also identified a need to document additional information in order to better orient clinicians who infrequently order the CYP2C19 test. Specific recommendations were to: (a) include more information about the genetic test on the lab report such as information about the specific test and (b) provide easier access to relevant external resources and references to corroborate their treatment decision. More specifically, participants recommended the inclusion of references to current clinical studies about CYP2C19 to help make their treatment decision.

<table>
<thead>
<tr>
<th>Topics Covered</th>
<th>Issues</th>
<th>Proposed Solutions</th>
</tr>
</thead>
</table>
| Documentation of information in genetic test results in lab reports | • Information is inputted multiple times throughout the process  
• Documentation process is labor-intensive  
• A credentialed laboratory professional must be physically present to approve the report  
• Information included in the lab report is insufficient | • Access from the research genetic laboratory to the hospital via Laboratory Information Management System (LIMS). This will allow laboratory professionals to input information into this system and generate a report. The LIMS will then automatically fax it to the credentialed lab professional and, potentially, directly transport the report into the Electronic Health Record (EHR).  
• Provide a graphical representation of results in the lab report (e.g., table or chart)  
• Provide easy access to relevant electronic resources, literature, and clinical guidelines. |
The next section covered was the method to notify clinicians of test results (Table 2). Currently, there is no notification of results within the EHR. Participants proposed that an alert message in the EHR is the preferred method of notification. Effective clinical decision support (CDS) can help notify an ordering clinician when genetic information relevant to the drug is available. And, conversely, when the lab result is entered into the system, CDS can help identify when there is a potential mismatch between the patient’s genotype and a previously ordered medication. Participants also noted that the degree of urgency should be distinguished when clinicians are notified of results. Patients with percutaneous coronary intervention (PCI) often stay in hospital for less than 24 hours following the procedure. And, once anti-platelet medications are prescribed in the outpatient setting, ambulatory cardiologists and primary care physicians are less likely to interrupt treatment to make a change. We also found that notification methods could be improved. Currently, the testing laboratory pages the ordering physician who then has to call back to receive the primary (verbal) result. In addition to this problem, participants explained that, many times, the patient is not currently under the care of the test-ordering physician, who receives this page. This adds extra steps to the process so that the current care team can be notified and made aware of the test results. Participants recommended that this page-and-call system be replaced by a “smart” pop-up that could alert a clinician about test results. One clinician participant described his/her preferred frequency for such an alert to be “once for a particular user and not every single time [that user] logs in”. Another proposed solution was to create a subscription system through which multiple care team members would be made aware of test results. Finally, there was agreement among clinician participants that secure healthcare email was the preferred notification method. They noted that one email could convey all of the complex information set in a convenient format that is easily accessible.

| Methods of notification of available genetic test results | • Genetic testing often does not have discrete values that lend themselves to clinical decision support (CDS) alerts.  
• There is no active notification system in the EHR for this type of test result.  
• Critical test result notification systems are not tuned for genetic information. Some intermediate phenotypes resulted in excess contact to clinicians, even when the results did not change clinical practice.  
• Method of page-and-call is perceived as outdated and untimely  
• Over-alerting in the EHR remains a common complaint.  
• Identifying the correct physician for notification can be challenging in an area like interventional cardiology where physicians are often consultants to the primary care team, but primary care providers may not have experience with altering medications based on genetic testing. | • Implement an alert that is triggered when a physician begins the prescription ordering process for anti-platelet therapy that considers the patient’s genotype and the recommended drug and dosage.  
• Revise algorithm to discern “urgent” results from “non-urgent” results.  
• Email laboratory reports within a secured hospital system can relay more information and allow the clinician to read on their own schedule.  
• Implement an alert in the EHR that prompts the user once for a particular patient’s chart, when that chart is being viewed.  
• Provide a subscription system for notification of test results for the entire care team of a particular patient. |

The final topic covered, viewing genetic test results, is limited currently by the nature of the TPP Project (Table 3). Clinician participants expressed a desire to access the lab report and treatment recommendations in one document/screen. As a research project, however, treatment recommendations and interpretation of results are sent on behalf of the research team to the clinician. They are not available within the lab report.
We also found that the organization of the current laboratory report could be improved. Specifically, Clinician participants recommended a re-ordering of information in the report viewed in the EHR to include type of test ordered, results, and recommendations at the top of the page, with the supplementary information included underneath. Also, participants suggested that the visual appearance of the report to be rearranged to show a graphical representation of the test results to enable quick interpretation. When discussing the layout of the genetic test result, participants explained that the current report could be improved by placing the result of the test on the first page where it is viewed in the EHR. Currently, clinicians must apply an extra click to see the full report.

Workflow Model of Current Delivery Process of Genetic Test Results to Clinician

After analyzing qualitative data collected from TPP Focus Groups, we developed a BPMN model to document current genetic testing processes. Figure 1 illustrates these processes including the five actors and entities that work together to perform processes and complete the task. The five actors or entities include healthcare providers, the TPP research team, the patient medical records, UMMC laboratories, and the Translational Genomics Laboratory (TGL).

We found that certain redundancies appear in the process because there are multiple methods of notification. After the report is approved by the TGL laboratory director, there are four separate routes to deliver and notify clinicians of results (Figure 1A). For all CYP2C19 test results a paper copy of the test results are faxed to the UMMC clinical laboratory, manually entered into the EHR and can be accessed by a patients’ care team (Figure 1B), the TPP research team prepares a letter that includes both the test results and treatment recommendations and documents it in the patients’ paper chart, also accessible by the care team (Figure 1C). For actionable results, there are two additional routes of delivery and notification. Once test results are faxed to the UMMC laboratory call center center calls the ordering physician with actionable results (Figure 1D), the TPP research team also identifies the current care team and hand delivers the same letter that is documented in the patients’ paper chart (Figure 1E). A separate letter explaining test results is composed and mailed by the TPP research team to patients with actionable results (Not show in Figure 1).

Redundant delivery methods also lead to increased workloads for the TPP research team and unnecessary notifications for the clinicians. For example, added tasks are placed on the TPP research team in order to correctly identify the current care team of a patient. Figure 1F captures the issue of identifying the correct clinician to notify of CYP2C19 test results. In addition, only the ordering physician is notified by the UMMC laboratory call center of test results. Often, the ordering physician is not caring for the patient at the time results are available and is therefore incorrectly notified. The TPP research team has the added responsibility to identify and relay information to the correct care team members.
Discussion

Overall, we uncovered many areas for improving existing TPP genetic testing processes. Both focus groups raised similar issues. All participants agree that there are labor-intensive and potentially error-prone steps throughout the process, and insufficient support and resources to assist clinicians in treatment decisions. Furthermore, clinicians noted that the current report is not visually appealing or easily understood. We have identified clinicians’ needs from information gathered from focus groups. These needs can be addressed by the development of an improved workflow. First, clinicians need laboratory reports that are concise, easily understood and visually appealing in order to make clinical decisions based on test results. Second, clinicians also need to be able to access relevant electronic resources, literature, and clinical guidelines that will further aid in their decision. Third, we also found that a better process for making the laboratory report available to clinicians is necessary to reduce errors and the workload on laboratory technicians and directors. Added functionality, such as the ability of multiple clinicians to subscribe to a test result, is also necessary to alert all members of the care team of test results.

Our recommendations for solving these problems and meeting these needs include implementing clinical decision support (CDS) and establishing a Laboratory Information Management System (LIMS) capable of communicating (interfacing) with the EHR. With the addition of CDS in the form of alert messages and recommendations in the laboratory reports, clinicians will be more informed to make treatment decisions. The ultimate goal of our CDS recommendations is to notify the correct clinician and members of the care
team. These proposed improvements to the process have been combined to create a more optimal workflow model of the genetic laboratory result delivery process (Figure 2).

**Figure 2.** Proposed Workflow Model. Circles denote start and end of events, diamonds denote decision nodes, and rectangles represent tasks performed by the actors in that respective lane. Actionable results are defined as a patient genotype of “poor” or “intermediate” metabolizer. EHR, electronic health record; UMMC, University of Maryland Medical Center; LIMS, Laboratory Information Management System.

Clinical decision support has been included in the beginning of this process to automatically identify patients who are candidates for this type of genetic test (Figure 2A). Additional work is needed to establish automated approaches to identify patients eligible for CYP2C19 genetic testing. Previous work characterizing genetic information in US Food and Drug Administration (FDA) drug labels, for example, found there was little guidance for when to order a genetic test compared to guidance on how to use genetic test results once they are available. One approach has been to implement pre-test alerts recommending testing prior to prescribing were issued 1106 times for thiopurines and various drugs affected by CYP2C6 such as codeine.

We also recommend establishing a LIMS for the Translational Genomics Laboratory that can communicate with our EHR, allowing laboratory reports to be electronically transmitted from the LIMS and stored in the EHR (Figure 2B). Standards that set the language and structure of information are needed to ensure that information can be passed between the EHR and LIMS in a precise and unambiguous fashion. Most clinical systems and EHRs can send and receive clinical content as Health Level 7 (HL7) messages using HL7 and related standards. Establishing an HL7 interface between a TGL LIMS and the EHR would eliminate current steps to fax genetic test results from the TGL to the UMMC clinical laboratory, that are then manually entered into the EHR (Figure 1).

Further, a new LIMS has the potential to support linking with a knowledge base to augment information typically included in a laboratory reports. There is existing work, for example, developing the GenelInsight Suite to support laboratory and provider use of DNA-based genetic testing through the GI laboratory reporting tool for drafting informative reports on variants identified in patients, and the GI Clinic application for clinicians to access their patient’s genetic reports. It may also be possible to embed clinical
recommendations into lab reports. However, approval by an oversight committee would be needed (Figure 2C). Such an oversight committee might include individuals certified in clinical genetics, clinical cytogenetics, clinical molecular genetics, clinical molecular genetics and/or molecular genetic pathology (i.e., American Board of Medical Genetics and American Board of Pathology certifications) that are qualified to provide professional interpretation of test results.

Finally, CDS could potentially be included as an alert message to preemptively notify the care team that CYP2C19 results are available in the EHR to view (Figure 2D). An alert message, triggered by actionable CYP2C19 test results, for example might include both patient-specific results and treatment recommendations. There is existing work to implement CDS when genetic test results are available for patients. Studies have highlighted the need for point-of-care CDS to integrate clinically actionable results with the EHR\(^\text{15}\). Also, other studies have developed interruptive CDS alerts for at least eight genetic test results. These alerts are shown to be flexible with the types of information provided within them to allow for continual updating, as new information about the test in question is discovered\(^\text{16}\). Although the full laboratory report is also available, a pop-up notification with the necessary information will be more efficient for busy clinicians\(^\text{17}\).

**Conclusion**

By using BPMN to represent this complex process, we are able to see where crucial improvements can be made and where CDS could be implemented. BPMN serves as a learning tool to examine similar processes in other systems. This methodology allows for an effective modeling of a complex workflow. Through the identification of important actors, pathways, and problems in this workflow, an iterative improvement process can produce a more streamlined and efficient system.

Creating workflow models in the context of standard of care as we have here helps identify areas to improve processes. As the TPP project transitions from a study protocol to a routinely implemented clinical test, Figure 2 will serve as a document for discussing CYP2C19 testing processes without reliance on the TPP research team. This study is also part of a larger project to design and develop a software application to assist clinicians in making healthcare decisions based on genetic test results. These focus groups are the first in two rounds of focus groups. This first round has helped us to identify points in the current workflow that might be improved by such software. Where issues have been highlighted, improvements have been proposed for the current process of delivering genetic laboratory test results from the testing laboratory to the clinician in the TPP project at the University of Maryland Medical Center. Suggested improvements have the potential to reduce the number of actors in this process, improve the richness of the information transferred through the inclusion of decision support, and increase the overall efficiency of this process. These improvements are expected to improve patient care through the incorporation of genetic test results into routine clinical care, which will enhance physicians’ clinical decision making abilities and reduce the time between lab test completion and treatment delivery.

Abstract

The diagnosis of Alzheimer’s disease (AD) requires a variety of medical tests, which leads to huge amounts of multivariate heterogeneous data. Such data are difficult to compare, visualize, and analyze due to the heterogeneous nature of medical tests. We present a hybrid manifold learning framework, which embeds the feature vectors in a subspace preserving the underlying pairwise similarity structure, i.e. similar/dissimilar pairs. Evaluation tests are carried out using the neuroimaging and biological data from the Alzheimer's Disease Neuroimaging Initiative (ADNI) in a three-class (normal, mild cognitive impairment, and AD) classification task using support vector machine (SVM). Furthermore, we make extensive comparison with standard manifold learning algorithms, such as Principal Component Analysis (PCA), Principal Component Analysis (PCA), Multidimensional Scaling (MDS), and isometric feature mapping (Isomap). Experimental results show that our proposed algorithm yields an overall accuracy of 85.33% in the three-class task.

Introduction

Alzheimer’s disease (AD) is a genetically complex, progressive and fatal neurodegenerative disease, which leads to memory impairment and other cognitive problems1. There currently is no effective treatment that delays the onset or slows the progression of AD. According to the 2010 World Alzheimer report, there are an estimated 35.6 million people worldwide living with dementia at a total cost of over US$600AD billion in 2010, and the incidence of AD throughout the world is expected to double in the next 20 years2. Therefore, there is an increasing demand for diagnosing and treating AD. This paper focuses on the application of machine learning algorithms for Alzheimer’s disease diagnosis.

The diagnosis of AD is complex involving a variety of medical tests. These may include physical exam, neurological exam, mental status tests, and brain imaging, which will be used as a whole to assess memory impairment, judge functional abilities, and identify behavior changes, while ruling out other conditions that may cause symptoms similar to Alzheimer's disease. Current diagnosis of Alzheimer's relies largely on assessments of cognition and behavior, e.g. memory loss and behavior disorder, which start to decline in the later disease stages1,3. It is very difficult to treat neurological damage in current medical technology. Therefore, early detection of AD is of vital importance. Early detection of AD allows early treatment and thus help to delay the onset of AD symptoms, which could greatly improve the daily livings of patients.

There are many challenges in the early detection of AD. For example, it is very difficult to distinguish it from other types of dementia that begin in middle age, such as Pick disease. Another important thing that has to be mentioned is feature selection. A large amount of factors (e.g. biomarkers, metal status tests, etc.) contributes to the diagnosis of AD. It is very difficult to obtain the optimal set of discriminant features, which can best identify Alzheimer’s disease patients from healthy people or further classify different stages of AD. In this paper, we propose a hybrid manifold learning framework to embed multivariate feature vectors into a manifold, which preserves the pairwise similarity relationship. Some preliminary results are given. Generally speaking, our proposed algorithm consists of two parts, metric learning and manifold learning. Firstly, we utilize metric learning algorithm, i.e. Probabilistic Global Distance Metric Learning (PGDM)15, to construct a similarity matrix, which is then passed to isometric feature mapping (Isomap)13 to construct a manifold, which shows better discriminant property for Alzheimer’s disease recognition (i.e. disease diagnosis).

*Data used in preparation of this article were obtained from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu). As such, the investigators within the ADNI contributed to the design and implementation of ADNI and/or provided data but did not participate in analysis or writing of this report. A complete listing of ADNI investigators can be found at: http://adni.loni.usc.edu/wp-content/uploads/how_to_apply/ADNI_Acknowledgement_List.pdf
The remainder of this paper is structured as follows. In the Background section, we present a general review of the application of machine learning algorithms in Alzheimer’s disease diagnosis. Then, we narrow down to manifold learning algorithms. In the Methods section, we describe our proposed approach in detail, together with necessary supporting information. Detailed experiment setup is also given in this section. In the Results and Analysis section, extensive evaluation tests are presented to show the performance of our method. Furthermore, comparison is made with a wide range of modern manifold learning algorithms, i.e. as Principal Component Analysis (PCA), Multidimensional Scaling (MDS), and isometric feature mapping (Isomap). Finally, we draw conclusion and discuss about future work in the last section.

Background

Conventional manifold learning refers to “nonlinear dimensionality reduction methods based on the assumption that [high-dimensional] input data are sampled from a smooth manifold” so that one can embed these data into the [low dimensional] manifold while preserving some structural (or geometric) properties that exist in the original input space. Manifold learning is usually based on certain objective function. For example, PCA is designed to find the subspace with each dimension pointing to the direction with largest variance. By designing an appropriate objective function, it is possible to find a suitable manifold for AD diagnosis.

A large amount of work has been done on the application of manifold learning algorithms in the diagnosis of Alzheimer’s disease. The general idea is to design a manifold, which possesses more discriminant power in terms of classification tasks. Based on the whether a training set is needed, those approaches can be divided into two broad categories, i.e. unsupervised approach and supervised approach. For unsupervised algorithms, principal component analysis (PCA) was applied to the ADNI dataset for the early detection of AD in Lopez et al.’s work. Yang and coworkers utilized independent component analysis (ICA) to the MRI data in 2011. In 2011, Park proposed to use Multidimensional Scaling (MDS) to discriminate shape information between AD from normal controls. For supervised approach, it has begun to draw more attention due to its promising performance. It is usually formulated as prior information about the patient clusters, e.g. similar/dissimilar training set, which is similar to Xing et al.’s algorithm. Examples of this category are Wolz et al.’s neighborhood embedding approach and Shen et al.’s sparse Bayesian learning approach.

The progressive structural damage caused by AD can be noninvasively assessed by using magnetic resonance imaging (MRI) to measure cerebral atrophy or ventricular expansion. Therefore, many researchers have been focusing on MRI images, leading to massive application of image processing algorithms. Keraudren et al. proposed to localize the fetal brain in MRI using Scale-Invariant Feature Transform (SIFT) features. Suk et al. proposed a deep learning-based feature representation with a stacked auto-encoder, which combines latent information with the original low-level features.

Recently, researchers begin to use hybrid manifold learning algorithm to improve system performance. For example, Gray et al. reported to use the random forest algorithm together with MDS for multi-modal classification of Alzheimer’s disease in 2013. The algorithm introduced in this paper belongs to this category. Manifold learning algorithms are usually based on certain similarity metric. For example, the classical MDS was based on the distance matrix derived from L2 norm. Therefore, designing a proper similarity metric is of vital importance in the algorithm (Isomap for our proposed algorithm, and MDS for Gray et al.’s algorithm). Gray et al. improved the algorithm by utilizing the random forest algorithm as the first step to generate a better similarity metric, which is then passed to MDS for manifold construction. Random forest is based on decision tree, which is a ‘general purpose’ classification algorithm. The objective function is to maximize the classification accuracy but not to improve the similarity performance. In our proposed algorithm, we utilize Xing et al.’s metric learning algorithm to obtain an optimal Mahalanobis distance based on pairwise similarity prior knowledge. In other words, the learned distance yields small value for similar pairs and large value for dissimilar pairs, which is the optimization criteria of the algorithm. On the other hand, Isomap is developed based on the similarity graph of the data, which means the performance is highly dependent on the similarity measure. Therefore, an extra optimization step for optimal similarity measure is a straightforward approach to improve system performance.
Methods

In order to enact the model, we follow the description of our proposed algorithm below in Figure 1.

Figure 1. Schematic overview of the proposed methodology.

Our proposed algorithm is developed based on Isomap. In contrast to other nonlinear dimensionality reduction algorithms, Isomap can efficiently computes a globally optimal solution. Moreover, Isomap is based on the similarity graph calculated using certain similarity metric, which can be perfectly combined with metric learning algorithm. It’s because the direct input of Isomap is the optimal metric, which is different from many other algorithms. For example, PCA looks for the direction for maximum variance span of the high dimensional data, and ICA finds independent directions of the input data.

In classical Isomap, the Euclidean or Mahalanobis distance is used to construct the similarity graph, which is then used to construct the manifold. Therefore, an appropriate similarity measure is of vital importance. The probabilistic global distance metric learning (PGDM) algorithm is utilized to learn a robust metric, which is then used to construct a neighborhood graph. Then, the Isomap algorithm is utilized to learn the underlying global geometry of the data set. Finally, a support vector machine (SVM) classifier is trained for a three-class classification task.

Similarity metric learning

Distance metric learning aims to learn a distance metric (parameters) for the input data space from a collection of similar/dissimilar points that preserves the distance relation among the training data. In our present implementation, the probabilistic global distance metric learning (PGDM) algorithm is adopted. It is designed to learn a Mahalanobis distance which satisfies,

\[ g(A) = \sum_{(x_i,x_j) \in S} \|x_i - x_j\|^2_A - \log \left( \sum_{(x_i,x_j) \in D} \|x_i - x_j\|^2_A \right). \]  

(2)

where \(\|\cdot\|_A\) stands for the Mahalanobis distance; \(A\) is the Mahalanobis distance matrix; \(S\) and \(D\) are the similar and dissimilar training sets, respectively.

In our present implementation, we only study a simplified scenario, where \(A\) is diagonal. Then, Equation (1) can be solved by using the equivalent form,

\[ g(A) = \sum_{(x_i,x_j) \in S} \|x_i - x_j\|^2_A - \log \sum_{(x_i,x_j) \in D} \|x_i - x_j\|^2_A. \]  

(2)

We can thus use Newton-Raphson method to efficiently solve Equation (2)15.

It has to be noted that the Mahalanobis distance gives different weight to different dimensions, which is equivalent to feature selection. Lower weight indicates lower impact on the final result, i.e. similarity measure.

Manifold learning

The isometric feature mapping (Isomap) is a nonlinear dimensionality reduction method, which is also a low-dimensional embedding method. Isomap is used for computing a quasi-isometric, low-dimensional embedding of a set of high-dimensional data points. The algorithm provides a simple method for estimating the intrinsic geometry of a data manifold based on a rough estimate of each data point’s neighbors on the manifold.
Figure 2. Embedding multivariate medical records into a manifold.

As shown in Figure 2, the raw feature vectors are firstly transformed into similarity distance matrix (equivalent to neighborhood graph). According to the Isomap algorithm, the traditional MDS is then applied to the matrix to construct a manifold.

SVM Classification

In our present implementation, a support vector machine (SVM) classifier is utilized. It has to be noted that our focus is the construction of a better manifold which is more suitable for diagnosis. SVM is only implemented for demonstration purposes, which can be replaced by other algorithms, such as Neural Networks, nearest neighbor, etc.

An SVM is a high-dimensional pattern classification algorithm, which constructs a hyperplane or set of hyperplanes in a high- or infinite-dimensional space, which can be used for classification, regression, or other tasks. The data points are mapped so that the examples of the separate categories are divided by a clear gap that is as wide as possible. SVM can be formulated as

\[ \arg \min_{(w,b)} \frac{1}{2} \|w\|^2 \]
\[ \text{s.t. } y_i (w_i - b) \geq 1 \]

where \( w \) is the normal vector to the hyperplane; The parameter \( \frac{b}{\|w\|} \) determines the offset of the hyperplane from the origin along \( w \).

Results and Analysis

In this section, we first discuss the dataset that was used in the analysis. Then, we present the detailed experimental results for our proposed algorithm.

Data acquisition and pre-processing

Data used in the preparation of this article were obtained from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu). The ADNI was launched in 2003 by the National Institute on Aging (NIA), the National Institute of Biomedical Imaging and Bioengineering (NIBIB), the Food and Drug Administration (FDA), private pharmaceutical companies and non-profit organizations, as a $60 million, 5-year publicprivate partnership. The primary goal of ADNI has been to test whether serial magnetic resonance imaging (MRI), positron emission tomography (PET), other biological markers, and clinical and neuropsychological assessment can be combined to measure the progression of mild cognitive impairment (MCI) and early Alzheimer’s disease (AD). Determination of sensitive and specific markers of very early AD progression is intended to aid researchers and clinicians to develop new treatments and monitor their effectiveness, as well as lessen the time and cost of clinical trials.
The Principal Investigator of this initiative is Michael W. Weiner, MD, VA Medical Center and University of California – San Francisco. ADNI is the result of efforts of many co-investigators from a broad range of academic institutions and private corporations, and subjects have been recruited from over 50 sites across the U.S. and Canada22. The initial goal of ADNI was to recruit 800 subjects but ADNI has been followed by ADNI-GO and ADNI-2. To date these three protocols have recruited over 1500 adults, ages 55 to 90, to participate in the research, consisting of cognitively normal older individuals, people with early or late MCI, and people with early AD. The follow up duration of each group is specified in the protocols for ADNI-1, ADNI-2 and ADNI-GO. Subjects originally recruited for ADNI-1 and ADNI-GO had the option to be followed in ADNI-222. For up-to-date information, see www.adni-info.org.

We obtained MRI image data and diagnosis information from the ADNI database. We applied the proposed methodology to neuroimaging and biological data from 822 ADNI participants (229 normal patient, 405 MCI patients, and 188 AD patients). Each patient has three different high dimensional vectors of medical test data, corresponding to three distinct visits to the hospital. For example, for each visit there is a $p$-dimensional vector, corresponding to all the tests (totally $p$) done at that time. All MRIs were sagittal T1-weighted scans. The scans were collected using a 1.5 T GE Signa scanner with an MR-RAGE acquisition sequence.

We excluded all invalid records (with missing feature entries), resulting in totally 2158 high dimensional data points. Direct recognition using the 2158 raw data points based on the MRI images is very challenging, since it is very difficult to identify importance features. Therefore, instead of using the raw images, the MRI images are preprocessed by the CIVET software to get the brain volume information, such as volume for 3rd ventricle, 4th ventricle, right/left brain fornix, right/left frontal, right/left globus pallidus, right/left occipital, etc. A complete list of features used in this paper is given at my personal website17.

Experiment setup

As described in previous section, there are totally 2158 data points, with 586 normal records, 1006 MCI records, and 416 AD records. We randomly select 50 normal, 50 CI, and 50 AD data points as the testing set, leaving the rest (i.e. 536 normal, 956 MCI, 366 AD) as the training set (2008 training points and 150 testing points).

The training/testing set preparation process is repeated 10 times, which leads to 10 training/testing set combinations. For each training/testing set, our proposed algorithm is applied to construct a manifold, which is then passed to a SVM classifier for a three-class recognition task (Normal, MCI, and AD). Therefore, there are totally 10 set of recognition results. We use the sample code at the corresponding authors’ website for Isomap and PGDM implementation23. Relative improvement is defined as

$$R_{im} = \frac{r_p - r_t}{r_t} \times 100\%$$

where $R_{im}$ is the relative improvement; $r_p$ is the recognition rate of our proposed algorithm; $r_t$ is the recognition rate of the comparison target.

Experimental results

Figure 3 gives the error bar plot of experimental results for different conditions, i.e. average of 3 classes, normal, MCI, and AD. In order to eliminate the bias caused by training/testing set partition, we take the mean and variance of the recognition results. The error bars are calculated from the mean and variance of the recognition results from ten training/testing sets.

It can be seen that as the dimension of the manifold increases the recognition rate increases significantly. For example, in the 3-class recognition task, shown in Figure 3(a), the recognition rate increases from 33% at 1 dimensional feature to around 83% at 27 dimensional (or more) feature. Furthermore, at lower dimension (e.g. $<10$), the change of dimension number gives more impact on the final result, while at high dimension (e.g. $>10$) the performance improvement resulting from feature dimension increase becomes very small. As feature dimension changes from 1 to 10, the recognition rate increases by around 40% (from 34% to 80%). However, as feature dimension (i.e. the number of features) further increases, the recognition rate increases only 4% with fluctuation.
Based on one’s objectives, the optimal dimension number may vary. For example, if the objective is to classify if the patient is MCI, the optimal feature dimension can be chosen to 10. However, if recognition accuracy is the main concern, the optimal feature dimension would be around 25. In our present work, the optimal dimension is chosen to be 15 for a balance between recognition rate and efficiency.

Another thing that has to be mentioned is that the recognition results for MCI are much better than Normal and AD. This is due to the fact that we possess more MCI training materials (956 feature vectors) compared to 536 normal feature vectors and 366 AD feature vectors. More training materials yield better recognition results, which are consistent with the results in Figure 3. The Normal training records are more than AD, corresponding to higher recognition rate for Normal. The amount of training materials can be arranged according to special application purposes.

![Figure 3: Recognition results for different conditions.](image-url)

Table 1 gives the confusion matrix based on the experimental results in Figure 3. It can be seen that for MCI patients our proposed algorithm yields a very promising recognition rate, 98.4%, which means high sensitivity. However, the
misclassification rate (false positive) is also very high, i.e. low accuracy. This means our propose algorithm tend to misclassify other category as MCI (1 – 67.86% = 32.14%). The physical meaning is that for a patient with MCI our proposed algorithm can probably recognized the patient as MCI (98.4%, high sensitivity). However, if our propose algorithm classify the patient as MCI, there is 32.22% chance that the diagnosis is incorrect. In this case, 10.76% chance the patient is actually Normal, and 21.38% chance the patient is AD. For the other two categories (Normal and AD), the false positive rates are low. However, the recognition rates drop to 84% and 68.8%, respectively. This means if the recognition result is Normal or AD, it is very likely (> 98%) that the diagnosis is correct. However, there is less chance the algorithm will go to this category i.e. low sensitivity. On average, the proposed algorithm shows better performance at classifying Normal (high sensitivity 84% and high accuracy 98.59%).

Table 1. Confusion Matrix, feature dimension is chosen to be 30.

Comparison with other manifold learning algorithm

Extensive comparison is made state of the art manifold learning algorithms, i.e. PCA, MDS, and Isomap. Here, Isomap utilizes the L2 norm to construct the neighborhood graph. We also give the recognition result based on the original feature vectors, denoted as Original in Table 2. The raw data vectors are processed by mean and variance normalization before processed by each of the above mentioned algorithms. Table 2 gives the experimental results for all the comparison targets.

Table 2. Recognition results for comparison targets (%).

</tr>
<tr>
<td>Relative Improvement</td>
<td>-</td>
<td>1.21</td>
<td>1.00</td>
<td>1.40</td>
<td>12.28</td>
</tr>
</tbody>
</table>

It can be seen that our proposed algorithm yields much better results than all the comparison targets. The relative improvements are 1.21% over Isomap, 1.00% over PCA, 1.40% over MDS, and 12.28% over Original. The detailed recognition results for different conditions are visualized in Figure 4. Our proposed algorithm shows consistently better results than all the comparison targets. Since we have more MCI training materials, the corresponding MCI results are much better than the others, followed by Normal and AD.
Conclusion and future work

In this paper we propose a general framework for embedding multivariate medical records into a low dimensional manifold which possesses better discriminative property. This proposed algorithm is designed by the combination of two algorithms. We first construct a neighborhood graph based on a robust similarity metric, which is then used for manifold learning. It has to be noted that the PGDM algorithm is used to learn a Mahalanobis distance, which assigns different weights to different dimensions. This is equivalent to performing feature selection on the whole feature set. For example, in our present, the 23th feature (i.e. right globus pallidus volume) is given very low weight, which indicates that right globus pallidus volume is not suitable for the proposed classification task.

Our present study focuses mainly on the diagnosis of Alzheimer’s disease. We utilize all the features as a whole for the recognition task. However, it would be better if we can identify which feature is more important in identifying AD. The application of feature selection algorithms will help to further improve the performance of the proposed algorithm. Furthermore, our present work cannot predict the future tendency of a patient. Risk analysis of a patient in terms of developing Alzheimer’s disease will be our next step.

Extracting Characteristics of the Study Subjects from Full-Text Articles

Dina Demner-Fushman, MD, PhD, James G Mork, MS
National Library of Medicine, National Institutes of Health, HHS Bethesda, MD, USA

Abstract

Characteristics of the subjects of biomedical research are important in determining if a publication describing the research is relevant to a search. To facilitate finding relevant publications, MEDLINE citations provide Medical Subject Headings that describe the subjects’ characteristics, such as their species, gender, and age. We seek to improve the recommendation of these headings by the Medical Text Indexer (MTI) that supports manual indexing of MEDLINE. To that end, we explore the potential of the full text of the publications. Using simple recall-oriented rule-based methods we determined that adding sentences extracted from the methods sections and captions to the abstracts prior to MTI processing significantly improved recall and F1 score with only a slight drop in precision. Improvements were also achieved in directly assigning several headings extracted from the full text. These results indicate the need for further development of automated methods capable of leveraging the full text for indexing.

Introduction

Retrieval of publications for clinical decision support or database curation often relies on information about study subject characteristics. In publications indexed for MEDLINE®, this information is provided in structured, normalized form in Medical Subject Headings® (MeSH®) and can be easily used to find, for example, articles pertaining to preschool children or inbred mice. When this information is not available in structured form or directly stated in MEDLINE abstracts, it needs to be derived or extracted from the full text of the publications. The U.S. National Library of Medicine (NLM) Medical Text Indexer (MTI) tool1 that assists manual annotation of MEDLINE citations provided by the NLM Index section is fairly accurate in extracting and deriving some of this information available in the abstracts. For example, MTI achieves 93.84% F-score on assigning the heading “Humans”, whereas some other headings pertaining to study subjects are still far from this level of accuracy2. Indexers at NLM have access to the full text of an article, while only the title and abstract are provided to MTI. Over the years, Indexers have noted that specific detailed information about the study subjects that MTI missed was included in the full text of an article, but, not in the title or abstract. In this work, we present simple methods for extracting specific Mice and Rat strains, species, age groups, and gender from the full text of publications and explore if information extracted from the full text improves MTI performance for these headings.

Extraction of the subjects’ characteristics has been addressed in the past; mostly separately for clinical trials and for identifying animal species studied in the paper. For clinical trials, researchers are extracting such characteristics as the names and time points for primary and secondary outcomes, eligibility criteria and sample size. In the most common approach to extraction of the trials characteristics, the sentences potentially containing this information are identified first using statistical methods, and then knowledge-based methods are used to extract information. Xu et al. found candidate sentences in MEDLINE abstracts using HMM classifiers and then used syntactic parse patterns and rules to extract subject descriptors, such as man, elderly, diabetic, brain-injured; the study size (number of participants) and the studied disease3. Note that Xu et al. did not further separate subject descriptors by age, gender, or disease class. Similarly, de Bruijn et al. used an SVM trained on 78 full text articles to identify the most promising sentences and then applied simple extraction patterns and rules (called weak extraction rules) to identify over 20 trial characteristics, such as the enrollment start date and the experimental and control interventions4. The weak rules implemented in the ExaCT system5, in which the extracted text for each of the 21 trial characteristics were assessed by curators, corrected and then stored in the database, were sufficient for identifying the majority of trial elements in sentences recommended by SVM classifiers. Zhao et al. used Maximum Entropy classifiers to first assign sentences in a collection of 19,893 medical abstracts and full text articles to one or more of five classes: Patient, Intervention, Result, Study Design, and Research Goal6. Then the words in the sentences assigned to these classes were further classified as: Sex, Condition, Race, and Age. Two of these characteristics overlap with our targets: gender and age. In a 5-fold cross validation on 52 words in the Sex class, and 175 words in the Age class, Zhao et al. achieved 90% F-score for gender and 81% F-score for age extraction. Similarly, Kelly and Yang report perfect recall and precision for regular expression-based extraction of gender and age from 17 MEDLINE sentences containing information about the subjects’ age and 171 sentences with gender information7.
Several systems for identification of species in biomedical text are publicly available. Gerner et al. have developed a dictionary-based system LINNAEUS that was evaluated using MeSH species headings in MEDLINE citations, among other reference standards8. When using MEDLINE abstracts as input to the system, LINNAEUS achieved 52% precision and 68% recall. On the full text of the open access subset of PubMed Central, the system achieved 95% recall with a significant drop in precision to 13%. Naderi et al. have developed a hybrid rule-based/machine learning system, OrganismTagger9. Pafilis et al. have developed an open source SPECIES tagger, comparable in performance and faster than LINNAEUS10. As part of a large-scale multi-level event extraction effort, Pyysalo et al. achieved over 86% F-score extracting organism mentions, among other entities, using a single model that jointly predicts all entity types.11

In the previous work directly concerned with improving MTI performance, Jimeno-Yepes et al. compared extraction of MeSH terms from the abstracts, full text articles, and automatic summaries of different lengths12. For the headings addressed in our current work, the authors found that the machine learning methods currently implemented in MTI and trained on the abstracts have higher precision and somewhat lower recall than when summaries or full text are used as input. In this work, we continue exploring if the benefit of high recall offered by the full text of an article could be leveraged without significant losses in precision. Since the rule-base methods have shown high recall and precision in the previous evaluations discussed above, we start our targeted exploration of the study subjects’ characteristics with rule-based methods.

Our goals are threefold: first, we still do not have conclusive evidence that full text will significantly improve MTI performance on the headings pertaining to subjects’ characteristics; second, we would like to know if focusing on specific sections of the articles, particularly the methods section or captions will be more beneficial; and third, we would like to know if we should augment the original citations with the sentences extracted from the full text and then process these augmented citations using the MTI algorithm, or if we should directly assign the headings to citations using manually prepared lists of mappings of the extracted characteristics to MeSH.

In this work, we explored extraction of the following 29 MeSH Check Tags: Adolescent; Adult; Aged; Aged, 80 and over; Animals; Bees; Cats; Cattle; Cercopithecus aethiops; Chick Embryo; Child; Child, Preschool; Cricetinae; Dogs; Female; Guinea Pigs; Horses; Humans; Infant; Infant, Newborn; Male; Mice; Middle Aged; Pregnancy; Rabbits; Rats; Sheep; Swine; and Young Adult. We also explored all 51 specific strains of Mice and Rats under the Murinae [B01.050.150.900.649.865.635.505] 2015 MeSH tree, collectively identified as subject terms in this study. The specific Mice and Rat strains were included in our study because they are also typically mentioned in the full text of a paper and not in the title or abstract. Check Tags are a special type of MeSH term that is required to be included for each article and covers species, sex, human age groups, historical periods, pregnancy, and various types of research support (e.g., Male)13.

Methods

We used the 2014 MTI Test Collection that contains 143,658 citations randomly selected from the pool of citations indexed in the last year14. Of these, 14,829 (10.32%) full-text articles are available in the Open Access subset of PubMed Central15. We downloaded the articles in XML format and used the XML structure to evaluate extraction of the subject terms from various sections of the full text.

To identify the Methods sections that are most likely to describe the study subjects, we first extracted all section headings from the XML files. We then manually reviewed the names of the sections and the section titles and created a lookup list of the section names and titles most likely pertaining to Methods.

We then implemented a simple one-pass algorithm that parses the XML files, identifies candidate sentences using trigger words and extracts subjects’ characteristics from the candidate sentences. When the XML structure is parsed, information about the current section is stored and assigned to the sentences extracted from the section.

In the first step, the algorithm identifies candidate sentences potentially containing the subjects’ characteristics. Aiming for high recall, we qualify a sentence to be a candidate if it contains any members of the lookup lists or matches subject-related regular expressions described below. Using the section label, we determine if the sentence is found in the title/abstract, methods, caption, or anywhere in the body of the paper, excluding the abstract.
In the second step, the algorithm applies the gender and age extraction rules and looks up a MeSH heading corresponding to the list entry or the regular expression found in the sentence. We established the mappings for each entry and expression manually as described below. Finally, using the section label attached to each sentence we generate the following files for our experiments: subjectLinesMethods.txt (sentences extracted from the Methods sections only), subjectLinesMethodsCaptions.txt (sentences extracted from the Methods sections and Figure and Table captions), and subjectLinesBody.txt (sentences extracted from any section in the paper).

The final output of the algorithm consists of the sentences and information extracted from the sentences as shown in Figure 1.

![Figure 1 MeSH headings extracted from full-text sentences. The pipe-separated output presents: PMID; section of the full text (B stands for Body); strains and species headings; gender headings; age headings; and the sentence.](image)

**Dictionaries and regular expressions**

For identifying study subjects, their gender and age, we adapt the dictionaries and algorithms developed previously to identify patients’ characteristics in MEDLINE abstracts and clinical text. Briefly, our lookup list for human study participants consists of the manually curated concepts in the UMLS semantic type Population Group. We expanded the study subject list with case-insensitive regular expressions corresponding to MeSH entry terms for the animals in our subject terms listed above. For example, for Swine, we added to the list the following terms:

```
\WPig[s]?\W, \WHog[s]?\W, Phacochoerus, Suidae, and Warthogs.
```

For gender, we use two case-insensitive regular expressions:

```
\W(male[s]?|man|men|boy[s]?)\W and \W(female[s]?|pregnan[tcy]?|women|girl[s]?)\W. The second expression also extracts the Pregnancy heading.
```

Finally, for the subjects’ ages, we used both a lookup list of the terms in the UMLS semantic type Age Group and MeSH Age Groups and a set of regular expressions for identifying exact subject ages and ranges, for example,

```
(?:mean|M)?\W*age[d|s]?\W*?(?range|from)?\W+\W*?(?to)?\W*\W*?\W*?(?year|day|week) or \W*\W*?\W*?\W*?\W*?
```

We normalized the exact ages to MeSH terms in our list of subject terms using MeSH Scope Notes, for example, ages >= 65 AND <= 79 map to Aged.

**Evaluation**

The current abstract-based MTI performance for Check Tags and the specific Mice and Rat strains serves as comparison in all our experiments and the actual human indexing for these citations serves as the reference standard.

To evaluate the contributions of the specific sections, we extracted sentences and headings from the methods sections alone, from the methods sections and captions, and finally, from anywhere in the body of the paper, excluding the abstract.
We evaluated the contributions of the full text under two conditions: 1) adding candidate sentences to the titles or abstracts of MEDLINE citations and processing these extended abstracts using the current MTI algorithm, and 2) normalizing the characteristics extracted from the sentences to MeSH terms and directly assigning these subject terms to citations.

We used recall, precision and $F_1$ score as evaluation metrics. We computed recall as the proportion of the gold standard subject terms that were correctly assigned by our tools and precision as the proportion of the subject terms assigned by the tools that were correct. The $F_1$ score is the harmonic mean of recall and precision.

Results

The corresponding XML tags consistently identified the abstract, captions and the body of the paper. We found significant variations in the section naming, both in terms of the XML structure and the titles themselves. The structure was either providing the section name as an attribute of the section tag: for example, `<sec id="Sec2" sec-type="materials|methods">` or providing the name as title after the section tag, for example, `<sec id="Sec13">Participants</title>`.

We collected 163 section type variations for the Methods sections, such as: "intro|methods", "materials", "materials-methods", "material|methods", "method", "methods", "methods|conclusions", "methods|results", "methods|subjects", "subjects", "subjects|methods" and 116 titles, such as "Methodology", "Methodology and Findings", "Methodology and Principal Findings", "Methodology/Findings", "Methodology/Principal Finding", "Methods", "Methods Findings", "Methods and Findings", "Methods and Results", "Methods and design", "Methods and materials", "Methods/Design".

Table 1 presents the results of the evaluation of full text either added to the titles and abstracts or directly contributing Check Tags from our list of subject terms. The type, which sentence file was used, Recall, Precision, $F_1$, and the number of Check Tags matched to the human indexing are provided for each experiment. Files used for the experiments include: subjectLinesMethods.txt (1), subjectLinesMethodsCaptions.txt (2), and subjectLinesBody.txt (3).

</tbody>
</table>

Sentences extracted from the full text consistently increased recall in assignment of Check Tags, independently of the way they were used. In all cases we also observed a drop in precision, however, for the sentences extracted from the Methods section and added to the abstracts (bolded $F_1$ in Table 1), the drop in precision was relatively small and the $F_1$-score has increased compared to the MTI baseline. As the scope of the included text increased, the numbers of citations for which candidate sentences were found also increased from 2,696 for 20,813 sentences from the methods sections only, to 9,834 for 79,610 sentences from the methods sections and captions, and to 326,993 sentences from 12,800 citations when the whole paper was considered. The fact that 2,029 articles, for which we had no candidate sentences, include Check Tags in the reference standard indicates that our lookup lists were incomplete.
The direct assignment of the Check Tags produced mixed results. Table 2 shows the results for the individual terms compared to the current MTI baseline. Only 13 of the 29 Check Tags showed moderate improvements offset by significant degradation in performance for the remaining Check Tags. Notably, for all of the Check Tags that rely on simply finding a term in the sentence, there was a significant drop in the F1 score. The gender tags are an exception to this observation with a slight improvement for both Female and Male tags. There were three cases (bolded results in Table 2) where Precision, Recall, and F1 all improved for a Check Tag (Aged; Aged, 80 and over; and Cricetinae). The age tags that rely on both the dictionary terms and patterns showed improvement for the terms that do not occur in the text often and have to rely more on extracting the ages and mapping the numeric values to headings. For example, given the sentence “Separate analyses were conducted for children (age 6-11y), adolescents (age 12-19y), and for younger (age 20-50y) and older adults (>= 51y)”, our algorithm extracts the following tags: Chick Embryo|B|6100|Humans| Yound Adult; Middle Aged; Adolescent; Adult; Child. While Child (children), Adolescent (adolescents), and Adult (older adults) are mentioned directly in the text, based on the MeSH age range rules, we also included Young Adult (19-24) and Middle Aged (45-64).

Table 2 includes Precision, Recall, and F1 for both the MTI Baseline and the Full Text Check Tag results and a column showing the differences between F1 scores. Improvements with Full Text are highlighted in tan, and major negative results are highlighted in yellow.

Table 3 shows the results for 27 of the 51 specific strains of Mice and Rats where changes in performance were noted. The remaining 24 strains were not identified in the full text in this study and not included in Table 3. Similarly to the Check Tag performance in Table 2, we have mixed results for the specific strains of Mice and Rats as shown in Table 3. Only 12 of the 27 specific strains of Mice and Rats showed moderate improvements offset by significant degradation in performance for the remaining strains. Both “Rats, Inbred Lew” and “Rats, Zucker” (bolded results in Table 3) are cases where Precision, Recall, and F1 all improved from the use of full text. In the case of “Mice, Inbred SENCAR”, the results in Table 3 show no change in performance, but, in fact the full text provided 16 new cases of this term which were all incorrect.

Table 3 includes Precision, Recall, and F1 for both the MTI Baseline and the Full Text specific strains of Mice and Rats results and a column showing the differences between F1 scores. Improvements with Full Text are highlighted in tan, and major negative results are highlighted in yellow.

**Discussion**

Our first question – whether full text holds promise for improving MTI performance was answered positively, as we see significant improvements for thirteen Check Tags and twelve strains of Mice and Rats. The results also hint at the huge potential of full text with our highest recall of 86.42% compared to our MTI Baseline recall of 74.09%. Our results indicate however, that the simple methods that have been reported to show excellent results for extracting study subject characteristics lead to drop in precision for about half of the Check Tags and the specific strains of Mice and Rats. An example of such drop is the Check Tag *Horses* that relies on finding words *horse*, *horses* or *equus* in the text. It turns out, that the word *horse* occurs very frequently in the context of *horse serum* that...
is added as supplement to culture media. We will need to look at ways to improve our selection criteria and add filtering to reduce the false positives.

With respect to the second question, whether we should focus on specific sections of the articles, the differences in recall achieved when using the whole text and the Methods sections indicate that it might be more promising to focus on finding good candidate sentences anywhere in the text. Although the recall for candidate sentences was fairly high, our experiments indicated that our lookup lists are incomplete. Inspection of the full text of some of the articles from which no sentences were extracted showed that we systematically missed the age groups in the case reports for single patients because the terms man, farmer and woman were not included in our trigger terms. Generally, singular nouns were intentionally excluded from our trigger lists tailored for extracting characteristics of the subjects of clinical trials because for that task they often triggered false positives. Similarly, some age patterns are missing, for example, aged between \( d \) and \( d \) years. In some cases however, our algorithm will not be able to assign a Check Tag even if the trigger list is exhaustive. For example, the Check Tag Female was assigned to MEDLINE citation 23552690, however, the paper presents a study conducted on breast cancer cells and does not contain any gender-specific terms. It is quite possible that the specific cell lines discussed in the paper indicate that the tissues were female. If this assumption is correct, to assign the Check Tag to this article, we will either need to incorporate more domain knowledge or hope to find a sufficient number of examples for a machine learning algorithm. In the future, we will expand the lists using machine learning methods or manually inspecting citations that are indexed with Check Tags, but for which no candidate sentences were extracted using the current lookup lists. We also need to focus on identifying the higher quality candidate sentences to improve precision.

Our third question was whether we should add candidate sentences to the title or abstracts prior to MTI processing, or attempt to extract the subject terms directly using the simple mapping rules. The current results show that the answer for some of the age groups, strains of Mice and Rats, and gender might be to assign the subject terms directly, but for the majority of the tags augmenting the abstracts appears to be safer at the moment. Although the \( F_1 \) score is 1% higher than the current MTI baseline that supports the NLM Index section when the full text sentences are added to the abstracts, the corresponding 3% drop in precision indicates that we need to further explore how to use the full text.

Our work has the typical limitations of a feasibility study: we focused on testing the hypotheses rather than making sure that our trigger term lists are complete and all our extraction rules take into account the context surrounding the trigger terms. We chose to explore the hypotheses “breadth-first” exploring all parts of the full text, rather than following up “in-depth” with the very promising Methods sections results. These limitations also clearly define the future work that we plan to conduct shortly: expand the lists of trigger terms; maximize the benefits of using the Methods section; refine our extraction rules; and use the extracted sentences in weakly supervised machine learning experiments.

An additional consideration for pursuing methods based on the full text is its availability. MTI does not have access to the full text of an article at this time due to contractual reasons and only utilizes the title and abstract to produce its recommendations for the manual indexing performed at NLM. One possibility is to utilize the full text while it is available in memory for a relatively short period of time while it is being processed in the NLM Document Management System. To use the text in this short time, our algorithms need to be fast and at the same time offer significant benefits to justify the substantial efforts needed for including the full text in MTI processing. We hope that work like the research detailed in this paper will provide incentive for publishers to grant MTI access to full text in order to provide more complete recommendations for the MeSH indexing of their articles.

**Conclusion**

Our study shows that the full text of biomedical articles has potential to significantly improve automatic indexing of MEDLINE citations with MeSH headings pertaining to the study subjects’ characteristics. Furthermore, we show that simple rule-based methods significantly outperform the current automated indexing provided by NLM’s Medical Text Indexer for 25 of the 56 subject terms in our study, in some cases significantly better (Chick Embryo +45.47, Rats, Inbred Lew +42.86, and Mice, Inbred ICR +31.18). These encouraging results indicate we should continue exploring how to better use the full text for automated indexing of MEDLINE citations.

PHAST: A Collaborative Machine Translation and Post-Editing Tool for Public Health

Kristin Dew, MS¹, Anne M. Turner, MD, MPH, MLIS², Loma Desai, MBA³, Nathalie Martin⁴, Adrian Laurenzi⁵, Katrin Kirchhoff, PhD⁶
¹-⁶University of Washington, Seattle, WA, USA

Abstract
This paper describes a novel collaborative machine translation (MT) plus post-editing system called PHAST (Public Health Automatic System for Translation, phastsystem.org), tailored for use in producing multilingual education materials for public health. Its collaborative features highlight a new approach in public health informatics: sharing limited bilingual translation resources via a groupware system. We report here on the design methods and requirements used to develop PHAST and on its evaluation with potential public health users. Our results indicate such a system could be a feasible means of increasing the production of multilingual public health materials by reducing the barriers of time and cost. PHAST’s design can serve as a model for other communities interested in assuring the accuracy of MT through shared language expertise.

Introduction and Background
There are more than 300 languages spoken in the US, with approximately 25.2 million people having limited English proficiency (LEP), defined as a limited ability to speak, read, write, or understand English.¹ For LEP individuals, accessing accurate and up-to-date health information can be difficult. LEP status contributes to poor health literacy and to a greater incidence of health disparities, such as less preventative health screening.²⁻⁵

As providers of health care, public health departments are required by law to provide language appropriate materials for individuals who do not speak English.⁶⁻⁸ This includes translating health education materials, such as handouts, web resources, and flyers, into various languages used in the departments’ respective communities. Translations are typically performed in-house by bilingual employees, or ordered from professional translation vendors. The high cost of translations, whether commissioned through professional vendors or using limited bilingual in-house staff, limits the number and type of language translations produced. These constraints are particularly true for smaller health departments with limited resources and staff.⁹ Unfortunately, the decentralized organization of public health in the United States means that local health departments often use their limited funds to translate content similar to that of other health departments, because they lack systems for sharing translation resources.

Over the last four years, as part of an NLM-funded research project, we have been investigating the potential role of machine translation (MT), i.e. the fully automatic translation of text or speech from one natural language into another by a computer program, in producing multilingual public health materials,¹⁰ and how MT could be integrated in current public health practice.¹¹ In this paper we describe the design and evaluation of PHAST, a collaborative translation tool developed to facilitate the integration of MT into the typical workflow of public health practice (phastsystem.org). An early prototype of PHAST was described previously.¹² This paper describes additional design work, the updated PHAST system, and an evaluation via user testing with public health staff.

Our target population comprises lay users – bilingual public health professionals who have a deep understanding of their area of public health or a particular community they serve, but no formal linguistic or technological expertise. In our initial studies,¹¹⁻¹³ we found that core characteristics required of any MT system for public health materials include: 1) a simple, intuitive user interface to facilitate the various steps involved without extensive training or maintenance; 2) support for MT quality control via post-editing, i.e. the manual review and correction of machine-translated text; 3) document sharing among different health departments; and 4) a means for users to track the progress of their translations.

The technical progress in MT over the past decade makes such a system possible. MT has improved dramatically in the past 10 years. With statistical MT – which is presently the most promising approach – models are trained automatically using large bodies of parallel text or text in the source language paired with its translation in the target language;¹⁴ a more detailed introduction to statistical MT technology can be found in Canciedda et al.¹⁵ Statistical MT has been shown to be more powerful than older approaches like rule-based MT and translation memories, which rely on sophisticated linguistic analyses or on large databases of stored examples that need to match the input text.
Therefore, the best statistical MT systems typically outperform rule-based or example-based MT systems, even on specialized technical text (see e.g., Bojar et al.). However, statistical MT alone is still too full of errors to be used reliably for end-to-end translation, especially in sensitive domains like health. In applications where high translation accuracy is required, statistical MT is combined with a human post-editing step, i.e. human readers correct the translation errors created by the MT engine. The MT plus post-editing approach has so far been under-utilized by local and regional health departments. Our previous work was the first to demonstrate the feasibility and advantages of using MT plus post-editing in the public health domain.

In a study of Spanish MT plus post-editing for public health materials, documents blindly rated as equivalent in quality to a professional, manual, human translation could be produced for 5% of the cost using MT plus post-editing by a bilingual public health professional, based on an average public health professional’s wage.

MT is now in common use amongst translation vendors and in various business applications, but has been slow to be adopted into clinical settings. MT followed by human post-editing, or correction to the machine-translated output, can hold substantial time and cost gains over manual human-only translation. Even with the required step of post-editing, our prior studies have shown that MT could help public health workers create multilingual documents in less time and at dramatically lower costs. In blind ratings by public health professionals, post-edited MT translations were found to be equivalent to manual human translations. In tandem with document sharing, MT plus post-editing could ultimately help health departments produce a greater number of low-cost multilingual health materials.

The barriers of time and cost are compounded by a lack of coordination across health care authorities. Our prior studies of Washington (WA) State health departments found that translated health materials generated at one health department were rarely shared among other health departments. While there is a wide range of bilingual language expertise across health departments (e.g. interpreters, translators, community health workers, etc.), no single health department has the language coverage to meet their translation needs. There have been studies of collaborative translation by monolinguals with machine translation systems, whereby two non-bilingual people who use different languages collaborate to perform translation using MT services. As a novel approach to translation and current public health practices, we designed PHAST to enable the remote collaboration of health department workers in editing translated documents produced through MT. To the best of our knowledge, the way in which language expertise and translated documents are shared in PHAST has not been tried until now.

We describe here the design and evaluation of the PHAST tool. While PHAST was developed as a public health informatics tool, we believe it contains useful ideas for designing novel technologies for lay users in other governmental domains, creating collaborative translation applications, and bootstrapping low-cost MT applications.

Methods
Design
User-centered design is essential for increasing the efficiency with which users interact with MT systems. We relied on several common user-centered design methods to develop PHAST. Its initial design requirements stemmed from information gathered with qualitative methods, including interviews and focus groups, within five health departments in Washington State (see Table 1). We used the Cognitive Work Analysis framework to model current translation workflow as part of a larger project investigating translation practices in Washington State public health agencies. This was the basis of the step-by-step translation workflow used in PHAST, as well as the scenarios used in its evaluation. The workflow study was supplemented with feedback from state health department staff, preliminary usability testing with lay users, and post-editing studies, forming an iterative design and evaluation process that culminated with the evaluation described below.

While some materials may be specific to the local health department, more general health education information – such as those on vaccines, basic food safety, and so on – are frequently produced independently by each health department and remain in the gray literature. We decided to extend the design requirements for PHAST to include collaboration on producing and storing translations, in the hopes of allowing health departments to pool their bilingual staffs’ language expertise and their translated documents (see System Overview below).

We used the findings from our studies of public health translation processes and those of the subsequent post-editing studies to develop a translation system that is easy to use, efficient, and flexible, and that pooled limited bilingual public health staff language resources. The system is designed for lay users rather than professional translators. As such, its design deviates from that of traditional translation management systems: based on the results of our workflow
studies, we removed irrelevant features and created a step-by-step translation workflow mirroring that of health departments’ current practices. Because the public health translation staff frequently cited time and cost constraints, we attempted to create a lightweight, simple and intuitive design, which would remove the need for extensive training and minimize adoption headaches for staff; deployment would simply consist of staff signing up and undergoing brief training, for which we have prepared a tutorial.

To minimize costs, we created PHAST as a web-based application built on freely available tools and requiring only minimal maintenance costs and technical resources. PHAST was built online using the Kohana PHP Framework and a MySQL database. The front-end interface was built using JQuery, Twitter Bootstrap, HTML and CSS.

PHAST supports the following four main tasks that our workflow studies found to be essential for users: (1) uploading a text document requiring translation from the source language (English), (2) statistical MT translation, (3) human post-editing of the MT output to ensure quality, and (4) saving the original and post-edited text documents in an archive available for users to download either the original or complete post-edited version (see Figure 1). An important constraint is that PHAST only handles raw text, so figures, bullet points, images, and other formatting must be removed before uploading a document to the system. Uploaded documents are visible in the main archive and can be sorted by date or language. Any user can see the document’s post-editing status, which is tracked with a progress bar that is updated as each line break is completed (see Post-editing Interface section). When all lines have been saved, the document is marked with a green check, indicating that it is available for download.

Figure 1: Overview of documents and their progress through post-editing

Our prior studies of WA State health departments found that, in general, health materials generated at one health department were rarely shared among other health departments. The PHAST system applies a collaborative approach to encourage sharing of bilingual resources across health departments. Public health workers using the system can upload and post-edit documents from within their own department and can volunteer to post-edit documents that have been uploaded by other departments. Therefore, most of the cost of translation stems from the cost of the post-editor’s time. Sharing bilingual staff expertise allows collaboration amongst different departments in translating and sharing health materials. PHAST pools both language expertise and translated documents with the features described below.

When a user creates an account, their agency affiliation, language expertise, and information about experience level and professional certifications are saved in a profile. Once a user has a profile, she can upload a document in PHAST, which uses the Microsoft Translator API. PHAST covers all 39 languages supported by the Microsoft Translator API. At present we are using a free license with a limit of 2,000,000 characters per month. If PHAST were to be adopted widely, the modest monthly subscription cost of $40-160 (4,000,000-16,000,000 translated characters per month) would be one of the only recurring expenses to using the system. It is most likely that a central authority, such as the state health department, would act as a host institution for PHAST and pay the subscription cost; it is also possible that member departments would share the cost among themselves. In either case, the monthly subscription
fee is at the low end of the cost range for a single translation by traditional methods ($130-1220). Its breadth of supported languages, low usage costs, and translation quality are the main reasons we used Microsoft Translator API instead of the Google Translate API, though a system like PHAST could be built using either option.

A single source document can be added to the system and translated into multiple languages at once using the upload page. At present, PHAST only supports unformatted .txt and .docx files, because it uses PHPDOCX to convert documents into text format that is interpretable by Microsoft Translator. The upload page’s interface contains text entry fields for the document’s title, topic, intended audience, desired reading level, and other notes. Below these fields, the user selects the file to upload and checks the appropriate boxes next to the MT output languages available. The translated versions are then added to the pool of documents that are ready for post-editing (see Figure 1) and are tracked through the post-editing process. PHAST sends an email to users who have language expertise in the target language, notifying them that a new document has been added and is ready for post-editing.

Users can start post-editing by “claiming” the document, which prevents others from post-editing it simultaneously (see [1] in Figure 2), protecting their work and allowing for version control. Any user in the system can claim a document, allowing staff from one health department to add a document and bilingual staff from another to claim and post-edit the document. Because bilingual public health staff often have so many competing demands and perform translation work between other tasks, it may take them several post-editing sessions to complete the process, or they may need to hand the document off to someone else to finish the post-editing. They may also need someone else to perform a quality check of their work. By clicking the “unclaim” button, other users can access the document to revise or finish the post-editing (2).

Once a user initiates the post-editing process (see Figure 2), PHAST automatically separates the documents into segments based on delimiters (line breaks) in the source document (3). For each segment, the source text (4) is shown above its corresponding MT, which is now available for editing. When the post-editor has finished editing a segment, the user saves it (5), prompting the system to highlight the segment in green. During our interviews, we found that public health workflow requires intermittent post-editing and that staff require a method for easily saving their progress in order to resume post-editing at a later time. The “postedited” bar at the top of the screen tracks a document’s progress through the translation process (6), while the green highlighted sections remind post-editors which parts they have already worked on. The post-editing interface includes a discussion board where users can post comments about the document for reference (7). Our user interviews indicated that staff requiring a document translation may need to communicate particular instructions to the post-editors. For example, they could resolve disagreements about how to translate specific parts of the document.

Figure 2: Post-editing interface
Evaluation

We have studied the PHAST tool’s functionality and usability with public health department staff in Washington State. Prior to usability testing, we performed unit testing, whereby we tested the functionality of each feature in isolation; scenario testing, whereby we identified and performed a set of scenarios and verified that the system produced the desired output; and stress testing, whereby multiple users logged into the system at once and performed tasks with the desired outcome.

Before presenting our prototype to target users, we performed early usability testing with three bilingual volunteers who, like health department staff, were not professional translators. Appropriate changes were made and, when PHAST was determined to be ready for our target users, we presented it to a Washington Department of Health focus group comprising various health education and translation staff. Participants validated the translation workflow around which PHAST was designed, watched a demonstration of the system, and tested the main functions of the PHAST website. We noted critical incidences and user preferences to inform changes to PHAST. Once we made this series of initial changes, we performed formal user testing. Staff from two public health agencies in Washington were given scenarios based on the workflow findings and asked to perform a series of tasks that reflect the main PHAST functions and the typical translation workflow. Our one-on-one, in-person user tests with health department translation staff took place at their offices, on the current live PHAST website, phastsystem.org.

We would like to emphasize that fully testing the collaborative aspects of PHAST would require a complete deployment to several health departments. This would require a push from a state or federal authority, which was beyond the scope of this research project. Instead, we used a novel strategy for groupware usability testing to simulate two components of statewide deployment: the test scenarios and an analysis framework focused on evaluating collaboration. The test scenarios took users through the collaborative aspects of PHAST and encouraged them to think about performing each of the tasks within the context of inter-agency cooperation (e.g. “You want to leave the document for someone else to continue editing. How would you do that?”). As part of the analysis, we used Gutwin et al.’s mechanics of collaboration framework to evaluate how well PHAST in its current form supports collaboration.

In total, we completed the user tests with 10 staff members from two mid-sized health departments. All participants were involved in producing translated health materials in some capacity, but their job titles varied and included communications, education, nursing, and design roles. Their experience with translation work and technical expertise also varied widely; seven of the 10 had tried statistical MT systems, primarily Google Translate. Participants sat at laptops in their departments’ respective conference rooms to perform tasks and were video recorded to capture audio and actions on the laptop screen. In addition to the moderator, there was a note taker present for each session. Participants were asked to think aloud and were asked probe questions when appropriate.

For this reason, we did not report the time spent on each task. However, it is worth noting that the time required to complete all tasks ranged from around 7 to 28 minutes, depending on whether the users encountered difficulties and on the extent of the think-aloud commentary and probes. Data were collected on task success/failure; error count; error severity on a scale of 1-5, with 1 indicating completion with no problems and 5 indicating failure; as expected/not as expected statements; and perceived satisfaction, with 1 indicating completing the task with no problems and statements that it was exactly as expected or better and 5 indicating failure, with complaints.

The tasks were situated within scenarios based on our translation workflow findings and were read by the moderator. The scenarios emphasized the collaborative aspects of PHAST, in order to simulate realistic interactions across health departments that would likely occur if it were deployed widely. In order, the tasks were: login, identify who’s working on a document, identify the progress bar showing how complete the post-editing is, upload a document and fill in the metadata fields associated with it, claim a document, post-edit three lines of the claimed document and save them, identify the lines that have been edited and saved, leave a note for another post-editor in the discussion box, unclaim the document, and download a completed document. After each task, the moderator asked, “Is that what you would expect?”

Data Analysis

We analyzed the data by code in Excel (e.g., error count per task and participant) and with the code co-occurrence table feature in Atlas.ti, in order to find correlations between codes (e.g. claim a document and as expected/not as
expected). Three members of the study team used Atlas.ti to blindly code the videos. We used a closed codebook containing three main types of codes: codes for each task; codes for the aforementioned metrics that point to effectiveness, efficiency and satisfaction with PHAST; and codes for each of the mechanics of collaboration (explicit communication, consequential communication, coordination of action, planning, monitoring, assistance, and protection). Though some mechanics of collaboration were present across several tasks, such as coordination of action, we found planning to be too high-level for the purposes of evaluating PHAST, and therefore excluded it. We also coded suggestions and comments on heuristics. Open coding was encouraged for interesting quotes and additional themes, though it did not ultimately produce any useful findings. We merged the blindly coded Atlas.ti hermeneutic unit files and cleaned the merged version for overlaps and redundant coding.

Results

Participants voiced satisfaction with PHAST by indicating that each task occurred as they expected in the vast majority of instances, and four participants explicitly said they would like to use such a system. One of the less technically proficient participants, P5, told the moderator: “I just think it would be an incredible tool for us. And I like the fact that you have whatever document you have and that people can get on and they can claim it and they can do their thing and then they can unclaim it and someone else can go look at that. That’s very easy.”

About 66% of errors were concentrated in four of the ten tasks: uploading a document, claiming a document for post-editing, post-editing and saving three lines, and unclaiming a document. We also found errors in downloading a completed translation, but all were due to the participant not understanding the meaning of the term “download.” A summary of the errors by task and participant is in Table 1 below.

Table 1: Errors by task and by participant

The “uploading a new document” task had a high number of errors and two failures out of ten participant attempts. The errors were concentrated amongst the seemingly less technically proficient participants; four of the ten did not understand what “upload” means and needed prompts or further explanation to add a document to the system. Just over half of all errors were from two participants.

Claiming a document had the second-highest number of errors. While all ten participants completed the task successfully, five needed prompting. A majority voiced confusion over the need to claim the document before post-editing. We believe that this task has a high degree of trainability and that users would not have issues in subsequent attempts. Much of the confusion stemmed from the terminology of claim/unclaim; participant 10 said: “I’m not sure

497
that claimed is the best word. Probably like a library checked in and checked out... We use SharePoint here and I think that’s also a common terminology with SharePoint is checking out and checking in a document.”

The vast majority of failures stemmed from two of the users. Post-editing and saving a line had three failures, all of which stemmed from the participant not saving an edited line before moving on to the next. Identifying edited and saved lines also had three failures, one of which was due to not recognizing that the saved lines changed color. We believe this has a high degree of learnability and would not be an issue in repeated use. This task also evoked many suggestions for a track change feature or other ways to see what other post-editors have changed in the document. Unclaiming a document had two failures due to the users logging out or closing the window instead of clicking the unclaim button. This could cause critical bottlenecks to a translation’s progress through the system and will require design changes. A summary of the failures by task and by participant is in Table 2 below.

*Table 2: Failures by task and by participant*

To evaluate whether PHAST allows users to work collaboratively to complete common translation tasks, we plotted each of the mechanics of collaboration codes against the effectiveness (success/failure), efficiency (error count and severity) and satisfaction (as expected/not as expected and satisfaction 1-5) codes in Atlas.ti’s code co-occurrence table, in a novel groupware prototype evaluation method.\(^{27}\) The table gives a correlation coefficient that shows the degree to which two codes overlap. We used the table’s correlation coefficients qualitatively, as a way of finding themes by drawing attention to the extreme values, rather than as correlation coefficients per se. The login and download tasks were not considered collaborative enough for inclusion in this part of the analysis, so only eight of the ten tasks were analyzed. We also excluded the “planning” mechanic code, after deciding it was too high level for PHAST.

We found that PHAST adequately supports explicit communication, as embodied in the document upload and leave a note tasks. Effectiveness, efficiency and satisfaction were all deemed adequate because the positive codes (success, error 1-2, as expected, satisfaction 1-2) were the most strongly associated with the explicit communication code. The two upload failures were related to technical proficiency, rather than to any major design flaws, while all participants were successful in leaving a note for a fellow post-editor in the discussion box. Both tasks had high co-occurrence with positive satisfaction codes. Aside from leaving a note, all tasks included in this analysis involved consequential communication; the results for this code were thus somewhat mixed. The code co-occurrence table showed consequential communication to have a great degree of overlap with both success and failure codes. While there were 30+ errors in the tasks considered consequential communication, two participants accounted for more than half of them, so efficiency was also mixed. Satisfaction was high: the “as expected” code occurred with a much
greater frequency than “not as expected” and satisfaction scores 1 and 2 were the most frequently associated with consequential communication.

Similarly, the codes “coordination of action” and “monitoring” spanned all tasks included in this analysis. This is mostly due to the fact that the entire system and corresponding scenarios follow the translation workflow model, and these mechanics are embedded to some degree in every task. We found need for improvement in both, which is in line with our overall individual user experience findings. In terms of effectiveness, there were failures in seven of the eight tasks, with two or more each in uploading, post-editing, identifying edited and saved lines, and unclaiming. Coordination of action showed only moderate overlap with both success and failure in the code co-occurrence table. The success code was most strongly associated with monitoring, and failures had the third-strongest association. With regard to efficiency, there were 30+ errors, over the ten participants, in both coordination of action and monitoring, but the severity was relatively low and, as mentioned above, two participants accounted for more than half the errors. Satisfaction, on the other hand, was relatively high, with “as expected” and satisfaction scores of 3 and above being the most commonly associated with the coordination of action and monitoring codes.

PHAST has adequate support for assistance, which was practiced with the task of leaving a note in the discussion box. There were no failures (effectiveness) and no errors (efficiency), but participants made several suggestions for track changes or line-by-line commenting. Satisfaction was mixed, with “not as expected” co-occurring slightly more frequently than “as expected” and satisfaction scores mostly around 3.

Protection was part of all tasks except uploading a new document, and support for this code was mixed. There were seven failures, so effectiveness for tasks considered protection could be improved. Efficiency was mixed, with 24 errors but low severity ratings. Satisfaction was moderately high, with a greater frequency of “as expected” than “not as expected,” and a majority of satisfaction scores clustered around 1-3.

Discussion and implications for design

The usability testing findings indicate that PHAST could be successfully integrated in public health practice and that public health staff are receptive to using such a system. Still, additional changes should be made prior to any full deployment of the system. The vast majority of changes are relatively minor adjustments to the user interface, e.g., revising the use of claim/unclaim and prompting users to unclaim a document before logging out or closing the browser if they intend to stop post-editing at that time. These types of changes could increase PHAST’s usability and consequently improve its support for collaboration. Even with a design process that emphasized the needs of lay users, the findings show that the system could still be difficult for less technically proficient users in their first encounter. While we accounted for this with the step-by-step translation flow, highly learnable features, and design updates such as changing the upload page name from “Upload a document” to “Add new document,” there are limitations to how much the design can accommodate users unfamiliar with common terms such as “download.” Additional training may be required for these users.

In reviewing the findings and considering them in the context of our past and ongoing interactions with public health translation staff, we believe developing a way to better track changes or post-edited versions may be critical to the success of a full deployment. In the earlier workflow studies and in the post-editing tasks, public health employees voiced concern about quality assurance. This concern surfaced again during the user testing; one participant said, “My concern is that, will it save it as this is the change that I’ve made, but if somebody else didn’t want that change, the other version was still there... If I made a change and somebody else came back and said ‘Well what happened to my version?’ You know, I just think there needs to be some documentation there.” While quality assurance is also a concern with traditional translation vendors, our prior studies showed that health departments formed relationships with trusted vendors. A similar relationship could be built into PHAST with post-editor ratings by users. Post-editors would then have a greater incentive to produce quality translations and departments uploading documents would have more control over quality assurance. This addition would require careful consideration so as not to produce excessive demand for certain post-editors while discouraging others or damaging morale.

These concerns over quality assurance and respect for bilingual employees’ workload are compounded by the funding structure of local public health in the US, which generally occurs at the county or city government level and thus funding authority is highly decentralized. It would likely take a boost from a central authority to fully
implement and maintain PHAST in Washington State. To this end, we have built an ongoing partnership with the
Washington Department of Health, which has voiced interest in hosting and driving the adoption of PHAST.

Conclusion, limitations and future work

We have presented a collaborative MT system that can significantly reduce the time and cost of producing
multilingual health materials and was deemed usable by current public health staff. The system’s collaborative
aspects provide a new way to share limited translation and post-editing resources via a groupware system. We have
relied on user-centered design methods to iteratively develop PHAST and to better ensure that it meets the needs of
lay users and their work context; and usability testing results indicate that additional minor training would be
required only for the least technically proficient users. We identified design requirements that should be
implemented before attempting a full deployment, including additional quality assurance features. Offline support
policies, such as a partnership with a central authority that can help drive adoption, would also be necessary for full
implementation.

PHAST has been developed based on user studies with personnel from health departments in WA State. Our
findings may not reflect the practices of health departments in other states. A full evaluation of PHAST’s support for
collaborative work was limited by the fact that it was not yet fully implemented across health departments.
However, this provided an opportunity to simulate and then evaluate the system with the mechanics of collaboration
framework, which we believe to be a useful contribution to our study and to the public health informatics
community.

Statistical MT combined with post-editing has already been shown to reduce errors after machine translation is
performed. Currently, PHAST uses a generic MT engine (Microsoft Translator, (http://www.microsoft.com/en-us/translator/)). The Microsoft Translator Hub (http://hub.microsofttranslator.com/) allows users to train their own
customized models for a particular domain or style of text, provided they can supply a sufficiently large training set
(a minimum of 2000 sentences, though larger sets will yield better results). We have run initial experiments with
customized models produced by the Translator Hub, and we have found that the translation performance (as
measured by automatic evaluation procedures) is improved over generic models. A more widespread and regular
deployment of the PHAST system would enable the collection of a large number of examples of translated
materials, which in the future can be used to generate more accurate automated translation models. Thus, one of the
long-term goals of this work is to collect a sufficient number of quality translated documents to produce customized
translation models. Currently, the PHAST system does provide functionality for collecting documents it has
processed in a parallel text format, but the procedure for building new models has not been automated or integrated
into the PHAST system. This growing collection would allow future development of dynamic, customized MT in
the public health domain and could be replicable for other domain-specific MT systems.

Supervised learning is the dominant approach to automatic electronic health records-based phenotyping, but it is expensive due to the cost of manual chart review. Semi-supervised learning takes advantage of both scarce labeled and plentiful unlabeled data. In this work, we study a family of semi-supervised learning algorithms based on Expectation Maximization (EM) in the context of several phenotyping tasks. We first experiment with the basic EM algorithm. When the modeling assumptions are violated, basic EM leads to inaccurate parameter estimation. Augmented EM attenuates this shortcoming by introducing a weighting factor that downweights the unlabeled data. Cross-validation does not always lead to the best setting of the weighting factor and other heuristic methods may be preferred. We show that accurate phenotyping models can be trained with only a few hundred labeled (and a large number of unlabeled) examples, potentially providing substantial savings in the amount of the required manual chart review.

Introduction

Mining massive databases of electronic health records for patients who satisfy a set of predefined criteria is known in medical informatics as phenotyping. Phenotyping has numerous use cases: clinical trial recruitment, outcome prediction, survival analysis, and other kinds of retrospective studies [1]. Several translational science initiatives have made identifying patient phenotype cohorts from the Electronic Health Records (EHR) their primary focus. Among them are Electronic Medical Records and Genomics (eMERGE) [2], Pharmacogenomics Network (PGRN) [3], and Informatics for Integrating Biology and the Bedside (i2b2) [4]. Within each of these initiatives, disease-specific phenotyping algorithms are developed and run against repositories containing millions of patient records. The identified patient cohorts are subsequently linked to biobanks for genetic analysis.

Supervised machine learning is currently the predominant paradigm in phenotyping [1]. Unfortunately, supervised learning can be very costly due to the expenses associated with the manual chart review. A separate machine learning model is developed for each phenotype, typically requiring hundreds of manually labeled examples. For instance, about 600 hundred patient records had to be reviewed manually for each disease within the i2b2 initiative. At the same time, thousands more were left unlabeled. Investigating cheaper alternatives to supervised learning that take advantage of the bountiful unlabeled patient records thus holds great promise.

Semi-supervised learning is a class of methods that is concerned with incorporating unlabeled data within machine learning models along with the data that have labels. In contrast with the general domain, semi-supervised learning has not received sufficient attention in the clinical NLP community. In this paper, we report on our experiments with several versions of the expectation maximization (EM) algorithm [5], a simple, yet powerful approach for semi-supervised learning. We experiment with four phenotyping datasets developed within the i2b2 initiative and analyze the interaction between the key aspects of semi-supervised learning that determine its success: the amount of labeled and unlabeled data and the relative weight of the unlabeled data. For our experiments, we adapt and implement several flavors of the EM algorithm [6,7] for modeling the i2b2 phenotypes. We first experiment with the basic EM algorithm. While the outcome of this experiment is promising, it becomes clear that unlabeled data often overwhelms the model, resulting in suboptimal parameter estimates. This shortcoming is ameliorated by introducing the weighting factor, allowing the unlabeled data to help characterize the parameter space without overwhelming the relatively small number of high quality gold labels. We investigate several alternatives for setting the value of the weighting factor including cross-validation and a simple heuristic. We discover that cross-validation is not always the optimal approach with the competing methods often leading to better models.

Our results indicate that overall unlabeled data can be highly beneficial to the models. We show that high-quality models can be trained with only a few hundred labeled examples when combined with unlabeled instances, potentially providing large savings in the amount of the required manual chart review. We also discuss several
practical lessons that can be drawn from our experiments. Our work is a bid to bring semi-supervised learning to the 
attention of the community by detailing a simple yet versatile baseline method.

The only study we are aware of that touches the subject of semi-supervised learning in the context of clinical NLP is 
the work by Garla et al. [8], who look at an application of Laplacian SVMs for detecting the presence of malignant 
liver lesions. While this work presents an encouraging result, it has several shortcomings that make it difficult to 
predict how well their findings would generalize to other tasks. First, the liver lesion model is based on complex 
rule-based features, whereas our model utilizes a simple bag of Unified Medical Language System (UMLS) [9] 
features that are successful in phenotyping [1,10–12]. Second, Garla et al. do not examine the effects of varying the 
amount of labeled data, which in our work leads to valuable insights about the practical aspects of semi-supervised 
learning. Finally, Garla et al. study a single dataset, employing a model with a large number of tunable parameters. 
In contrast, our work involves multiple datasets, while utilizing a simple and scalable model with a single tunable 
parameter (the weighting factor), the effects of which we carefully study. While our experiments with multiple 
datasets paint a more complex picture concerning the effects of unlabeled data, our conclusions are likely more 
generalizable and complete.

This paper is organized as follows. We first discuss our models and the EM algorithm. We then outline an 
experiment providing the intuition why EM works. Next, we examine the effects of varying the amount of labeled 
and unlabeled data and different methods for setting the weighting factor. Finally, we discuss our findings and draw practical lessons from our results.

Methods

Data representation

We perform our study in the setting where the unit of phenotype classification is the complete patient chart. We 
represent each chart as a set of UMLS concept unique identifiers (CUIs) which we extract from the patient’s records 
using Apache Clinical Text Analysis and Knowledge Extraction System (cTAKES; ctakes.apache.org) [13]. CUIs 
are commonly used as representations in clinical NLP [12,14,15] as they help to abstract from lexical variability of 
medical terminology and capture the clinically relevant terms. Each CUI can be either asserted or negated, as 
determined by the cTAKES negation module. Some CUI examples employed in one of our models can be seen in 
Table 3.

Although cTAKES is capable of extracting most CUIs that exist in the UMLS, we only include the CUIs listed in 
phenotype-specific dictionaries. The dictionaries are created manually by i2b2 domain experts and define the 
relevant terms for each phenotype. Each phenotype-specific dictionary has \( D \) entries: \( CUI_1, \ldots, CUI_D \). We model a 
patient \( i \) as a \( D \)-dimensional vector of CUIs \( \mathbf{x}_i \) in which an element \( x_{ik} \) indicates how many times \( CUI_k \) from 
the dictionary was seen in the patient’s chart. Wu et al. [16] refer to this as “sum aggregation” and found it to perform 
well across performance metrics in a task requiring aggregating representations of patient charts.

Model

In the setting where all data have labels, model parameter estimation is fairly straightforward: for example, such 
methods as maximum likelihood or maximum a posteriori estimation can be utilized. When some of the labels are 
not known, parameter estimation is harder, although methods for obtaining parameter estimates exist. One such 
method is the Expectation Maximization (EM) algorithm [5]. The EM algorithm is an iterative procedure that begins 
by estimating model parameters from labeled data only. The model is then used to assign probabilistically-weighted 
class labels to the unlabeled instances. The model parameters are subsequently re-estimated from all (labeled and 
unlabeled) data and the procedure repeats until the parameter estimates stabilize. The algorithm is outlined in Table 
1.
• **Input**: labeled and unlabeled data
• Estimate model parameters from labeled data only (Equations 3 and 4)
• Loop until convergence
  o **E-step**: use current model parameters to compute the class distributions for patients with no labels (Equation 2)
  o **M-step**: re-estimate model parameters from both labeled and unlabeled examples (Equations 3 and 4)
• **Output**: model parameter estimates

<table>
<thead>
<tr>
<th>Table 1. Basic EM Algorithm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The probabilistic framework we utilize in conjunction with the EM algorithm is based on a multinomial Naïve Bayes classifier, an approach frequently used in the context of text classification [17]. Phenotyping is cast as a binary patient classification task where a patient ( x_i ) has a class label ( c \in {\text{case, noncase}} ). The total number of patients in the training set is ( T = T_{\text{labeled}} + T_{\text{unlabeled}} ), where ( T_{\text{labeled}} ) and ( T_{\text{unlabeled}} ) are the number of labeled and unlabeled examples respectively.</td>
</tr>
<tr>
<td>The posterior probability distribution over the labels for a patient ( x_i ) is given by Bayes rule:</td>
</tr>
</tbody>
</table>
| \[
    p(c | x_i) = \frac{p(c)p(x_i | c)}{p(x_i)} \quad (1)
| |
| Incorporating the standard Naïve Bayes assumption, this equation can be factorized to include class-specific CUI distributions \( p(\text{cui}_k | c) \) and the prior class probabilities \( p(c) \) as model parameters: |
| \[
    p(c | x_i) = \frac{p(c) \prod_{k=1}^{D} p(\text{cui}_k | c)^{x_{ik}}}{\sum_{c' \in \{\text{case, noncase}\}} p(c') \prod_{k=1}^{D} p(\text{cui}_k | c')^{x_{ik}}} \quad (2)
| |
| The parameters of this model can be computed using maximum a posteriori estimation: |
| \[
    p(\text{cui}_k | c) = \frac{1 + \sum_{i=1}^{T} x_{ik} p(c | x_i)}{D + \sum_{d=1}^{D} \sum_{i=1}^{T} x_{id} p(c | x_i)} \quad (3)
| \[
    p(c) = \frac{1 + \sum_{i=1}^{T} p(c | x_i)}{2 + T} \quad (4)
| |
| Notice that the generative model that gives rise to these equations assumes that the patients are generated from a mixture of two components that correspond to the two classes (case and noncase). These assumptions are likely to be violated in practice. The patient pool used for selecting the data to be labeled could potentially contain patients with other medical conditions whose class-specific CUI distributions could not be captured well by model parameters \( p(\text{cui}_k | c) \). It could also be that the “natural” (highest probability) clustering of the data does not fit well into the case/noncase class boundaries we adopted for the phenotyping task. Depending on the extent to which the modeling assumptions are violated, the unlabeled data could prove to be detrimental to the performance of the model. In order to alleviate the negative impact of the violated assumptions, Nigam et al. [7] augment their model with a parameter \( \lambda \) that determines the contribution of the unlabeled data. We investigate several strategies for setting this parameter and their effect on the quality of the ensuing model. |
| The augmented version of EM is written as follows. We first define \( \lambda_i \) to be the weighting factor \( \lambda \) for the unlabeled examples and 1 for the labeled examples. We then rewrite the model parameters as follows: |
| \[
    p(\text{cui}_k | c) = \frac{1 + \sum_{i=1}^{T} \lambda_i x_{ik} p(c | x_i)}{D + \sum_{d=1}^{D} \sum_{i=1}^{T} \lambda_i x_{id} p(c | x_i)} \quad (5)
This augmented EM algorithm is identical to basic EM in Table 1 except Equations 3 and 4 are swapped for Equations 5 and 6 respectively. The weight of the unlabeled data \( \lambda \) can be set via n-fold cross-validation, splitting the labeled data into a training and test sets and attempting different values of lambda. In addition to cross-validation, we introduce a heuristic that sets the weighting factor using a simple equation:

\[
\lambda = \frac{1}{T_{labeled}} 
\]

The rationale for this heuristic is the following: the model should be able to obtain accurate parameter estimates from the labeled data alone, when a large amount of it is available. Thus the weighting factor should decrease as the amount of labeled data increases.

Datasets
We utilize four datasets all of which were created within the i2b2 initiative [12,15,18,19]. We show various important characteristics of our datasets in Table 2.

Table 2. Phenotyping datasets used in the experiments.

Domain experts defined the ICD-9 codes relevant for each phenotype. These were then used to create the initial cohort from more than 6 million patient EHRs of the Partners Healthcare System. From that initial cohort, about 600 patients were randomly chosen for manual labeling. Each patient chart was reviewed by a domain expert and labeled at the patient level.

Obviously, only a small portion of the initial cohort could be labeled manually, leaving a large number of unlabeled examples for our semi-supervised learning experiments. For each experiment, we sampled randomly 500, 1000, and 3000 patients from the portion of the cohort that was never labeled.

Experimental Setup
The main objective of our evaluation is to determine whether unlabeled data can improve the classification accuracy of supervised models. The most natural baseline in these circumstances is, therefore, a supervised learning baseline in which the models are trained using labeled data only. During evaluation, we examine the behavior of semi-supervised learning with respect to the supervised baseline. This type of evaluation is best conducted via an analysis of learning curves as this allows us to compare the performance of supervised and semi-supervised models at different sizes of the training set.

To generate smoother curves, we utilize 10-fold cross-validation. In a typical experiment, within each fold we allocate a held-out test set and a pool of examples from which the labeled data is sampled. To produce a single point on a learning curve, we average the performance on the held-out test sets across all folds. To produce a point on the baseline curve, we train a Naïve Bayes classifier using labeled data only and evaluate its performance on the held-out test set. To produce a point on the semi-supervised learning curve, we add the unlabeled data, run the EM algorithm for 25 iterations\(^1\), and use the resulting model to classify the test set. The resulting curves can be

\[^1\) In our preliminary experiments, EM typically converged after 15-20 iterations.
compared visually or numerically in terms of the area under the curve (AUC) or increase in accuracy. For each phenotype, we generate the supervised baseline and semi-supervised learning curves for 500, 1000, and 3000 unlabeled examples.

We first experiment with the basic EM algorithm, which could also be viewed as a version of the augmented EM in which the weight of the labeled and unlabeled examples is the same. To illustrate the inner working of the EM algorithm, we examine the feature weights across EM iterations. Next, we experiment with augmented EM, down-weighting the unlabeled examples. Finally we experiment with setting the weight parameter using our heuristic technique and 10-fold cross-validation. During cross-validation, the held-out test set is, of course, not used; instead a validation set is allocated within each fold and each of the following lambda values is evaluated: 0, 0.05, 0.25, 0.50, 0.75, 1.0.

Due to the limit on the number of figures, we are not able to provide individual learning curves for the four phenotypes for all experimental conditions. Instead, we summarize each condition by plotting the curves that are averaged across all four phenotypes. These plots are supplemented by individual phenotyping plots for several important experimental conditions. All experiments reported in this paper are based on our own implementation of the EM algorithm and the supervised baseline.

Results
The averaged learning curves obtained in the experiment with basic EM algorithm are shown in Figure 1 (upper left).

![Learning Curves](image)

Figure 1. Average Learning Curves

The individual learning curves for each of the four phenotypes are in Figure 2. To take a peek “under the hood” of the EM algorithm, we train a Crohn’s Disease model using 10 labeled examples. The top ten features selected using log-likelihood ratio are shown in the first two columns of Table 3. The top ten features selected using log-likelihood ratio after running EM for 25 iterations with 3000 unlabeled examples are in the last two columns of Table 3.

Table 3. Top ten features before and after execution of EM for Crohn’s Disease. The ‘-’ preceding the CUI indicates negation.

The results of running the augmented EM algorithm with $\lambda$ set to 0.05, 0.20, and 0.50, are in the bottom row of Figure 1. We also provide the individual learning curves for $\lambda=0.05$ in Figure 3. Finally, the results of using our $\lambda$ selection heuristic and 10-fold cross validation are shown in Figure 1 (top middle and top right); the individual phenotype learning curves for these conditions are also available in Figures 4 and 5 respectively.

One way to summarize these plots numerically is to examine the difference in the area under the curve (AUC) between the learning curve of a semi-supervised approach and the supervised baseline. Another is to compute the average improvement of a semi-supervised learning curve over the learning curve for the supervised baseline. We show both in Table 4 with the two metrics reported across phenotypes, number of unlabeled examples, and lambda selection criteria. The differences in AUC and the average improvement were computed across all training set sizes.

Table 4. Difference in AUC and average improvement of semi-supervised learning over the supervised baseline.

Discussion

Incorporating unlabeled data into the model using basic EM algorithm shows very promising results, as evidenced by Figure 1 (top left). For Crohn’s Disease dataset (Figure 2, top left), the fully supervised model trained on 10 labeled examples is only 74% accurate. With 3000 unlabeled examples added, the model receives a large performance boost: the accuracy is now 85%. It takes more than 300 more labeled examples for the supervised model to achieve the same level of performance. Clearly semi-supervised learning has a great potential, offering a large reduction in the amount of manual annotation that is required to train an accurate model.

Why does EM algorithm work? The top ten features (Table 3, left) learned by the supervised model are simply too general to reliably identify a Crohn’s Disease patient: notice the “Pain” and “Prednisone” features (“Prednisone” is a drug used to treat many inflammatory diseases). On the other hand, adding unlabeled data (Table 3, right) leads to a feature set that is much more specific to Crohn’s Disease: “Pain” no longer appears on the list; Humira, Cimzia, Natalizumab, Certolizumab pegol, and Pentasa are all medications that are used to treat this condition. With few labeled examples, there is apparently not enough signal to capture the high number of drug names. However, by adding data that cluster with the positive labeled examples, the drug name features are found to be highly discriminative. Thus, unlabeled data helps to obtain better model parameter estimates.

However, the behavior of the remaining three phenotypes in Figure 2 paints a more complex picture. To remind the reader, Figure 2 presents the performance of the models where labeled and unlabeled instances are both given the same weight. While injecting a small amount of unlabeled data (500 unlabeled examples) improves the model performance, adding a larger amount (1000 and 3000 examples) is detrimental to classification accuracy for two out of four datasets we tried (Ulcerative Colitis and Multiple Sclerosis). This effect of unlabeled data is likely caused by violated model assumptions. When a large number of unlabeled examples is present, model parameter estimation is strongly influenced by the counts from the unlabeled data. The model essentially performs unsupervised clustering, using the labeled examples mostly to assign cluster memberships. When the most probable two-class clustering of the data does not match the annotated class boundaries, the unlabeled data can skew parameter estimation, potentially even leading to worse estimates than with labeled data only.
Introducing the $\lambda$ parameter that downweights the unlabeled data leads to more accurate model parameter estimation. As we decrease $\lambda$, injecting additional unlabeled examples should more thoroughly describe the space we are classifying in without swamping the highly valuable gold standard instances. This results in more consistent improvements over the supervised baseline. Observe that basic EM (Figure 1, top left) did not seem to take full advantage of unlabeled data: increasing the amount of unlabeled data from 500 to 3000 resulted in a reduction in accuracy. By lowering the value of $\lambda$ (Figure 1, bottom row), EM makes increasingly better use of unlabeled data, pushing the 3000 curve higher. At $\lambda = 0.05$ (Figure 1, bottom left; Figure 3) as the amount of unlabeled data is increased to 3000 examples, the semi-supervised models beat the supervised baseline for most training set sizes.

Applying our lambda selection heuristic results in a similar behavior (Figure 1, top center; Figure 4), although the overall gains over the supervised baseline are smaller both in terms of the AUC (2.49 vs. 4.14 for $\lambda = 0.05$) and the average improvement in accuracy (0.70 vs. 1.14 percent average improvement).

Using 10-fold cross-validation for lambda selection (Figure 1, top right; Figure 5) brings about overall gains that are comparable to using a small lambda, both in terms of AUC and the average improvement in accuracy. However, cross-validation does not appear to consistently pick the best lambda. For example, for the Crohn’s Disease dataset, it is possible for the semi-supervised models to do better if $\lambda = 1.00$ is selected for all amounts of unlabeled data we evaluated, in terms of both AUC and average accuracy improvements. For Multiple Sclerosis (see Table 4), cross-validation does not seem to take full advantage of the unlabeled data: the model that has access to 500 unlabeled examples outperforms the models that have access to more unlabeled data. At the same time for $\lambda = 0.05$ the best result is achieved by the model that has 3000 unlabeled examples; that model also outperforms all models selected via cross-validation in terms of both AUC (6.74) and average accuracy improvement (1.92). Surprisingly, even the simple lambda selection heuristic makes better use of unlabeled data than cross-validation: the models that utilize the heuristic, outperform the models where lambda was selected through cross-validation when 1000 and 3000 unlabeled examples are included.

Overall, whether lambda is computed using our simple heuristic, using 10-fold cross-validation, or simply set to some small value, the unlabeled data has the strongest positive effect on model performance when the amount of labeled data is relatively small. For $\lambda = 0.05$ (Figure 1, bottom left) the best semi-supervised model reaches its top performance at around 150 labeled examples. It takes more than twice as many labeled examples for the supervised model to reach the same level of performance. Eventually, as the number of labeled examples in the training set grows, the models are capable of finding good parameter estimates from the labeled data alone and the learning curves for the supervised and semi-supervised cases become very similar.

These findings are relevant to scaling up phenotype algorithm development for projects such as eMERGE, PGRN, and now BD2K. Domain expert time is always limited, and if a maximum performance can be achieved by

![Figure 4. Learning curves for $\lambda$ set by heuristic.](image1)

![Figure 5. Learning curves for $\lambda$ set by cross-validation.](image2)
combining a small seed of label instances (100-200) with unlabeled data, that would lead to gains in efficiency. If the domain expert time is plentiful, then large amounts of labeled data would be preferable as the completely supervised model will reach accurate parameter estimates.

**Conclusion**

Even though for some datasets the basic version of EM did not succeed in beating the supervised baseline for larger amounts of unlabeled data, it appears to be possible to overcome this shortcoming. Introducing the lambda parameter that downweights the unlabeled data leads to more consistent gains over the supervised baseline. Clearly, semi-supervised learning can be of high importance in practice. Are there any practical lessons we can learn from the experiments we presented?

To answer this question, let us first identify two properties of a model that makes use of unlabeled data that a practitioner of semi-supervised learning would find desirable. First, a semi-supervised model should not perform worse than the corresponding supervised baseline. Clearly, if adding unlabeled data is as likely to lead to performance deterioration as to improvement, it is too risky to use in practice. Second, the semi-supervised model should make a full use of unlabeled data that is available to it. Out of two models, we prefer the one that can “squeeze” more out of unlabeled data, resulting in larger gains over the supervised baseline.

In light of these properties, we can draw several lessons from our experiments. It appears that semi-supervised learning of the type we discussed in this work has a higher chance of success if augmented EM is used. A priori, the most obvious approach to setting its lambda parameter would be to use n-fold cross-validation. Empirically, simply setting lambda conservatively (i.e. to some small value) works a little better, possibly due to the sensitivity of semi-supervised learning to the amount of labeled data (n-fold cross-validation has to allocate some portion of the labeled data as a validation set for parameter evaluation). The simple lambda selection heuristic we introduced also has some desirable properties over n-fold cross-validation: it often results in more consistent improvements over the supervised baseline and for larger training set sizes it results in performance level that is no worse than the supervised baseline. At the same time, it is much more efficient, which may be important for rapid development of multiple phenotyping models. Finally, the heuristic does not require the implicit supervision of a human-generated list of acceptable weights as in cross-validation. If the size of the unlabeled data were increased by an order of magnitude, the cross-validation procedure may require manual adjustments to its inputs to find a suitable value.

For future work, we are planning to examine the behavior of semi-supervised learning under the scenario where an order of magnitude more unlabeled data is available to the models. We will also investigate the use of Bayesian inference methods for model parameter estimation such as Gibbs sampling.

Abstract

Identifying inpatients with encephalopathy is important. The disorder is prevalent, often missed, and puts patients at risk. We describe POETenceph, natural language processing pipeline, which ranks clinical notes on the extent to which they indicate the patient had encephalopathy. We use a realist ontology of the entities and relationships indicative of encephalopathy in clinical notes. POETenceph includes a passage rank algorithm, which takes identified disorders; matches them to the ontology; calculates the diffuseness, centrality, and length of the matched entry; adds the scores; and returns the ranked documents. We evaluate it against a corpus of clinical documents annotated for evidence of delirium. Higher POETenceph are associated with increasing numbers of reviewer annotations. Detailed examination found that 65% of the bottom scoring documents contained little or no evidence and 70% of the top contained good evidence. POETenceph can effectively rank clinical documents for their evidence of encephalopathy as characterized by delirium.

Introduction

POETenceph detects encephalopathy in inpatient notes from all clinical and ancillary domains. Encephalopathy is a broad term for brain disease, damage or malfunction\textsuperscript{1}. It is characterized by an altered mental state. Delirium is a sudden encephalopathy or state of confusion, which is associated with hyperactivity, somnolence or both. It is characterized by an acutely altered mental state, also referred to as an acute change in mental status (ACMS). We will be using delirium as the encephalopathy of interest and ACMS as a synonym for delirium.

Encephalopathy Identification

Identifying patients with encephalopathy that manifests, as delirium is important because it is prevalent, often missed\textsuperscript{2-4}, and the longer it persists the greater the risk to the patient. Importantly, some delirium is treatable. Practice guidelines for preventing and dealing with delirium have been created\textsuperscript{5,7}.

Patients who experience delirium have longer hospital stays, more ICU days, and frequently are on mechanical ventilation longer than non-delirium patients.\textsuperscript{6,8-11} They are also more likely to require post-hospital institutionalization. Studies show that patients with persistent delirium have a 2 to 4-fold higher chance of dying within the next year.\textsuperscript{8,9,12} All of this extra care is expensive. Delirium has been estimated to cost the U.S. healthcare system between $38 billion and $152 billion annually.\textsuperscript{7,13}

Delirium is estimated as being missed in the majority of older, delirious patients.\textsuperscript{2,3,14} These misses may be due to unfamiliarity with psychiatric conditions and their treatments and the prevalence of the hypoactive forms. Wancata et al. found that non-psychiatrists’ diagnostic sensitivity in detecting general psychiatric disorders ranged from 31.3-89.5\%\textsuperscript{15}. Delirium is particularly difficult because its symptoms fluctuate throughout the day. To correctly diagnose it, a clinician must look at the time course of mental status changes, the history of predisposing illness, any medications taken, any alcohol or other substance withdrawal, and pertinent environmental changes.\textsuperscript{16} It is probable that age and vision impairment are correlated with a missed diagnosis because physicians are over-looking symptoms they believe are explained by a known condition (age-related decline and perception problems, respectively).

This tendency, over-looking symptoms due to erroneous ascription, points to the need for clinical decision support. Automatically identifying documents with evidence of encephalopathy written about patients with no pertinent diagnostic codes is important to the hospital as well as the clinician and patient. Encephalopathy increases the complexity of patient care, which should be reflected in hospital reimbursement and case mix statistics.

Automated Evidence Identification
The automated identification of clinical evidence has the potential to improve clinical decision support for delirium. In cases where a physician has recognized delirium symptoms, but has wrongly ascribed them, it will be important for clinical decision support systems to identify those symptoms in order to re-direct the thinking of the clinical team. In all but a very few electronic health record systems (EHRs), the description of symptoms are found in free-text notes. ICD-9 codes and other structured text reflect current and “working” diagnoses assigned to inpatients, but symptom extraction requires natural language processing (NLP).

Our lab has developed an NLP pipeline\(^7\) to extract “disorder mentions.” Disorder mention is used in NLP to refer to all terms related to bodily malfunction. It includes signs and symptoms (sometimes grouped as clinical findings), diseases, diagnoses, and syndromes. In this paper, we will use the term “evidence” instead of disorder mention. Evidence seems a more accurate term when discussing EHR data that suggest a diagnosis because it does not imply, necessarily, that a decision has been made about what the data signify.

We have adapted the UtahPOET NLP pipeline to find evidence of encephalopathy (POETenceph) by including a realist ontology of encephalopathy.

**Ontologies**

Ontologies are used to incorporate world knowledge (e.g., semantic information) into NLP systems. An ontology includes the concepts, relationships, and rules governing their interactions.\(^8\) Most biomedical informaticists are familiar with the National Library of Medicine (NLM) Unified Medical Language System’s (UMLS) Metathesaurus and Semantic Network\(^9\), an amalgamated ontology of medical terms from multiple, diverse source vocabularies.

The UMLS Metathesaurus is not built using realist principles. Realist ontologies are designed to ensure that the concepts represented reflect real-world entities.\(^10\) The most important example of this principal from the current system is the distinction between an EHR entry and a disorder mention. If a clinician writes, “the patient has dementia and is unresponsive,” UMLS Metathesaurus mappings would be to the disorder mentions “dementia” (C0497327) and “unresponsive to stimuli” (C0857494). However, the terms “dementia” and “unresponsive” are ambiguous. Dementia could refer to Alzheimer’s disease (C002395) or any one of the other 581 related concepts in the UMLS Metathesaurus. Unresponsive could refer to “unresponsive to questioning” (C2188201) or any one of the other 35 related concepts. This term-use ambiguity is generally acknowledged. However, there is a second type of ambiguity that is conflated into the idea of a disorder mention, the clinician’s knowledge. If we assume that the sentence is linking unresponsiveness to dementia and that the clinician knows that “unresponsive to questioning” is a symptom of dementia, but “unresponsive to stimuli” is not, then we can assume the reference is to “unresponsive to questioning.” However, if our second assumption is false and the reference is to “unresponsive to stimuli,” then we should alert the clinician to their mistake in ascribing the symptom to dementia.

Realist ontology development forces us to differentiate the two types of ambiguity because we must separate what is happening in the patient, from what the clinician is thinking, and what is written in the EHR. These three things are different types of real world entities. What is happening in the patient is a level 1 entity (a real thing), what the clinician is thinking is level 2 (a mental representation), and what is written in the record is level 3 (a written representation).\(^11\)

One alternative to including an ontology is to train machine learning classifiers to classify clinical records into diagnostic categories. This method has not been generalizable across datasets\(^12\) probably because evidence is expressed in many different ways and structure of the documents differs. Therefore training a generalizable classifier would require a tremendous amount of training data. There would also be no guarantee that the resulting classifier reflects accurate biomedical knowledge. Although it would reflect the consensus of the clinicians whose documents it was trained with, there is no guarantee this is accurate.

**Ontology and Evidence Rating**

The ontology can be used to find evidence and then rate it’s association with a diagnosis of encephalopathy in the form of delirium. To find evidence is a straightforward dictionary match including lexical variants. One common way to match lexical variants is to use the UMLS Metathesaurus. We employ this technique.

To rate the association between the matched ontology concept and the diagnosis of encephalopathy, is a process of determining the semantic similarity or relatedness between the matched concept and the diagnosis. Semantic similarity is based on the separation between concepts in the hierarchical structure, while relatedness can use relationships other than hierarchical. See Batet, et al.\(^13\) and Pedersen, et al.\(^14\) for discussions of different approaches
to calculating semantic similarity and relatedness. In broad terms, there are two groups of semantic relatedness algorithms, those based on an ontology and those calculated from corpus statistics.

Corpus statistics alone may not lead to good semantic similarity judgments because the use of language cannot be used to understanding the meaning of language. It is the problem that psychologists refer to as the “symbol grounding” problem. In essence, words in a system cannot derive meaning from other words because words are arbitrary symbols with no intrinsic meaning. Using a realist ontology, we ground our words by attaching them to entities in the world. The resultant ontology is then used to judge semantic relatedness.

To make this judgment, we combine a path-length metric from the ontology with information content (IC) measures following the example of Pedersen, et al. and others. We use a simple measure of centrality for path length to determine semantic relatedness, since we have a central point representing complete knowledge (a diagnosis of encephalopathy). For IC, we used the number of term matches with and without stemming found in the UMLS Metathesaurus. IC is generally done with corpus statistics, but we reason that uniqueness within the UMLS Metathesaurus is a better indicator of uniqueness within the field. The final IC indicator we use in term length. We reason that longer terms are only included if the information they impart is necessary.

Methods

Evaluation

To evaluate our approach, we will look at two system aspects. The first is POETenceph’s ability to recognize EHR entries as evidence of encephalopathy in the form of delirium. The second system aspect will be its ability to combine the evidence to rank clinical documents based on the likelihood the patient was experiencing delirium.

We will compare the POETenceph output to 100 de-identified clinical documents from the Pittsburgh dataset. The corpus was created by author YS. The full description of the corpus creation is in Shao, et al. The documents were identified as related to delirium using topic modeling. Two subject matter experts (former nurses including co-author CW) annotated the mentions related to delirium in each document. The annotation process is also described in Shao, et al. Annotation was covered under University of Utah IRB_00043685.

We show the overall results compared to each reviewer individually and to the annotations matched between reviewers as well as the unique annotations across reviewers. With a condition as difficult to define as delirium, we think that each expert’s contribution should be considered. Therefore, for the detailed look at the POETenceph results we classified the amount of evidence based on the number of unique annotations across the two reviewers. There was a tendency for reviewer 1 to annotate only a few concepts. Documents were categorized as showing little or no evidence (up to 3 annotations or delirium denied in the text), some evidence (delirium implied in the text), evidence against delirium (another condition stated in the text), and good evidence (5 or more annotations or delirium stated in the text).

Since POETenceph is being developed to augment a word-matching system that searches for the words “enceph” and “deliri,” with proximity negation, we will also look at the occurrences of those words in the annotated corpus.

UtahPOET pipeline

The UtahPOET pipeline (Figure 1) is described in detail in Doing-Harris, et al. It is built in Apache UIMA and has the common NLP pipeline structure. Pre-processing includes sentence splitting, tokenization, and part-of-speech tagging. We add a preprocessing step for POETenceph that identifies label-value pairs (e.g., “Ca 8.6”) using regular expressions (Figure 1, section F). The regular expressions match noun-number pairs.

UtahPOET is unique in that it separates well-formed sentence (i.e., prose) from ill-formed sentences (i.e., nonprose) so that nonprose sentences can be re-split and prose sentences can be dependency parsed to facilitate processing. Non-prose sentences are split at line breaks because their internal cohesion is not important. Prose sentences are dependency parsed to allow more appropriate mapping of concepts, whose constituent words are separated in the text and to attach attributes (negation, experiencer, uncertainty, generic) to the concepts. For example, “infection in her uterus” mapped to “infection of uterus.” Generic mentions are like “psychiatry” in the sentence “patient sent to psychiatry for evaluation.”

Multi-word terms and their attributes are found in nonprose by adjacency. We reason that nonprose sentences are telegraphic and unlikely to include long-distance dependencies. Long-distance dependencies can only be understood by recognizing clausal structure.
Figure 1. The UtahPOET pipeline. Zoom in for form detail.

Post-processing (Figure 1, section K) specific to the SemEval competition is not used here. However, the removal of terms erroneously matched to disorders is retained ("sinus", "tongue", "blood", "ear", "a.m.", "dr.", "md", "dr", "D. D.", "m", "pm", "he", "mr.", "CT", "P", "Ht", "Eyes", "DATE", "T"). We also add a post-processing step in which any disorder mention found in a label-value pair is ignored. Instead of the remainder of the post-processing, we search the text of the identified disorders against the Encephalopathy ontology to determine whether they are evidence of encephalopathy.

Ontology of Encephalopathy Characterized by Delirium (OECD)

The main points of interest in the OECD are the level 3 (written representation) EHR entry, the level 2 (mental representation) clinical entities (i.e., disease picture, clinical picture, clinical finding, and diagnosis).

The upper level of a realist ontology contains the entities continuant and occurrent. Continuant subsumes the entities dependent continuant with generically dependent continuant and specifically dependent continuant and independent continuant. Explaining these entities is beyond the scope of this paper.

Figure 2. A) Proposed entities for the Ontology of encephalopathy characterized by delirium are in the red box. All other entities are from the Information Artifact Ontology. B) Proposed clinical picture entities.

Figure 2 shows some of the IAO Information content entities we propose. The EHR entry entity is a textual entity from the Information Artifact Ontology (IAO), which is an information content entity, which is a generically dependent continuant. The clinical entities we propose all fall under the Ontology of General Medical Science.
entities disease picture, clinical picture, clinical finding, and diagnosis. These entities are data items, which are also information content entities. A diagnosis of encephalopathy is a diagnosis of mental disease from the Ontology of Mental Disease. A diagnosis of mental disease is an OGMS diagnosis. The clinical findings that we propose are either OGMS clinical history findings or OGMS physical examination findings. We use the diagnostic criteria described in across several journal articles to associate clinical findings, clinical pictures, disease pictures and diagnoses. We do not attempt to address any physical aspects of the patient, only the clinician’s interpretation of the patient.

We created the ontology in stages. The first stage used automated extraction of UMLS Metathesaurus concepts from sentences hand-culled from medical records because they related to Delirium. We reconciled these concepts against the diagnostic criteria for delirium as stage two. Stage three is putting the ontology into BFO format. Stage four will include an expansion of the ontology with terms identified by our ontology management system SEAM and the terms identified in this study. The final stage will be obtaining expert agreement on the final ontology.

POETenceph

We incorporate the OECD by creating two Apache Lucene indices. The first index contains the unique ontology identifiers and labels (i.e., ontology key) associated with each of the ontology entities. Centrality scores are calculated for each entity by starting with the diagnosis (encephalopathy) and associated disease pictures (encephalopathy and urinary tract infection), which are set to centrality of -1. As you travel out across relationships from the disease picture, each level adds 1 to the centrality. The scores are normalized with division by the longest path length. Example centrality, diffusion, and length scores are listed in Table 1.

Table 1. Example centrality, diffusion, and length scores for OECD entities.

We designed the second index to accommodate the variability in language used by clinicians and to measure diffusion. It was created by matching all of the terms in the ontology (EHR entry instances and entity labels) to the UMLS Metathesaurus. Matches were restricted to the clinical source vocabularies and disorder or medication semantic types. In this index each term was associated with the ontology key of the search term that returned it, and its measures of diffusion, centrality, and length (see Table 1 for examples). Diffusion was the number of matched terms returned. Once all the terms have been searched the maximum number of matches was used to normalize the diffusion of each term, keeping it between 0 and 1. The result is subtracted from 1 because less diffuse is better.

The final aspect of the term that we used to calculate its score was the length of the term again normalized by the length of the longest term. The final score is the mean of the centrality, diffusion, and length. We score the document with the sum of the scores for the evidence that is positively asserted (not negated), experienced by the patient, and not generic.

Results

The most important test of POETenceph is determining whether high rated and low rated documents are correctly categorized. In the first set of figures we show two ways of looking at the human annotations across the documents. Figure 3a shows the POETenceph scores as they compare to each reviewer individually. Figure 3b shows the POETenceph scores compared to the annotations matched across the reviewers and the unique annotations found when combining the responses of the two reviewers. In both images it can be seen that the trend of the POETenceph scores follow those of the reviewers. It is apparent that they follow reviewer 2 more closely than reviewer 1 and the unique annotations better than the matched annotations. We find this preference for reviewer 2, who also led the number of unique annotations, was due to her annotating a higher number of pieces of evidence. Visual inspection
indicated that her annotations were valid. In one instance (file #44), she annotated “Change in mental status,” “sluggish,” and “combative” that reviewer 1 did not.

![Figure 3](image1)

**Figure 3.** Comparison of scores from POETenceph and Reviewer results: A) Each reviewer separately. B) The annotations matched between the reviewers and the unique annotations across the two reviewers.

In a more detailed examination, we looked at the top 20 and bottom 20 documents for the amount of evidence highlighted by the human reviewers (see Figure 4). In the bottom 20, 13 showed little or no evidence of Encephalopathy or Delirium (65%) within this group 1 had controlled encephalopathy and 1 had controlled delirium. One document showed some evidence of delirium (5%), and 6 showed good evidence (30%). The 20 highest rated documents showed almost the same pattern 14 had good evidence for delirium (70%), 3 had evidence of another condition (15%), 1 had controlled delirium (5%) and 2 had little or no evidence (10%). Three high scoring documents had evidence for related conditions (depression, alcohol withdrawal, and kidney disease), but without delirium.

![Figure 3](image2)

**Figure 3.** Comparison of scores from POETenceph and Unique Annotations: A) the bottom 20 files. B) The top 20 files. ○ indicates the text states no delirium, ★ indicates that the text states delirium present.

Looking at the word search for “enceph” we find only 11 documents contained the string, 3 from the low scoring documents 3 showing little evidence and 1 showing some evidence. Four of the high scoring documents contained the string “enceph,” 3 had good evidence of delirium and 1 had some evidence.

Matching the string “deliri” we find more coverage. Sixty-four of the 100 documents contain the string. It is found in only 9 of the 20 lowest scoring documents and only 4 of those contain little or no evidence, 3 contain good evidence and 2 contain some evidence. Of the 20 highest scoring documents 17 contain the string “deliri.” Two of the mentions contain little or negated evidence, 2 contain other conditions with delirium stated as not being present. Two high scoring documents with good evidence for delirium did not contain the string.
We then compared the POETenceph annotations with the expert annotations. We again looked at 21 documents across a range of scores from low to high. We found two obvious problems because we built UtahPOET to identify disorder mentions, POETenceph does not find medication or instrument mentions. These entities exist in the ontology but comparison to the ontology is done after UtahPOET has run.

Looking only at the direct evidence for delirium, POETenceph consistently misses “mental status changes,” “unable to follow commands,” “unresponsive,” “agitated,” and “not communicate.” Mental status changes, unresponsive, and agitated are simply missed by UtahPOET. Unable, follow and communicate are identified as concepts by UtahPOET, but not as evidence by POETenceph. The other class of evidence that is missed is evidence that is not found in the UMLS Metathesaurus. For example, “screams alternating with drowsiness,” “minimally verbal,” or “not clear mentally” are not found there.

POETenceph identified 249 positively asserted pieces of evidence, 64 are agreed-upon by at least one reviewer (26%). Eighty-six (35%) annotations are problems from UtahPOET, including repeated erroneous mappings of “M],” “man,” “block,” “he” (12 times), and “ca” (16 times). The remaining 98 we think are related to encephalopathy, but missed by the reviewers either because their task was to locate direct evidence (39%). This task orientation may also explain why only 5 of the 30 useful negated pieces of evidence were agreed-upon by a reviewer. POETenceph erroneously negated five others. Twenty-five of the negated evidence findings were errors like those found in the positively asserted evidence and therefore not useful.

The annotators found 107 pieces of evidence missed by POETenceph. Twenty-one were medications or instrument mentions, 3 are not disorders (Psychiatry, ammonia, potassium), 47 were pure misses (e.g., “agitated,” “acute psychotic event,” and concepts including “mental status”) and 38 are not in the UMLS Metathesaurus.

**Discussion**

We found that the POETenceph performed the task of ranking documents based on the amount of evidence of encephalopathy in the form of delirium well. Higher scores indicated documents that contained more reviewer annotations. The scores tracked particularly well with reviewer 2 and the total number of unique annotations in a document. Seventy percent of the top 20 and bottom 20 scoring documents were appropriately placed. Only 15% of the documents in top group and 20% in the bottom were completely misplaced. These findings indicates that using a realist ontology combined with measures of centrality, diffusion and length, it is possible to calculate scores for evidence in a document that corresponds well with expert judgments.

By restricting our search to documents without diagnostic codes for encephalopathy, we will be able to identify evidence that should be brought to the attention of clinicians and medical coders. This evidence can be presented to clinicians to encourage them to re-evaluate the patient or the billing codes whichever is appropriate.

This performance is an improvement over string search. The string “enceph” only returns 11 of the documents two of which would be completely misplaced. The string “deliri” returns many more of the documents because it was used in the creation of this document corpus, but the documents are unranked so although only 6 contain little or no evidence there is no indication of which 6. Also 3 documents with good evidence would be missed.

This study alone does not prove the utility of realist ontologies. It does indicate that they are useful. Having an ontology for the construction of a diagnosis from clinical findings that is separate from the UMLS Metathesaurus allows us to exploit the Metathesaurus’ ability to represent term use. We can also change the diagnostic elements without advocating for changes to the Metathesaurus.

The most obvious problem exposed in this study is that UtahPOET is restricted to matching disorder mentions whereas clinical evidence also comes from medication and instrument mentions. There are other improvements to UtahPOET that would aid performance of POETenceph. We need to address the erroneous mapping of small strings like “he” and “M],” as well as the missed mappings of “agitated,” “mental status” concepts, and “depressive.” Our next step will be to address the problems with UtahPOET.

In another project we are working on formalizing the Encephalopathy ontology. This formalization will include fixes to the current associations between the entities as well as the extension into level 1 entities. The formalization process requires input from clinicians to determine the settled science linking level 1 entities, the state of the practice linking level 2 entities and the imprecision of clinician language when transcribing their thoughts and impressions into the EHR. We will be investigating the use of probabilities on the relation between EHR entries and mental representations. Once these extensions have been added to the ontology we will need to reexamine how we calculate centrality.
For concepts not found in the UMLS Metathesaurus from the SemEval challenge we developed a structure SVM component for UtahPOET. We did not have training data to train the component for the equivalent pieces of evidence nor did we try the component with its current training because it does not currently work well. In future work, we will upgrade the component and obtain more training data for it.

The final area of investigation that this study has spurred is the relationship between disorders and body locations. Currently we determine each of these concepts separately. However, there must be a method to use one as a sanity check against the other. It seems that if a body location is found it should be used to restrict the possible matches to its attached disorder. For example, and that some disorders carry a body location with them “angina pectoralis” is only in the chest. We may be able to extend this idea to the mapping of strings into the ontology.

In future work we will also investigate the balance of the three measures, which go into our scores. It is possible that the current balance gives terms length too much impact on the final score for its informational content. It may be better to weight centrality higher than length and possibly also diffusion.

Limitations

The test corpus had only documents that had been previously identified as relevant to delirium. Therefore, we may have our encephalopathy detection set too loose. Because we are in no danger of missing delirium mentions, we cannot be sure we would catch them all. Our next evaluation will contain a predetermine mixture of cases.

We are also limited in that we did not enforce agreement between the annotators. We do not believe that it is necessary for all expert reviewers to agree on each and every annotation. Individuals will always have a slightly different opinion on what constitutes important evidence for conditions as difficult to define as delirium. Forcing arbitrary agreement would create the illusion of a strict definition. We do think that having several reviewers would allow us to choose annotations favored by the majority. A majority opinion may be more indicative of the prevailing medical consensus. In future work, we will strive to have five reviewers for each file, although that will have implications for the number of files we will be able to have reviewed.

Conclusion

An effective document ranking system can be created by combining a disorder-identification NLP pipeline with a realist ontology. Comparing disorders to ontology entities and scoring the matches based on diffusion, centrality and the term length can assess the evidentiary value of disorder mentions.

Abstract

Despite the potential advantages, implementation of mobile devices and ongoing management pose challenges in the hospital environment. Our team implemented the PROSPECT (Promoting Respect and Ongoing Safety through Patient-centeredness, Engagement, Communication and Technology) project at Brigham and Women’s Hospital. The goal of PROSPECT is to transform the hospital environment by providing a suite of e-tools to facilitate teamwork among nurses, physicians, patients and to engage patients and care partners in their plan of care. In this paper, we describe the device-related decisions and challenges faced including device and accessory selection, integration, information and device security, infection control, user access, and ongoing operation and maintenance. We relate the strategies that we used for managing mobile devices and lessons learned based on our experiences.

Keywords: device management, communication, health information technology, patient engagement, nursing informatics.

Introduction

The use of technology to manage health and wellness is becoming commonplace. Adoption and use of web-based technologies in everyday life has exploded over the past decade1,2 and the majority (87%) of American adults use the internet1. Many internet users go online to get health information for themselves (72%), or for a family member or friend (50%)1. The use of mobile devices is also becoming widespread; 90% of Americans own a cell phone, over half (53%) a smart phone,3 and increasingly, many own tablet computers. Many Americans report that they use their mobile device as a tool for managing their health. A recent article indicates that there are approximately 90,000 mobile health apps to manage a range of health-related activities1.

Many consumers are using technology to manage health and wellness, and there is a growing recognition of the need for patient engagement in healthcare5. The Health Information Technology for Economic and Clinical Health (HITECH) Act meaningful use program (2009) requires that providers engage patients in their healthcare through the use of technology. A key goal of meaningful use is to make consumers full partners in their care by providing e-health tools that increase access to health information, support activation (e.g., active involvement in their treatment plan), and that help consumers to gain control over their health and wellbeing6,7. This has led to provider and healthcare organizations promoting the use of personal health records or patient portals in outpatient settings8,9. However, there are limited examples in the literature that describe strategies and e-health tools to provide patients with access to their health information in hospital or inpatient settings. Based on a systematic review of patient engagement
technologies in inpatient settings, Prey et. al. (2014) reported a dearth of published papers describing technologies to engage patients in inpatient settings. The research that has been done in this area is largely confined to pilot and usability studies. None of the papers included in the systematic review described in detail the operational issues related to implementing e-health tools and devices to engage patients, the infrastructure needed for everyday use, and the management issues associated with implementation of these tools in busy acute care settings by a multitude of patients. Early work by Berg et. al. (1999) argue that successful design and implementation of health information technology (IT) applications requires a socio-technical approach; e.g., insight into specific work practices and the dynamic interaction between users and technology in the context of their workflows

In 2014 our team from the Center for Patient Safety, Research, and Practice at Brigham and Women’s Hospital (BWH) implemented the PROSPECT (Promoting Respect and Ongoing Safety through Patient-centeredness, Engagement, Communication and Technology) project on BWH medical intensive care (MICU) and oncology units (http://www.partners.org/cird/PROSPECT/Index.htm). PROSPECT is funded by the Gordon and Betty Moore Foundation and BWH. The units (20 ICU beds, 40 oncology beds) were selected to participate based on the GBMF’s interest in targeting ICUs and the relatively large percentage of oncology patients that are transferred to the MICU. Our goal is to transform the acute care environment by providing a suite of e-tools to facilitate teamwork among nurses, physicians, patients and to engage patients and their care partners in their plan of care. We hypothesize that through this partnership, we can eliminate preventable harms, make health care more affordable, ensure that patients and families make informed choices about their health care, and improve communication and concordance on goals of care. One component of the PROSPECT project is a Patient-centered Toolkit (PCTK). The PCTK is a web portal that is designed to provide patients and their care partners with the core set of information needed to engage in their plan of care during an acute hospitalization. In addition, patients can use the PCTK to message their care team and to provide feedback on their plan of care.

As part of the PROSPECT project, we partnered with our medical librarian to research strategies for ongoing operation and maintenance of bedside devices used by patients in hospital settings and found no peer reviewed literature on this topic. After implementing mobile tablets at each bedside for BWH MICU and oncology patients, we have learned some important lessons. In this paper, we focus on strategies for implementing and managing mobile devices in hospitals and lessons learned based on our experiences from the PROSPECT project. Key questions related to bedside device implementation and management are included in Table 1.

Table 1: Key Questions Related to Bedside Device Implementation and Management for the PROSPECT Project
Methods

We used a socio-technical systems approach\textsuperscript{14} to develop the PCTK\textsuperscript{12}, to identify device requirements, and to identify strategies for ongoing device management. In the 10 months prior to PCTK implementation, we used a range of strategies to gain insight into the MICU and oncology units’ work practices into which we would implement the PCTK. We conducted workflow observations, interviews, and focus groups of care team members, patients, and care partners. Based on our evolving set of requirements and the concerns expressed by clinicians and patients, we scheduled meetings with hospital, health information management (HIM), and infection control leadership to address the key questions that arose (Figure 1). In addition, we met regularly with information systems (IS) leadership to negotiate integration with existing BWH and Partners HealthCare (PHS) IT systems and to secure approval for device integration and management plans. The details of the iterative, user-centered PCTK development approach are described elsewhere\textsuperscript{10-13}. Here we focus on the on the socio-technical aspects of identifying device requirements, the procedures needed for managing bedside mobile devices for the PROSPECT project, and our experiences to date.

Results

Using the socio-technical systems approach, we identified challenges in terms of device and accessory selection, user access, integration, information and device security, infection control, and ongoing operation and maintenance in the hospital environment. In the sections below we describe the requirements and the implications related to implementing mobile devices at the bedside for patient use.

1. Device type, accessories, storage and user access

Based on initial feedback from patients and clinicians, we had originally planned to install touch screen, interactive, “smart” devices with built-in keyboards on a moveable arm at the bedside. These devices would support patient access to the PCTK and could be stored flat against the wall when not in use. However, we were unable to implement this approach due to space constraints in the room and the organizational decision to implement a non-touch screen device for use by clinicians in each patient room (device would not be accessible to patients). Therefore we made a decision to use mobile tablet devices. One implication of this decision was that our programmers were developing the PCTK software for use on a Linux, Windows\textregistered operating system and a selection of a device that ran on a different operating system, such as Android or iOS, had development implications.

Once the decision was made to use mobile devices, several issues required consideration including mobile device selection, whether to provide a keyboard, and identification of a device storage strategy that would promote patient and care partner access throughout the hospitalization and ensure the device could be easily charged. We initially identified the following bedside device requirements based on the PCTK technical requirements and user feedback: light weight, optimized screen size, multi-touch screen capability, Bluetooth low energy, and virtual keypad functionality. We explored multiple mobile devices and notebooks and rated each including the iPad Air, iPad mini, Nexus 7 and 10, Surface Pro, ATIC PC Smart, Xperia Series, the Galaxy Note 10.1, Arrows Tab, Macbook Air, LaVie Series, and the CF-LX3. After consideration of infection control (notebook keyboards were difficult to clean) and storage requirements (see below) we made the decision to go with a mobile tablet, rather than a notebook. The Apple iPad Air was the best fit as it met technical and end user requirements, required minimal instruction for use, and received positive feedback for usability from end users. In addition, PHS was using iPads
with patients in other projects and our development team had experience programming on the iOS platform. We purchased 50 iPad Air 2, Wi-fi, 16 GB devices (Apple, Cupertino, CA) for use by patients (and/or designated caregivers) on PROSPECT units to access the PCTK. The total cost for the devices (including the warrantee) was $37,900 ($758 x 50 devices).

We also decided to enclose all devices in a case. Key requirements for device cases were ease of decontamination between patients (no crevices) and preventing damage if the device was dropped. The case needed to be easily gripped, durable, waterproof, and lightweight. We reviewed two different cases including the Trent Airbender 1.0 and the military grade Griffin Survivor Case. The Trent Airbender included a keyboard but it was unclear how the keyboard could be cleaned between patients. We selected the Griffin survivor case which was commercial grade and met all of our requirements. The total cost for the cases was $3999.50 ($79.99 x 50 cases). A small percentage of patients we interviewed stated that they needed a tangible keyboard for use with the iPad so we decided to provide accessory keyboards upon request. The keyboards we chose were flexible bluetooth/wireless waterproof keyboards. To date, we have not received any requests for the accessory keyboard. The total cost for the keyboards was $23.98 ($11.99 x 2 keyboards).

The main requirement for device storage and user access was that patients have easy access to the PCTK at all times. This meant that each room would have its own device and charger that are treated as part of the room’s equipment and be within reach of the patient from hospital bed. While iPad stands and wall brackets were considered, they were not selected. iPad stands raised concerns about patient falls and wall brackets were ruled out because they did not enable the patients and care partners to use the iPad from anywhere in the room (e.g., the bed, a chair, or couch). Based on bedside workflow observations on inpatient Oncology and MICU units different device housing was developed for each environment. The rooms in the MICU were smaller and had more equipment than the rooms on the Oncology units. Both environments had over-bed tables but the tables did not have the capacity or potential to hold a mobile device in a practical and sustainable way. We looked at other existing equipment in the rooms and found that in Oncology there were bedside nightstands. Plastic bins (see Figure 1a) were purchased and installed on each side of the bedside table to facilitate access from the bed or the chair.
unit director, baskets were emptied and the devices and chargers were placed in the baskets upon initial installation (see Figure 1b). Over time, the baskets were filled back up with supplies in addition to the devices. Meanwhile, our second and long-term solution, recommended by the clinical staff, was to use IV poles with baskets on them which could be placed near the bed but easily wheeled to the side if the space was needed for bedside care (see Figure 1c). We installed the poles in each of the rooms and placed the devices in the baskets. Over a few weeks, the poles were either pushed out of the rooms by clinicians, or, they were used for intravenous therapy and not for housing the devices. The clinicians stated that they did not like the extra equipment in the room. Therefore, they have reverted back to using the baskets on the wall to hold the devices. While not ideal, this solution was acceptable because the patients in the MICU are often times incapacitated and it is more common that the Health Care Proxy/care partners use the PCTK. Therefore access from the bed is not always needed.

2. Device integration strategy and device security

We worked with our development team and PHS IS department to identify a device integration strategy that met the needs of the PROSPECT project and was consistent with PHS security policies. First, patients and care partners needed to access personal health information and communicate about their plan of care with the care team; therefore, all devices were connected to the PHS secure wireless network. Second, PHS policy required passwords to be centrally managed and information on devices to be cleared after each patient use. We used an enterprise mobile device management (MDM) solution (AirWatch® by VMware®, Atlanta, GA) to monitor the 50 mobile devices used by approximately 1000 patients/care partners. The MDM software provided remote security controls and reporting capabilities that met both PHS information security policies and HIPAA regulations. Specifically, the MDM software ensured that the iPads were assigned to users, compliance policies were managed, and device tracking was done from a central console. Thus, any device could be quickly locked down and secured when necessary.

*Table 2: PROSPECT Project device and WiFi issues July 2014-February 2015 (N= 50 iPads; 305 patients/care partners)*

We also used content management software, Kiosk Pro Lite (Kiosk Group, Inc., Frederick, Maryland) to restrict access on the iPad to the PCTK only. The iPads were configured by the MDM application to only allow access to the Kiosk Pro Lite software. This prevented data from being downloaded on mobile devices, in compliance with PHS information security policies. All personal health information and patient-provider messaging functionality on
the PCTK were available via secure web services. Therefore, we eliminated the need to clear data on devices between each patient use (although with the AirWatch software, we did have this capability).

Prior to implementation, we were concerned about device theft. We mitigated this threat not only by restricting user access to the PCTK, but also by configuring the MDM software to disallow internet access on all devices outside the PHS firewall. Therefore, the iPads were rendered useless if stolen. We communicated this to patients and clinical staff via signs and weatherproof/laminated, high-tack, white, vinyl labels on the back of the iPad case (see Figure 2). These labels were also applied to each of the chargers and cords. Thus far, our approach has been successful. Since go-live in July of 2014, only one device has been reported as missing.

![Figure 2: iPad Security Label](image)

We identified issues related to devices and WiFi connectivity after implementation of the PROSPECT project (see Table 2). Locking down the iPad devices in kiosk mode did have unintended consequences in that we were unable to leverage the full interactive capabilities of the iPad. First, all pop-ups were suppressed; we were unable to use iframes for some external links or third party apps. This limited the content that we could display. Second, we were unable to use the iPad’s notification functionality to display alerts on the lock screen (e.g., when receiving a message from the provider). Finally, patients and care partners could not use the iPads for personal web-browsing, entertainment, email, or video.

Because PROSPECT is a research project, we needed an enrollment strategy that met IRB requirements, PHS information security policies and HIPAA regulations. The IRB required informed consent from all patients and care partners. Patients who had capacity could provide permission for one or more care partners to access their personal health information via the PCTK. For patients without capacity, the healthcare proxy could be enrolled and could use the PCTK on the patient’s behalf. First, the process involved securing informed written consent from the patient or health care proxy using the 8-page consent form approved by the IRB. We adopted portal access best practices where possible including providing unique user names and passwords for each user and following a defined permission process. We leveraged existing BWH/PHS policies and practices related to enrollment in the PHS enterprise outpatient portal, Patient Gateway. Once consented, patients/health care proxy completed a PHS access authorization form. An additional form was completed by the patient and care partner for each care partner that the patient identified. Next, we used the PHS administrative portal to enroll patients and care partners. Specifically, users were assigned unique user names (an existing email address) and passwords (assigned by administrative portal and changed by user at the time of the first login).

3. Infection control procedures

During interviews before implementing the PROSPECT project, both patients and clinicians expressed concerns regarding device cleaning procedures. We met with hospital infection control specialists to establish a systematic process for disinfecting devices between patients. To decrease the risk of contamination associated with devices...
being carried in and out of rooms, we assigned one device to each patient room. We communicated the policy that all devices stay in the rooms at all times to hospital staff, patients and care partners. We also posted signs in the patient rooms reminding patients and care partners that the devices were for use in the patient room only. We worked with the BWH environmental services team to implement the approved process for cleaning both iPads and device holders after each patient use along with the other standard equipment in the patient room (see Figure 3).

Figure 3: Process for Disinfecting iPad Holders Between Patients

Step 1: Don gloves.
Step 2: Remove iPad from plastic holder.
Step 3: Wipe all of the exposed surfaces of the plastic device holder (outside and inside) using standard disinfectant wipes in use on BWH patient care units. The surface must be wet for the designated time listed for the disinfectant wipe.
Step 4: Check for any leftover stains and repeat as necessary.

Process for Disinfecting iPads between Patients

Step 1: Don gloves.
Step 2: Unplug all connectors from the device and remove any visible stains using standard disinfectant wipes in use on BWH patient care units.
Step 3: Wipe front of iPad using the standard disinfectant wipes in use on BWH patient care units starting at the top corner moving left to right from the top of the device to the bottom of the device. The process of cleaning the front of the device should take no less than 10 seconds. The surface must be wet for the designated time listed for the disinfectant wipe.
Step 4: Wipe top of frame and proceed by rotating the iPad in 90 degree steps until all sides of the frame have been cleaned.
Step 5: Turn the device and wipe the back surface starting at the top corner moving left to right from the top of the device to the bottom of the device. The process of cleaning the back of the device should take no less than 10 seconds. The surface must be wet for the designated time listed for the disinfectant wipe.
Step 6: Check for any leftover stains and repeat as necessary.

Discussion

Despite the advantages, the process of implementing and managing mobile devices in the hospital setting poses multiple challenges. Using a socio-technical approach, we identified a host of issues related to accessory selection, user access, integration, information and device security, infection control, ongoing operation and maintenance. Overall, the socio-technical approach has been useful for identifying and addressing device-related issues and concerns with stakeholders as part of the project planning process. The mobile devices (iPads) have been available on our MICU and Oncology units for over eight months; thus far, the experience has been positive. Enrolled patients and care partners have used the PCTK via hospital-issued iPads to communicate with the care team, contribute to their plan of care, and access their personal health information. To date, we have experienced minimal technical issues with the devices. While we were concerned about device theft prior to implementation, theft of the iPads has not been a problem. Interestingly, missing chargers has been the most common problem, one that we have not solved. Despite our efforts to include stickers on the chargers that indicate that they are BWH property, we have replaced 30 chargers so far (at $19.00 for adaptor and $29.99 for 6ft cord equates to $1,469.70 or an additional $200
per month in charger replacement costs). We are currently working on a secured solution for managing the device chargers.

We learned throughout the project that device-related decisions can have unintended consequences. As noted, we made the decision to use mobile devices after we learned that we could not install interactive, “smart” devices on a moveable arm at the patients’ bedside. This decision required some rework by our software developers to optimize the PCTK for use on the iOS operating system. Additionally, we had to address mobile device storage, charging, infection control, and security issues within our original timeline. Using a socio-technical approach, we worked through these issues with stakeholders and arrived at solutions in parallel with the PCTK software development. Some of the solutions were more successful than others. For example, establishing a device storage protocol so that devices were accessible by patients, continuously charged, and not in the “way” of clinical staff was difficult. We found that there was not a single best way to meet these requirements across units and we implemented two different solutions, one more successful (oncology units) than the other (MICU).

Our decision to lock iPads into kiosk mode facilitated information and device security, but it also led to an unexpected loss of access to MedlinePlus content. Initially, we linked to MedlinePlus educational content for test results, medications, and problems. We chose MedlinePlus because the content was at a consumer level of health literacy, had broad content coverage, and did not have advertisements. MedlinePlus contained licensed content from other sources and their license agreements did not permit framing of their content from their site. Medline Plus started blocking the framing of educational content in December 2014, several months into our project and our patients lost access to all of the educational content (e.g., all of the infobuttons “broke”). We quickly changed to other content sources and we started the process of implementing the web service version of MedlinePlus Connect so that we can once again use that content.

Our information security requirements have been a challenge at times. PHS requires encryption of all mobile devices that display patient health information including a lock screen and passcode. The lock screen appears when the battery power is less than 20% or if the device is restarted (e.g., the battery completely dies and the device is then plugged in). Even though the devices are in kiosk mode, a separate passcode is required to bypass the lock screen. When the lock screen appears, it can only be unlocked with the assistance of our research staff.

Cost represents a barrier to widespread adoption of mobile devices. In addition to the hardware and software costs, the administrative infrastructure needed to keep track of the devices and to enroll patients is significant. For the PROSPECT project, devices were managed by the research team. Sustainability outside the context of a research project will require an organizational approach to systematically address the issues identified by our team. Building this infrastructure would require institutional commitment and resources. One lower cost strategy that would mitigate access, device security, infection control, and operational concerns is to allow patients and care partners to access the PCTK on their own mobile device. A “bring your own device (BYOD)” strategy has much appeal as hospitals are essentially liberated from concerns related to removing prior data and configuring access to device after each patient use, monitoring and tracking devices to prevent theft, cleaning devices per hospital infection control protocols, and maintaining devices and accessories (e.g., losing chargers). A BYOD strategy should improve accessibility from the locked screen as patients and care partners would not have to remember additional passwords. To ensure privacy and security of patient health information, a BYOD strategy would require access via web-based patient portal applications with standard username and password authentication requirements. The use of native apps downloaded onto the mobile device to access web-based patient portal applications should enhance interactivity (i.e., by leveraging device specific API’s such as push notifications), as long as patient data resides on secure, HIPAA-compliant servers. Ideally, patients and care partners would download an app onto their mobile device at their convenience (e.g., as part of the hospital admission process). Additionally, such a strategy may increase flexibility for access by care partners who are unable to be at a patient’s bedside. Finally, with a BYOD strategy providers could “prescribe” mHealth apps that serve to engage patients in understanding and managing their care during recovery and after leaving the hospital16. However, this requires a rigorous mHealth app certification and
approval process to be in place. Next steps for the PROSPECT project include developing a BYOD strategy that will improve patient access to the PCTK on all BWH inpatients units.

There are several limitations associated with this project. We implemented the devices at a single hospital and within the context of a research study. It is not known how generalizable our experience is to other hospitals or healthcare settings. In addition, we have been using research assistants to enroll patients and track the devices. More research is needed to evaluate how these device-related functions could be integrated into a hospital environment without this level of support.

To our knowledge, this is the first report of lessons learned related to implementing mobile devices at the bedside for an extended period of time. We hope that with this paper, we have started the conversation and that others will publish their experiences so that barriers to implementation of e-health tools will be identified and addressed and these tools can be used more widely to engage hospitalized patients.

Acknowledgements

The authors would like to thank the BWH patients, family members, nurses, and physicians who provide ongoing feedback to inform our mobile device strategy. The BWH PROSPECT Project is part of the Libretto Consortium supported by the Gordon and Betty Moore Foundation.

Introduction

The US healthcare system is highly fragmented and fraught with attendant inefficiencies in delivery. Lack of interoperability and care coordination have resulted in duplication of care, increased error rates, adverse drug-drug interactions, reduced safety, and increased costs. It has been argued that investments in health information technologies will radically transform the healthcare sector by increasing efficiencies, decreasing expenditures and increasing quality. Prevalence of chronic diseases, and the need for improved quality of care and patient outcomes necessitates the application of Health Information Technology (HIT) and Health Information Exchange (HIE) to streamline patient care, eliminate waste, and improve care coordination, with the goal of ultimately improving patient health outcomes. This study aims at exploring the effects of HIT/HIE on the outcomes and quality of care for diabetes, asthma, acute myocardial infarction, congestive heart failure, and hip and knee fracture. We look at average length of stay, adverse drug events and 30 day readmissions as measures of quality of care. This study addresses the policy implications and areas for further research to increase the success of HIT implementation, success of HIEs and ultimately improve health care outcomes and reduce health care expenditures through improved care coordination across disparate provider entities, and readily accessible patient data across fragmented networks.

Methods

This study uses the Health Information Management Systems Society (HIMSS) IT database, coupled with the American Hospital Association (AHA) Hospital survey data and the Centers for Medicare and Medicaid (CMS), outpatient and skilled nursing facility Medicare claims data from 2006-2012, along with the standard Medicare file of patient claims for 2006-2012 as the control cohort. Using hierarchical clustering analysis methods, we construct HIT scores for measures of HIT and HIE implementation and penetration across 32 measures of HIT adoption. CMS, AHA and HIMSS data, is combined using the common Medicare Provider Number. The scores are then used as the coefficient of interest using fixed effects methods and multinomial regressions, controlling for hospital and patient characteristics, as well as time-invariant factors.

Results

This study finds that those institutions with the highest HIT scores for specific measures of clinical decision support, continuity of care documentation and clinical discharge and summary care documentation showed modest and statistically significant levels of improvement in health care quality outcomes for the 3 key outcome metrics of over the study period. Overall, more intensive use of HIT/HIE in the long run could help providers achieve better quality outcomes.

Discussion

This study has major implications for the future of HIT/HIE in coordinating care across disparate entities. Federal government initiatives aimed at improving care coordination, fostering health ecosystems, and reducing costs associated with unnecessary readmissions and length of stay and adverse drug events stand to benefit from this research in that it highlights tangible areas where HIT/HIE participation may be beneficial to achieving improved health outcomes and reduction of cost.
A Flexible Simulation Architecture for Pandemic Influenza Simulation

Abstract

Simulation is an important resource for studying the dynamics of pandemic influenza and predicting the potential impact of interventions. However, there are several challenges for the design of such simulator architectures. Specifically, it is difficult to develop simulators that combine flexibility with run-time performance. This tradeoff is problematic in the pandemic-response setting because it makes it challenging to extend and adapt simulators for ongoing situations where rapid results are indispensable.

Simulation architectures based on aspect-oriented programming can model specific concerns of the simulator and allow developers to rapidly extend the simulator in new ways without sacrificing run-time performance. It is possible to use such aspects in conjunction with separate simulation models, which define community, disease, and intervention properties. The implication of this research for pandemic response is that aspects can add a novel layer of flexibility to simulation environments, which enables modelers to extend the simulator run-time component to new requirements that go beyond the original modeling framework.

Introduction

Computer-based simulation is an important resource for analyzing the dissemination of novel infectious disease agents before empirical data are available [1]. Such simulations can provide valuable information about the relative impact of different potential interventions measures and estimate the relative susceptibility in different types of communities [2]. A major challenge for simulation architectures to be used in these settings is to provide sufficient turn-around time for simulation runs. In addition to the run-time performance per se, the simulation architectures must provide sufficient flexibility to allow for changes to both the simulation model and to the simulation performance engine. As in many other types of software systems, there is a tradeoff between run-time performance and modeling flexibility. Hard-coded and hand-tuned simulator implementations can take advantage of available hardware, such as multi-core processors, and can achieve acceptable or even respectable performance. It is a significant challenge to combine performance and flexibility to attain a well-balanced simulation system that can support interactive modeling, scenario development, and simulation result analysis for research and decision-support tasks.

Previously, we have studied stimulation architectures that take advantage of ontology-based models for disease, community, and intervention aspects [3]. In this approach, we use an ontology to model and specify different simulation scenarios and a translator to produce an XML-based specification for the simulation engine. This approach supports flexible modeling and allows scenario developers to use ontology editors such as Protégé [4] to define different parts of the simulation model and to reuse model components by using ontologies as a library of scenario building blocks.

Although this method provides flexibility and a systematic way of developing models, it is still limited to the expressibility of the ontology language and the subsequent translation process to the specification for the simulator engine. There are still qualities that cannot be modeled easily using this approach. For example, it is not possible to extend the capabilities of the simulation engine and introduce new features, such as intervention types and new types of data collection from the simulation process.

The aim of this study is to introduce an architectural approach to provide an additional layer of flexibility to simulations of influenza pandemics while maintaining run-time performance. Aspect-oriented programming [5,6] offers new ways of developing simulation architectures that alleviates design compromises originating from the tradeoff between run-time performance and modeling flexibility. This architectural approach allows us to add new features to the simulator without explicitly changing the core functionality and potentially degrading performance by
introducing more overhead (e.g., overhead from extension programming interfaces). Another advantage of this approach is that it is possible to use aspects in different combinations to achieve alternative configurations of the simulator. This technique makes it possible to build different versions of the simulator for specific tasks, such as additional logging, output in new formats, and new types of interventions.

**Background**

Aspect-oriented programming (AOP) is a programming paradigm that builds on object-oriented programming to provide mechanisms for modeling crosscutting concerns at the source-code level throughout the program. Here, crosscutting concerns are widespread functionality that cannot easily be modeled in a specific part of the program (e.g., as an object). Examples of crosscutting concerns are logging, consistency checks, and error handling. There are several programming languages for AOP, for example AspectJ [5] and AspectC++ [6]. These languages extend the existing programming languages Java and C/C++, respectively, with language elements for AOP rather than providing completely new languages. In AspectC++, programmers write aspect definitions in special source-code header files, which the AspectC++ compiler ac++ then transforms, or weaves, intro C++ source code suitable for compilation to executables using standard C++ compilers, such as GNU g++ and Microsoft VisualC++.

There are different modes for the weaving process. Aspect J has some additional features in that it supports weaving of compiled code (Java byte code), and allows for load-time weaving, which means that the run-time system weaves classes as they are loaded into the Java virtual machine. This type of flexibility is not available in AspectC++, because it is restricted to source-code weaving only. However, for run-time performance, there are clear advantages of source-code weaving. For example, source-code weaving (1) enables the compiler to perform optimizations on the complete (weaved) code, (2) allows aspects to introduce source-level constructs (potentially compiler directives and #pragma statements), and (3) facilitates manual inspection of weaved code if required.

One of the advantages of AOP is that it is possible to weave the program with different aspects to achieve radically different behavior from the program depending on the aspect configuration. For example, without any aspects a simulator could perform a basis simulation of an outbreak. However, with additional aspects weaved into the simulator code the program could collect additional information and statistics about the simulated outbreak, such as the gender and age distributions of infected persons. By combining different aspects, it is possible to achieve different program configurations and to develop special-purpose versions of simulators for specific tasks, such as experiments setups. In AspectC++, this type of configuration means that the program is weaved and compiled with a set of enabled aspects to form a new executable for each configuration.

**Methods**

The starting point for this work was an outbreak-simulator architecture developed in C++ [3]. As an initial step, we refactored the simulator source code to improve its structure and added unit tests (using CppUnit) to confirm proper functionality from the start. Next, we added testing aspects to ensure correct behavior from weaved code when running simulations. We then proceeded to evaluating the aspect-oriented architecture by implementing aspects for additional functionality, such as saving results directly to databases, checking consistency and supporting interventions.

**Results**

*Fundamental simulation architecture*

The fundamental simulation architecture is based on a simulator part that takes as input an XML-based specification of the simulation parameters and produces an XML file with the results [3]. In addition to the simulator, the architecture takes advantage of a scenario ontology that contains models of the community, disease, and basic interventions. Scenario developers use the ontology editor Protégé [4] to develop the scenario by instantiating concepts in the ontology. A Protégé extension transforms this ontology to the XML-based specification for the simulator core.
Figure 1 shows an overview of the architecture. The simulator consists of a simulator core algorithm with supporting modules for parsing specifications, applying interventions, logging, preparing result output, and so on. The architecture is based on object-oriented programming, which models essential modules and data components as C++ objects for efficient computations. From a user perspective, analysts can use the simulator architecture to prepare scenarios in the ontology editor, run them in the simulator, analyze the results, and, if required, revise the scenarios.

![Diagram](image-url)

Figure 1. Overall simulation architecture. The simulator takes as input a scenario ontology consisting of community, disease, and intervention models. The scenario ontology contains the necessary simulation parameters. The simulator consists of several modules with specific functions. The output of a simulation run is a compressed XML document, which contains a trace of the simulation with daily outbreak reports suitable for further analysis and visualization. End users (e.g., public-health analysts) parameterize the simulator using the ontology and control the simulator through a command-line interface.

The main advantage to using ontologies for specification of scenarios and simulation parameters is that it allows for (1) modeling flexibility supported by the expressivity of the ontology and the high-level editing tool and (2) reuse of model components across scenarios where the ontology acts as a scenario-component library. Although such ontology-based specifications work well, there are sometimes scenario properties that cannot be modeled easily using ontologies. These situations require additional flexibility. For example, the scenario developer may want to add concepts to the ontology that currently have no mapping to the XML-based parameters that simulator uses as input. Furthermore, the simulator implementation may not support these concepts at all. There is a need for a modeling middle ground where developers can add functionality to the simulator without actually interfering with the simulator code and modifying it manually (which is sometimes difficult and time-consuming to do and potentially error prone).

Aspect-oriented simulation architecture

Based on the fundamental simulation architecture, we have developed a new model for aspect-oriented simulation architectures. By taking advantage of aspects it is possible to develop simulators that are flexible in the sense that the basic simulation system can remain small and relatively unchanged while developers can add new aspects independently to change the simulator behavior significantly. Furthermore, it is possible to use the aspects in different configurations to effectively create diverse versions of the simulator architecture. As simulation
requirements evolve and usage patterns change, developers can define additional aspects and add them to the architecture.

Figure 2 shows the simulator architecture populated with aspects. In this architectural approach, the aspects add to the existing simulator code by modifying the behavior of the simulator modules at specific points and by possibly extending the data model by introduction of new member field and functions to existing classes. It is possible to define aspects that address crosscutting concerns by extending modules such as the user interface, parameter parser, data model, and output with additional functionality. For example, the developer may want to extend the simulator with functionality for taking advantage of new data sources (e.g., new types of community-related data) by enhancing the parser and other data-input modules in combination with introducing new properties to the data model.

![Simulator architecture with aspects](image)

**Figure 2.** Simulator architecture with aspects. Aspects weaved into the original simulator use pointcut expressions to add advice to simulator modules to extend their functionality. In this configuration, the aspects extend the simulator with functions for new interventions, output formats, logging, consistency checks, and so on.

**Potential simulator-architecture growth points**

Growth points are areas where it is especially interesting to extend existing systems. Developers of APIs often preplan software extensions, sometimes tacitly, by identifying areas where other developers may want to add functionality to a system. For instance, an API may support the growth point of adding import filters for new data and media formats (i.e., by providing appropriate calls and hooks). In outbreak simulators, it possible to identify candidate growth points where it is especially interesting to introduce extensions beyond what is possible to express using simulation parameters and configuration files. Note that both modeling interests (e.g., refined disease and community models) and implementation requirements (e.g., internal consistency checking and logging) can motivate such simulator growth points. Let us discuss potential simulator-architecture growth points that are possible to approach using aspects.

1. **Data sources.** New types of data as well as old data in new formats can become available to the simulator. It is possible to use aspects to develop import filters and data converter that parse and translate the input data to the internal data model. For example, aspects can add advice to an input XML parser to enable it to recognize new tags for new data elements.

2. **Data models.** The underlying data model for the simulation (e.g., classes for persons, mixing groups and other domain-specific resources) may be insufficient for certain types of scenarios. For example, public-
health professionals may want to introduce socio-economic factors in the simulation, which requires new properties in the data model. Aspects can use introductions to add to existing class definitions for central simulator concepts, such as persons and mixing groups.

3. Intervention modeling. Although it is possible to model basic interventions in the scenario ontology, there are complex interventions and combinations of interventions that cannot readily be modeled in this way. The simulator architecture can benefit from having an additional, advanced, way of modeling interventions. If needed, aspects can implement interventions using program code, which maximizes the flexibility in intervention modeling.

4. Tracing, logging, and run-time statistics. Simulators must produce sufficient records of the simulation runs, especially for lengthy jobs running for days or weeks. Developers can use aspects to implement and extend various maintenance and recordkeeping functionalities of the simulator. In AspectC++, for example pointcut expressions are useful for pattern matching of function calls for tracing and logging.

5. Consistency checks and unit tests. To ensure correct simulator operation, developers often add data-consistency checks and unit tests. It is possible to use aspects for implementing and applying such test as well as supplementing existing ones.

6. Result output. Analysts will rarely examine the raw simulation output directly. Normally, the simulation results will be stored and used as input to others tools, such as plotting and statistics packages. It is possible to use aspects to implement support for new output formats (e.g., suitable for efficient storage and processing) and to output additional data of interest from the simulation run, such as daily reports of the age of infected people.

7. Problem scalability. New scenario definitions can increase demand on the simulator, for instance in terms of community population and data granularity, which require increased memory and processing capabilities. Aspects can improve scalability by (1) changing data models (i.e., memory requirements) and (2) adding pragma statements, for example Open Multi-Processing (OpenMP) pragma directives for taking advantage of multicore processor architectures.

These growth points exemplify concerns that are fundamental to the simulator and, therefore, difficult to model as simulation parameters and in simulator configuration files. Aspects can contribute to simulator architectures by supporting such growth without developing full-grown API for each of them (which may add overhead and be difficult to implement because of their fundamental nature).

**Architecture Evaluation**

Let us consider two sample aspects as a basic evaluation of the architecture model. The aim of the first aspect is to change the output of the simulator. Figure 3 shows a sample aspect that adds an additional output format, HDF5, for the simulator results. HDF5 is a binary file format for storing large amounts of numerical data, such as measurements and other types of scientific data. This aspect adds a before advice to the simulation method to create and open the HDF5 file (by calling the H5Fcreate function in the HDF5 API) and an after advice to close the HDF5 file after finishing the simulation (by calling the H5Fclose function). Furthermore, the aspect adds an after advice to write the dataset to the HDF5 file (by calling the H5LTmake_dataset function) after the simulator has produced an array that summarizes the number of active infections for each day. The aspect defined in Figure 3 illustrates that it is possible to extend simulator functionality with a fairly compact aspect to achieve useful functionality. Moreover, it is possible to do so without requiring a formal extension API, which may unavailable or at least time-consuming to implement especially for specific situations.
Another application area for aspects in simulation architectures is implementation of interventions. Because of the variation of possible interventions, it is difficult to model many of them as simple statement or expression (e.g., an object with properties and logical expression). Potential interventions range from different types of social-distancing measures, such as avoiding physical contacts, canceling events, and closing locations, to immunization programs. Furthermore, the interventions can be applied at different times, according to different criteria, and in various combinations. Also, intervention compliance may vary. Therefore, simulation architectures require mechanisms for defining intervention models that are both simple and sufficiently expressive without actually making extensive modifications to the simulator source code.

The aim of the second aspect used for evaluation is to explore intervention modeling. Figure 4 illustrates how it is possible to implement interventions in the simulation architecture. This aspect adds functionality for closing and reopening schools in a community at different times in the simulation. The principal idea is to implement school closure by modifying the behavior of the simulator in such a way that school children do not get infected at schools. This task is accomplished by capturing the call to the method calculating the probability of people not getting infected and returning 1.0 if the mixing group is marked as closed. To control the closure and reopening of school mixing groups, the aspect adds a check before the call to the method responsible for stepping the simulation one day. This advice marks all school mixing groups as closed if the current simulation time is equal to the specified day of closure. Likewise, the advice marks all mixing groups as open once the current simulation time reaches the day of reopening. Furthermore, the aspect introduces a slice, which adds a closed property (data member), to the to the class representing mixing groups (Group). In addition, this slice enhances the class with member functions for closing, opening, and checking the closure status of the mixing group.

```java
aspect AspectHDF5 {
    hid_t file_id;

    // Create and open HDF5 file
    advice call("% Job::RunOutbreakSimulation(...)") : before() {
        std::string dbPath = tjp->target()->basePath + "_out.h5";
        file_id = H5Fcreate (dbPath.c_str(), H5F_ACC_TRUNC, H5P_DEFAULT, H5P_DEFAULT);
    }

    // Add data set for the number of infected people for each day to HDF5 file
    advice call("% Job::ReportOutbreakResultsSummary(...)") && args(summary, days) : after(unsigned int** summary, int days) {
        hsize_t dims[2] = {tjp->target()->iterationUpperBound -
                          tjp->target()->iterationLowerBound + 1, days};
        H5LTmake_dataset(file_id,"/summary", 2, dims, H5T_NATIVE_INT, *summary);
    }

    // Close HDF5 file
    advice call("% Job::RunOutbreakSimulation(...)") : after() {
        H5Fclose (file_id);
    }
}
```

**Figure 3.** Sample aspect for simulation output in HDF5 format. This aspect definition contains three advice statements for (1) creating and opening the HDF5 output file, (2) saving a summary array with the data about the number of active infections for each day, and (3) closing the HDF5 output after the simulation has completed.
To illustrate the effect of using the school-closure aspect, let us examine the effect of applying the intervention in different configurations. Figure 5 shows the results from running the simulator with the aspect in different modes and rerunning the simulations ten times for each case. The baseline case is a simulation of an outbreak in a community without any intervention (Figure 5a). The intervention aspect was then configured to close all schools on day 10 of the outbreak and reopen them on day 20 (Figure 5b) and, finally, to close on day 20 and reopen on day 30 (Figure 5c). The outbreak curves show the distinct differences in the result profiles of the configurations. Note that this experiment is an evaluation of the intervention modeled by an aspect rather than a simulation aimed at exploring

```c++
aspect AspectSchoolClosure {
    const int close = 10, open = 20;

    slice class SL {
        bool closed;
        void Close() { closed = true; }
        void Open() { closed = false; }
        bool IsClosed() { return closed; }
    };

    advice "Group": slice SL; // Introduce slice to the class Group

    advice construction("Group") && that(g) : after(Group& g) {
        g.closed = false;
    }

    // If the mixing group is closed, set the probability of people NOT getting infected to 1.0
    advice call("double Group::ProbabilityOfEscape(...)" && args(p) : around(Person const& p) {
        Group& g = *tjp->target();
        if (g.IsClosed()) {
            *tjp->result() = 1.0;
        } else tjp->proceed();
    });

    // Check if open or close conditions are met on each day in the simulation
    advice call("% Job::StepOutbreak(...)") && args(t, iter, iteration) :
        before(unsigned int t, unsigned int iter, unsigned int iteration) {
            JobSpecification &JS = tjp->target()->JS;
            if (t == close) {
                // Close all schools
                for (GroupListIterator giter = JS.Groups().begin(); giter != JS.Groups().end(); giter++) {
                    Group& g = **giter;
                    if (g.IsSchool()) g.Close();
                }
            } else if (t == open) {
                // Reopen all schools
                for (GroupListIterator giter = JS.Groups().begin(); giter != JS.Groups().end(); giter++)
                    (*giter)->Open();
            }
        }
};
```

Figure 4. Sample aspect for intervention modeling. This aspect implements school closure and reopening by (1) using introduction to add the closed boolean property to the Group mixing-group class, (2) effectively closing mixing groups by setting the probability of not getting infected to 1.0 if the closed property is true, and (3) setting the closed property to true on the day of closure and false on the day of reopening.
public health policies (which would have required additional scenarios, background data, repeated simulation runs, and result analysis).

Figure 5. Results from outbreak simulation using the school-closure intervention aspect. Each simulation is repeated ten times and the resulting curves show the number of active infections over time. (a) No intervention. Schools are open as usual. (b) All schools close on day 10 of the outbreak and reopen on day 20. (c) All schools close on day 20 of the outbreak and reopen on day 30.

Architectural model and development approach

Ultimately, aim of this work is a generalized architectural model that directs the implementation of flexible simulators. Figure 6 shows the conceptual model for the aspect-oriented simulation architecture. The guiding architectural principle is that there should be a core simulation system and data model with basic capabilities, and that aspects should add functionality in different configurations. Normally, the core simulation system is implemented as a conventional object-oriented program whereas the adjacent aspects are implemented in a corresponding aspect-oriented language (e.g., AspectC++ in the case of C++ and AspectJ in the case of Java). Using this approach, developers can implement the simulation architecture by establishing the core functionality and then add aspects around the core incrementally during the development process. For preexisting simulator implementations, developers can use a refactoring approach where they identify the core simulator part and then gradually extract existing features from the simulator system and refactor them as aspects.

It is possible to prepare the core simulation system for aspects extensions. Although aspect-oriented programming does not require an API for making extensions, it is still useful to define areas for possible extensions by paying attention to the software design. For example, it is advantageous to employ a (class and function) naming convention that enables aspect pointcut expressions to pattern match on the names. Furthermore, it is useful to promote growth points by adding (perhaps dummy) function calls at specific locations of interest in the algorithm code to allow for aspects to add advice. For example, an algorithm for calculating probabilities of infections among individuals in a mixing group can call additional (and perhaps dummy) functions at different computational stages to permit aspects to add advice through pointcut expressions.

Figure 6. Conceptual model for simulator development. The core simulation system is a small but still independently-functional conventional program that can run basic simulations. Aspects add to this functionality in different configurations.

Discussion

Aspect orientation enables flexible simulator architectures that support scenario modeling beyond what is possible in simulation parameters and configuration files. The use of aspects to extend a core simulation system has the advantage of allowing developers to improve the architecture incrementally by adding aspects individually and independently. Furthermore, this type of architecture support extensions without predefined API mechanisms, which may add run-time performance overhead especially for lengthy simulation jobs. Thereby, aspect-oriented simulator architectures provide significant advantages to pandemic influenza modelers when compared to present static simulation frameworks [7,8].

Although aspect-oriented programming is a powerful technique, there are certain modeling drawbacks. In particular, aspect-oriented code is difficult to read and debug in the sense that is difficult to know exactly what code is executing at specific locations. This is because several aspects may change and add to the behavior of functions through advice code hidden from immediate view. Nevertheless, there are jointpoint visualization tools that aid developers in reading aspect and advice code, for example the AspectC++ Development Tools (ACDT) and AspectJ Development Tools (AJDT) for the Eclipse development environment.

Developers constantly make different kinds of modeling decisions. In this type of architecture, one particular consideration is the choice between objects and aspects; that is, which modeling paradigm to follow. In some situations, it is possible to implement the same functionality as objects in the simulator core or, alternatively, as aspects added to the architecture. Our preferred guideline for such modeling decisions is to (1) use object-oriented programming for basic and common functionality, such as the simulator core, and (2) reserve aspects for extended and independent functionality while avoiding aspect interdependencies where aspects rely in the functionality of other aspects. In other words, we refrain from using aspects in the simulation core to promote simplicity and to avoid potential programming errors that could affect the simulation outcome.

An alternative to aspect-oriented programming is to use traditional object-oriented programming and define conventional APIs for extensions. This approach has the advantage of not bringing in the complexity of aspect-oriented programming and the weaving process. This method also forces simulator developers to identify growth points to support and implement well-defined interfaces among the architectural components. However, the disadvantage of this API approach is that it is less flexible than aspect-oriented programming and that it is difficult to achieve the same run-time performance as aspects because of the overhead associated with programming interfaces.
In aspect-oriented programming, it is possible to use introductions to extend the basic data model, as discussed previously. We have seen that aspect developers can extend the definition of a person (i.e., the C++ class representing persons in the simulation) with additional fields to represent properties such as age and primary-care provider. Doing so in programming interfaces is possible, but at the cost of additional classes and computational overhead. For example, object-oriented APIs often take advantage of polymorphism and virtual member functions (methods) to allow extension by addition of new subclasses. Unfortunately, the use of virtual function calls in tight simulation loops can be quite costly (because of the dynamic run-time lookup of virtual member functions). Aspects can avoid such costly look-up operations by weaving advice with regular member functions.

Conclusion

Simulation of influenza pandemics is important for response planning because of the possibility to predict outbreak dynamics and the relative benefit of interventions before empirical data are available. In general, there is a trade-off between flexibility in configuring simulators and run-time simulator performance. In this work, we have explored a novel simulator-architecture approach based on aspect-oriented programming. The results illustrates that it is possible to develop simulator environments based on a core system combined with extensions implemented by aspects. The aspect-oriented approach makes it possible to avoid the potential overhead of using programming interfaces and generalized system designs with complex mechanisms for extensions. In summary, we believe that this type of flexible and extendable architecture is an important step towards rapid modeling and simulation for pandemic preparedness and response.

Designing Asynchronous Communication Tools for Optimization of Patient-Clinician Coordination

Abstract
Asynchronous communication outside the clinical setting has both enriched and complicated patient-clinician interactions. Many patients can now interact with a patient portal 24 hours a day, asking questions of their clinicians via secure message, checking lab results, ordering medication refills, or making appointments. However, the mode of communication (asynchronous) and the nature of the interaction (lacking tone or body language) strip valuable information from each side of patient-clinician asynchronous communication. Using interviews with 34 individuals who actively manage a chronic illness of their own, or for a child or partner, we elicited narratives about patients’ experiences and expectations for using asynchronous communication to address medical issues with their clinicians. Based on these perspectives, we present opportunities for designing asynchronous communication tools to better facilitate understanding of and coordination around care activities between patients and clinicians.

Introduction
Asynchronous communication between patients or caregivers and members of their care team (physicians, nurses, and medical assistants, herein referred to as “clinicians”) has increased with the adoption of patient websites or portals. Patients may now interact with these electronic systems to manage basic health care needs, including filling prescriptions, receiving test results, being reminded of future screening and diagnostic testing, and sending secure communications to health-care providers. Some of these services are also now part of Federal policy. To receive full payment for seeing patients with Medicare and Medicaid coverage, Stage 2 Federal meaningful use criteria for electronic health records (EHRs) require healthcare providers to support patient use of secure electronic messaging and the ability to view, download and transmit portions of the electronic medical record. Several studies have shown the potential of these services to improve patient satisfaction and outcomes in patients with selected chronic conditions.

Despite the growing role of asynchronous communication between patients and healthcare providers via portals, patients have had limited involvement in their design and implementation. Asynchronous communication increasingly extends beyond secure electronic messaging and now includes reminders for preventive and chronic care tasks, notifications about medical test results, and patient uploads of survey and biometric data like home blood glucose and blood pressure readings. Outside of a few core features associated with high patient satisfaction, we understand little about what portal features can support the needs of patients for asynchronous communication and information, particularly for those living with chronic illnesses. Several underserved patient populations—including those from racial and ethnic minority backgrounds, and those with lower levels of education—are also less likely to use patient portals, raising concern that current portal design and implementations are not equitably accessible to those in need. Finally, asynchronous communication over portals is largely limited by what is provided by commercial EHRs and the possibilities of integrating with existing models of care.

To improve asynchronous communication over patient portals, we must consider the patient’s perspective of their use, effectiveness, and usability. The design of asynchronous communication should align with the Epstein et al. vision for patient-centered care, where care should “explore patients’ values and preferences; help patients and their families make clinical decisions; facilitate access to appropriate care; and enable patients to follow through with often difficult behavioral changes needed to maintain or improve health.” To this end, we elicit experiences from patients and caregivers in their use of patient portal asynchronous communication tools. To gather perspectives of patients who have ongoing health needs and are most likely to benefit from asynchronous communication, we recruited adult patients with diabetes and mothers of children with asthma. We oversampled racial and ethnic minorities and ensured an adequate sample of those with lower educational status to identify potential portal features that would engage these populations in asynchronous communication. Our study contributions are twofold: first, we present themes in patient experiences of asynchronous communication tools. Then, we suggest design implications
for asynchronous communication tools to better facilitate coordination of care between patients and clinicians between office visits.

**Background**

We frame our approach to eliciting patient experiences in using asynchronous communication tools as just one factor in chronic illness management and in the larger relationship with clinicians to support such management. Similarly, Abaidoo and Larweb situate information and communication technology in clinical practice as “[a] conduit for channeling health information to consumers” for two purposes: (1) making informed shared decisions, and (2) tailoring clinical interventions appropriately through timely communication. This definition conveys agency in decision-making to both patient and clinician, underlining the importance of understanding care activities and their priority in the patient-clinician relationship. Thus, communication facilitated by technology is one factor that can help a clinician and her patient negotiate goals, establish benchmarks of wellness, and manage health and/or chronic conditions. Patient access to medical information and communication tools is, accordingly, an important tenet of the Institute of Medicine’s recommendations to “cross the quality chasm” in health care.

Fowles et al. found that 80% of patients—regardless of health status, education, and income—had at least some interest in viewing the information in their medical record; respondents to the survey in this study were motivated by wanting to be more involved in their health care and by a desire to understand their medical conditions more thoroughly. Therefore, patients do desire to engage with their health information through tools such as patient portals. These tools have the potential to increase patients’ engagement in their own care, improve patient experience of care and, potentially, improve patient outcomes. A systematic review by Goldzweig et al. found that patients had generally positive attitudes towards secure messaging and access to the online medical record. The authors further found improved outcomes for certain chronic conditions when secure messaging and other functions of the portal were coupled with case management. However, the review also identified the importance of further evidence on the specifics of context and implementation in evaluations of portal functions. Much of the evidence of for patient benefit has come from implementations and studies in a limited number of settings.

Clinic-focused evaluations of asynchronous messaging systems assess clinician engagement, associated workload, and billing. In a meta-review of such evaluations, Wallwiener et al. found that physicians were slow to take up using secure messaging, but found benefits—such as less time spent on the phone and higher measured patient satisfaction—outweighed costs, particularly burdens on physicians’ clinic time (also supported by Kummervold and Johnsen). Goldzweig et al., however, found insufficient evidence that patient portals change costs or traditional forms of utilization. Tufano et al. highlighted the importance of aligning the organization and financing of care for providers to sustainably meet patients’ needs for access over secure messaging.

Benefits of asynchronous communication tools to both patients and patient-clinician relationships are multiple. Andreassen et al. found that benefits to patients included: “emancipation” of the patient-clinician relationship from the constraints of space and time during office visits; a valuable mechanism for “transferring responsibility” to the doctor for an issue once communicated; and a modality (writing) that helps patients to reflect and synthesize health information. Another benefit of asynchronous messaging cited by Sun et al. is the allowance for patients and doctors to communicate directly. As a result, the authors argue, “accuracy and authenticity” of patient messages was increased, a worthwhile tradeoff for the added time on the clinicians’ part spent addressing patient messages.

However, individual patient experience with asynchronous communication tools have principally been studied by quantifying engagement with and use of the system through patient message volume, and surveys of patients to examine use, expectations, and experience. Our qualitative study examines asynchronous communication tools as one aspect of all elements of care in managing chronic illness, a process that involves clinicians but takes place largely in the patients’ home and between office visits.

**Methods**

To inform our methods, we referred to recent workshop reports in the areas of human-computer interaction and medical informatics, which call for framing inquiry into patient-clinician communication from a patient-centered point of view. That is, we are interested in the patient experience of “asynchronous, remote” modes of communication in the context of the larger patient-clinician relationship. In shaping our interviews with patients and caregivers, we also emphasized “shared decision-making” between patients/caregivers and clinicians. In sum, we sought to answer:
How do individuals characterize their experiences of and expectations for using asynchronous communication strategies to coordinate health care with clinicians?

We recruited 34 participants from Group Health Cooperative, a large integrated healthcare delivery system in Washington State. All participants had a primary care provider in a Group Health owned and operated clinic. Participants included 16 mothers with children under 12 years of age who were diagnosed with asthma and being treated for asthma, and 18 adults diagnosed with Type 2 diabetes. Mothers of children with diabetes (mean age 38.3) were younger than patients with diabetes (mean age 73.0; also see Table 1). We oversampled racial and ethnic minorities (16 of 34 enrollees, the greatest proportion of whom were Black participants). Nine participants had a high school or lower educational level. We purposively sampled 26 (76%) of the overall interview sample to be current users of the patient portal. We defined portal use as having used one or more of the eight key services of the portal on two occasions separated by 30 days or more in the previous two years. These services included: viewing medical test results, visit summaries, immunization lists, allergy lists, medical condition lists; exchanging secure messaging with providers; ordering medication refills; and scheduling an in-person appointment.

In the case of diabetes patients with a close caregiver, the caregiver participated in the research interviews where possible and appropriate. These two cohorts were chosen because each is responsible for daily self-care related to the management of a chronic disease, each has frequent contact with health care providers and health care systems (e.g., scheduling appointments, filling prescriptions, scheduling lab tests, etc.), and all have regular opportunity and need to use communicate with their healthcare providers. Asthma cohort participants are denoted with A# identifiers and diabetes cohort participants have D# identifiers in the quotes highlighted in results.

We conducted 2 interviews each with all of the 34 individuals who were each managing a chronic condition of their own or for a young child. Interviews took place approximately six months apart, were conducted in the participants’ homes, and ranged in length from 30 minutes to 90 minutes. The semi-structured interviews inquired about patients’ health goals, priorities for completing health tasks, and examined patient-centered workflow in attaining health goals and completing related tasks. The research design was approved by institutional IRB, and researchers used a semi-structured script to guide the sessions in both interview instances. Interviews were audio recorded; after transcription, audio files were destroyed. We had approximately 1,300 pages of interview transcriptions as our dataset for this study.
Analysis
The group of researchers conducting interviews and those coding the transcripts overlapped; thus, as interviews were being conducted - particularly in the second round - researchers tracked themes emerging in real time (as described in the qualitative research approach by Strauss and Corbin\textsuperscript{24}). One author (JE) performed open coding on six pairs of interviews, using a list of potential themes identified during the interview period to seek patterns and name and define potential codes. Three other coders (LMV, LSL, KO) were trained with the codebook and tested its use on four pairs of interviews each. The four coders then met to revise and finalize the codebook for its use in pursuing themes to address the research question.

Given the variation in our populations of interest and their technology use, we were careful to inquire about multiple possible modalities of communication between patient and clinician (not only asynchronous), to obtain a full picture of the patient experience. Therefore, we were able to assess themes that emerged around the patient-clinician relationship, as well as patient motivations for utilizing their modalities of choice in coordinating with health care providers. We examine below two characterizations of patient experiences: themes that emerge in satisfactory patient-clinician asynchronous communication and those that coincide with unsatisfactory communication.

Results: Characteristics of satisfactory asynchronous communication
We grouped themes of asynchronous communication tool use that were consistent with positive or satisfactory patient experiences. Themes in satisfactory communication experiences included experiences where asynchronous communication enhances care, reduces patient uncertainty, and provides “health archives.”

Enhances care with follow-up
Participants contextualized their asynchronous messaging experiences in the relationship with their doctors. D07 described his doctor as someone who followed up diligently: “I had expressed a concern to her and she checked into it and wanted to know if I was still having a problem and she e-mailed me and I e-mailed her back.” Another participant used e-mail as a trusted communication medium because the doctor was skillful in judging when to follow up. “Some things require a response and others are just for their information, it depends.” (D03).

Participants felt that asynchronous communication was particularly beneficial when the communication complemented care received during a clinic visit, particularly when communicating between clinic visits also elevated the sense of patients’ responsibility for managing their conditions. For example, D09 expressed that “if you don’t answer [clinician e-mails], that would be inappropriate and certainly not taking care of yourself.”

The additional modality offered by asynchronous communication (i.e., writing) also assisted patients in following up more effectively. Participants who were satisfied with the asynchronous communication system tended to indicate comfort with expressing themselves in writing; this echoes previous research findings\textsuperscript{25,26}. D15 stated, “I can sit down and express myself more.” One participant in the diabetes cohort felt less pressure in office visits to cover all concerns, and felt more control over her health when able to follow up post-visit:

I’ve already left the doctor, I’m feeling a certain kind of way. I don’t know that my inadequate feeling is enough to make another appointment so it depends what it is that I’m feeling and then I can go ahead if I need to contact them, to do the email [secure messaging]. I’m just so pleased they got the email thing. (D03)

Asynchronous communication tools were also key to managing complex family arrangements, such as when non-custodial parents brought children to the doctor for a checkup. Asynchronous communication tools were used, in following up clinic care, to keep the custodial parent “in the loop.” In one case, a custodial parent used secure messaging to (1) tell the doctor ahead of time that the other parent would be accompanying the child, (2) send along health concerns in her absence, and (3) follow up with questions between custodial and non-custodial parents after the appointment. This participant, A09, explained: “It’s my control issue, this is what I need [the doctor] to cover, or could you just answer this for me or know this information when you talk [to the other parent].”

Reduces uncertainty in the plan of care
Participants also used e-mail to resolve uncertainty in the plan of care, such as questions that remained after an office visit. In some cases, the participants felt as though they needed less assistance from clinicians because they could access archived reports (such as after-visit summaries) and messages through the patient portal: “When I feel I need follow up I can check there, which is really nice that they have the online summaries.” (A16)
One participant with diabetes frequently used the patient portal’s secure messaging function to discuss his lab test results with clinicians. This not only reduced uncertainty, but increased his feeling of “buy-in” on engagement in his care. He felt his clinicians emphasized their responsibility to make sure the patient was adherent by using secure messaging frequently: “I don’t get by with ignoring anything,” he told us (D01). In another example, one patient on Warfarin had frequent contact with consulting nurses and indicated that the secure messaging was both informative and an indicator of the seriousness with which the participant should be managing his health: “I’m very happy that they follow up so diligently, because previously I didn’t think [the Warfarin monitoring] was that serious a thing, really” (D09).

Provision of automatic “health archives”
Participants also acknowledged that using asynchronous communication systems, such as secure messaging, had the advantage of automatically archiving their communication with clinicians, which they could review at a later date to inform their care management. Like many participants, A06 told us, “I don’t save paper notifications, but everything else is stored online.” The online archive of messages can also help patients understand their condition better. Caregivers also used the e-mail archives to access information as part of their responsibilities. One caregiver of a partner with diabetes (D10) told us, “Sometimes I check his [patient portal messages] because I know he doesn’t do it.” In this case, the archive of information facilitated social sharing of information that helps the patient manage his condition.

**Results: Characteristics of unsatisfactory communication**
The themes below were identified as characterizing unsatisfactory patient experiences with asynchronous communication tools on the portal, and included: failing to track issues in a coherent way, and exposing patients to inconsistent communication patterns.

**Fails to track issues**
Participants indicated that they had, in some cases, been “conditioned” by the system about expectations, such as response time on secure messages or lab test results. “I just go into [the patient portal] when I expect [lab results] should be done, and check it and see if it’s done” (D07). However, some of the conditioning by the system trained participants to believe that “no news is good news,” and if they never heard back from the doctor, the issue was not only no longer open, but in fact a non-issue. As one diabetes caregiver to participant D16 explained, “Unless there’s something really out of whack, and then [the doctor’s] office will call…[but my husband] is actually really well stabilized.” The uncertainty in these cases led participants to assume the burden was on clinicians to follow up as needed, but this is not ideal for optimum understanding of and coordination around illness management activities.

Participants also cited the inability to act on reminders to revisit an issue after a certain period of time. For example, a mother of a child with asthma is often advised to visit the child’s allergy specialist in 6-month intervals, but the mother is unable to schedule that far ahead on the patient portal system. Instead, she tries to call for an appointment immediately; if that tactic fails, she implements a reminder-to-remind system:

*If I go in for an appointment and the doctor says, ‘okay, we need to see [the children] back in six months,’ I’ll usually get home, I’ll call the next day, even though it’s six months out – sometimes their calendars don’t even, they’re not even that far out. But I call the next day because I might forget so well, I’ll just call and say, ‘okay, are you scheduling this far out?’* (A07)

A related problem was the lack of status indicators for unresolved issues, where communication tools on the patient portal were either “read” or “unread,” or had no useful status to keep participants informed of ongoing tasks associated with open issues. A15 wished for open medical orders and pending lab results to be flagged as open issues on the patient portal; she stated that such status information would give her “peace of mind.”

Secure messaging can be part of overall unsatisfactory communication leading to severed relationships between the patient or caregiver and clinicians. In one such episode, the mother of a child with asthma and a comorbid sleep disorder described a lack of follow-up from a provider on an expensive sleep study. “They did ask, do you prefer [a secure message] or [a] phone call? I said ‘either one,’ and we never received anything. And in turn, with that specialty...we have gone out of network.” (A04) Had the patient portal offered a way to track the status of issues associated with the sleep study, the clinician would have been notified that the issue remained open for the caregivers and patient.
Exposes Patients to Inconsistent Communication Patterns

Some participants were confused about how asynchronous communication tools in the patient portal worked within the larger health care information system. The patient portal, along with the multiple modalities of communication available to clinicians, formed a “black box” of a system where patients were not always certain what to expect. One patient never knew how she would hear about test results: “I think my mammogram, they never called me for that - they do send you a letter, so they aren’t consistent” (D01).

In a similar vein, another patient noted that although medical orders are being executed, there is no communication with the patient to ensure an order is completed: “They put [the lab test order] on the computer, but they don’t tell you to go in and have it done” (D13). Uncertainty in communication even affected the frequency of in-person office visits, confusing the patient and leading to potential lapses in illness management: “I haven’t seen [doctor] for six months. I don’t know when I’m going to see her again...Maybe I don’t need to, I don’t know.” (D13)

In the following section, we synthesize what we have learned about successful and unsuccessful patient experiences with asynchronous communication tools. We suggest design opportunities for such tools that could improve the patient experience, and increase patient-clinician understanding of care activities to manage chronic illness.

Discussion of Design Opportunities

Based on our findings, we have identified two major design opportunities for enhancing patient-clinician coordination when using asynchronous communication systems. First, incorporating patient preferences for communication modality in a transparent manner within the patient portal would facilitate a greater match between clinician efforts to remind and patient ability to receive and act on reminders. This is relevant to supporting Meaningful Use Stage 2 guidelines\(^2\), which include patient communication preference incorporation to improve patient access to information and online health content. Second, incorporating “status indicators” in the asynchronous communication system, giving both the patient and clinician the ability to indicate a range of statuses for individual care issues, such as “unresolved,” “under clinician review,” “awaiting clinician response,” and “resolved,” would give patients and clinicians a signaling system for prioritizing future tasks and indicating agreement on clinical tasks and issues.

To demonstrate that implementation of functions related to these design opportunities would improve patient-clinician and caregiver-clinician communication and coordination, we use the model proposed by Wilcox et al.\(^24\) to delineate benefits to care. Specifically, Wilcox et al. called for research to focus on three “communication goals” between patients and clinicians: (1) clinician awareness of patient symptoms, (2) patient awareness of care activities, and (3) shared decision-making. An overview of our design recommendations and their benefits according to this framework are presented in Table 2, and we further detail design recommendations in the following subsections.

Incorporating patient preferences

We found that preferences for different modalities varied within our sample cohorts, and preferences were highly individualized. This supports the requirement that providers begin to collect patient modality preferences (e.g., secure messaging, phone) as part of Meaningful Use Stage 2\(^2\), as the act of incorporating preferences seems to be a formidable opportunity to improve the patient-clinician communication loop. For example, some of the patients with diabetes strongly preferred messaging to using the phone, due to the low time pressure of writing messages and the assumed convenience to clinicians. “On the phone, the guy's got to be there and on the e-mail, once you send it, you send it and you know he's got the message” (D08).

However, some mothers of children with asthma preferred never to check their patient portal messages and many described their difficulty with remembering yet another password for an online account. Instead, mothers who spent a great deal of time traveling in the car, for example, preferred to see the clinic main number pop up on their smartphones, which acted as a reminder in and of itself:

Interviewer: It sounds like you don't get the calls from [all of your doctors] right now. Would you prefer texts over calls in general?
Participant: I really don't have an opinion. I mean if you can get the information out in a text, why not? But if not, then a call is fine too. At least I can see the missed number and recognize the number so I mean - you know what? Even saying that out loud, it sounds like I would prefer the visual, so yeah, I would prefer text. (A09)

These variations in modality preferences for non-urgent communications indicate that customizing modalities for asynchronous communication would offer a great benefit to clinicians (saving them time on communication issues) and to patients or caregivers (reducing uncertainty around how communication with clinicians would occur). In times of greater need, such as with an asthma exacerbation or worsening complications from diabetes, the benefit may be amplified further.

Table 2. Delineating benefits to design opportunities identified in the Wilcox et al.\textsuperscript{24} patient-centered communication framework

<table>

<td><strong>Patient</strong> more likely to follow up with open issues when communication uses preferred modality. <strong>Clinicians</strong> will have better information to act upon to help patients.</td>
</tr>
<tr>
<td>(2) Patient awareness of care activities</td>
<td><strong>Patient</strong> more likely to receive and act upon reminders for care activities through preferred modality. <strong>Clinicians</strong> will benefit from improved efficiency in reminding patients about care activities.</td>
</tr>
<tr>
<td>(3) Shared decision-making</td>
<td><strong>Patients</strong> and <strong>clinicians</strong> are more likely to connect efficiently over the patient’s preferred modality to make shared decisions.</td>
</tr>
</tbody>
</table>

The reduction of uncertainty to patient expectations would in turn increase the coherence of communication through the patient portal. Rather than the confusing “black box” mental model, patients would be able to expect a phone call or secure message – depending on their preferences – and the stress of awaiting information from clinicians could be reduced, particularly around test results:

“*They send you a letter telling you what your [lab test] results were, but it's not on [the patient portal]. Like it's totally separate, and they don't do it through e-mail, which is annoying because I don't like to call people and bug them.*” (D01)

This patient with diabetes did not know what to expect when awaiting test results; as with the “black box” problem before, the confidence in knowing what to expect can be troublesome for building trust in the patient-clinician relationship. Thus, we see an opportunity to let patients determine their preferences in a way that they can see in the system, such as a dashboard to view and update preferences about communication for various tasks, like receiving test results or receiving appointment reminders.

Finally, there are situations in which asynchronous communication simply may not work well. For example, one of our participants has been visually impaired since birth. This individual stated that she preferred phone calls with clinicians to any kind of asynchronous communication, such as secure messages or U.S. Mail (which required a software screen reader, or a paid human reading assistant, to convey this sensitive information). Although an edge
case in terms of context, we point to this individual’s experience to illustrate a case in which the utility and efficacy of notifications could be improved significantly by incorporating patient preferences:

Interviewer: Have you ever considered tools that might be helpful to [remember upcoming appointments]?
Participant: I’ve asked them to call me ahead of time to remind me, and they said they don’t send reminder calls.
Interviewer: That’s surprising to hear, actually. That was something you asked the front desk about?
Participant: Yes.
Interviewer: Did you ask your doctor directly about it as well?
Participant: I think I did, I don’t recall if I did or not. (D17)

The examples above are intended to highlight the frustrations patients experience when their preferences cannot be incorporated into patient-clinician communication. This is the first design opportunity we identified in our data analysis; the second design opportunity is that of using status indicators to signal open, in-process, and closed issues between the patient and clinician.

Indicating Status
Failures and frustrations with asynchronous communication between participants and clinicians largely stemmed from the participants’ uncertainty about the status of a given issue. It is often unclear to patients whether the lack of follow-up or response from a clinician indicates “no news is good news” or simply a lack of resolution. The most radical aspect of this design recommendation is, perhaps, giving patients the ability to change and control the status indication. Both the patient and clinician would be able to view and add information to open issues. However, the patient would indicate when an issue was resolved satisfactorily.

By empowering patients to send clear signals about whether an issue is open or closed, clinicians will be better able to understand a patient’s state of mind regarding medical concerns, and can prioritize issues that patients needed further assistance to close. For example, A15 brought up an instance where she did not hear back about sensitive lab test results over a long weekend. She stated she would have felt better to have just known from the clinician “we’re looking at your test results.” In this case, the participant would have benefited from a status indicator system that would have flagged the issue as unresolved, but in-process at the clinic level, to reduce her uncertainty regarding the open issue. Such feedback has been noted from parents managing children’s health care through patient portals in previous studies, where even a “read receipt” type feedback mechanism would have been a helpful system feature in the caregiver- or patient-clinician communication loop27. Additionally, previous studies have shown that patients managing a chronic illness are willing to engage with online health management, though clear communication “closed loops” between patients and clinicians would improve the patient experience28.

Often, participants wished for a way to notify clinicians that the issue remained open, despite the clinician having moved on. D08 shared an anecdote about attempting to get referred for foot care, but described an e-mail exchange with his primary care physician that was “never successful” (i.e., resolved) - and he continued to go without foot care or a reason for no referral.

Interviewer: How can [your doctor] be there for you? Tell me more, I want to get more insight there.

Caregiver: To share a lot more knowledge and let us know why decisions are made. We've asked him – ‘oh, I'll check on it,’ but we never heard back from him on it. Every time we go there, we ask the same question – ‘why was it denied, is there something you can do?’ It doesn't seem to be one of his top priorities. (D16)

In this case, the patient would benefit from being able to indicate that an issue was not satisfactorily closed, ensuring they receive all of the information needed to move on to other care issues and reducing damage to the patient-clinician relationship.

We suggest testing the addition of status indicators to issues opened by patients or clinicians, whether it arises during an office visit and subsequently requires follow-up (lab tests), treatment (new medications, therapies), or monitoring (ongoing lab tests, such as an A1c, or home measurement of peak flow meter). Open issues could be tracked, and the corresponding information and related tasks grouped, for the convenience of both the patient and the clinician; we recommend prototype testing to maximize the benefit of status indicators and to avoid alert fatigue among either patients or clinicians. This design feature could also indicate the state of the issue, such as if the next
task required input from the patient or clinician, clarifying expectations of both parties. Having a signaling system between the patient and clinician could both reduce uncertainty and impart shared, but clear, responsibilities to each party regarding resolution of the issue.

Status indicators could assist patients in following through with standing orders for regular labs, such as the A1c for patients with diabetes. In the current system, as D01 told us, “The A1c has been a little bit of a problem because my doctor has set it up so that I can go every three months, but if that time passes...they just discard it if you don't use it.” In a future system, with status indicators for open issues, this participant could log into the patient portal and see she had an open status item to complete: she could then visit the lab, so as not to waste the standing order. This feature would underscore the importance of teamwork between patients and clinicians, and conveys a sense of responsibility to the patient in managing symptoms or problems.

Limitations
The study findings are limited by the sample size, qualitative nature of the data, and inclusion of participants from a single health care system who all have access to the same communication systems and patient portal. However, the findings suggest opportunities for improving patient-provider communication and systems diverse health care settings.

Conclusion
As evidenced by our analysis, the patient experience in using asynchronous messaging tools could be improved to enhance coordination between patients and clinicians. Our sample included individuals from populations who have been less likely to engage in patient portals, those who avoided or reluctantly used technology, as well as avid smartphone users, to give a range of viewpoints on asynchronous communication tool use in the health care context. We found that the positive aspects of patient experience with asynchronous communication tools support the ability to supplement in-clinic communication. This support included: follow-up with care activities, reduction of patient uncertainty about care plans, and availability of “health archives” online. Negative aspects of using such tools, however, included lack of consistent patterns of use in patient communication and uncertainty about resolution to issues addressed through the tools. We present design opportunities to reduce the uncertainty that patients experience in managing chronic illnesses, while also strengthening roles and responsibilities between patients and clinicians in managing issues that arise in monitoring chronic conditions. We use our findings to provide practical, actionable changes to the design of asynchronous communication tools to improve the patient experience and facilitate the balance of work and responsibility in the patient-clinician relationship.

Abstract

The secondary use of electronic health records opens up new perspectives. They provide researchers with structured data and unstructured data, including free text reports. Many applications been developed to leverage knowledge from free-text reports, but manual review of documents is still a complex process.

We developed FASTVISU a web-based application to assist clinicians in reviewing documents. We used FASTVISU to review a set of 6340 documents from 741 patients suffering from the celiac disease.

A first automated selection pruned the original set to 847 documents from 276 patients’ records. The records were reviewed by two trained physicians to identify the presence of 15 auto-immune diseases. It took respectively two hours and two hours and a half to evaluate the entire corpus. Inter-annotator agreement was high (Cohen’s kappa at 0.89).

FASTVISU is a user-friendly modular solution to validate entities extracted by NLP methods from free-text documents stored in clinical data warehouses.

Introduction

The worldwide trend toward secondary use of health data for research opens up new and exciting perspectives for researchers in all the realms of medicine. The large adoption of EHRs provides a steady flow of data, structured and unstructured (and particularly free-text medical reports). Today, almost all the preeminent clinical research institutions have deployed Clinical Data Warehouses (CDW) 1–4, to store and integrate all the data produced in routine care.

Our institution, the European Hospital Georges Pompidou (HEGP) is a 730 beds public research hospital in Paris. An i2b2 CDW has been installed and used since 2008. It integrates data from more than 700,000 patients. 5 The large majority of the data stored is structured data with more than 100 million data points of lab results, but the data warehouse also integrates more the 4 million free-text reports in French ranging from discharge summaries, letters, to imaging and pathology reports.

Structured data, by their organized nature, are a target of choice for secondary use. However, free-texts are at least equally important. In medicine, free-text has always been the support of medical records. Free-text reports collect any information that the physician considers of any importance and that took a role in a medical decision. Text reports also include data that might be difficult to find elsewhere such as family history, results of exams performed outside of the institution, rejected hypotheses. Nevertheless, the extraction and reuse of data from free-text reports requires processing and dedicated tools and resources.

Structured and unstructured data capture different views on the patient and her/his disease. Billing codes, often coded with ICD-9 CM or ICD-10 capture the medico-economical aspect of a medical encounter. The main purpose is to evaluate the cost of the treatment provided; lab results coded in LOINC provide standardized biology lab results. Issues might occur when researchers attempt to leverage structured data in a context for which they were not designed. For example billing codes are not aiming at providing a global coverage of comorbidities of a patient. In their article, Li et al. 6 compared information found in structured data to information found in free medical text. They reported two types of differences: information completeness and concept granularity, and concluded that data extracted from free-text complement structured data.

Medical documents come in a large variety of type of texts. The biomedical literature reports text mining of radiology reports7–8 medical observations 9,10, nurse narratives 11 – documents produced for care activity – but also from documentations and guidelines 12. Most of these clinical documents are stored in CDWs. However they provide information of heterogeneous quality: for example a discharge summary is validated by a senior physician while observations or notes may be written by medical students.
Standardized text annotation is required to enable automated processing. Terms in the text are annotated using standard terminologies. The Unified Medical Language System® (UMLS®) is often used as a lingua franca for biomedical domains. Tools have been developed to assist annotators, such as the BRAT Rapid Annotation Tool 13 (BRAT is not dedicated to medical applications). However, manual annotation is a tedious and time consuming process that requires to follow guidelines, and therefore to be trained. The Natural Language Processing community has developed over the last decades many applications for virtually all the fields of medicine. For example, for the detection of incidental findings in chest x-ray 14, pneumonia or rheumatoid arthritis identification from narrative reports 15–17. There is a large variety of tools available for different purposes.

Medical concept recognizers (MER) leverage medical terminologies and linguistic resources to identify medical entities in free-text (popular MERs include MetaMap 18 developed by the National Library of Medicine, the Biportal Annotator developed by the National Center for Biomedical Ontologies – NCBO, or cTakes developed by the Apache Software Foundation). In addition to recognizing medical concepts, it is often needed to capture the context of the information. The meaning of concept can drastically change depending of the context (e.g. negation, potentiality, family history). Some of the previously cited tools include some context recognition. The most commonly used context recognizer is probably NegEx 19 for negation 20 and its extension CONText 21. Expert validation is often required to secure further use of the results. I2b2 itself proposes NLP tools through its ‘Natural Language Processing cell’ based on a HITEx 22 core. This functionality is encapsulated into i2b2 interface where the user can retrieve different types of concepts detected in text: diagnoses, discharge medications, smoking status.

Shivade & al. 20 reviewed 97 articles describing approaches to identifying patient phenotype cohorts using EHRs. Forty-six articles used NLP based approach.

A common task in a clinical research is the selection of eligible patients for a clinical study. It is a tedious and costly task that requires time and highly skills personal. In the case of retrospective studies, it is often required to browse through the entire record archive of a patient to identify relevant information. Tools have been developed to assist in the selection process. They provide a connection between CDW and NLP tools, and help the user in the selection process. Many systems use selection systems inspired by the “basket” from online-shopping websites 23, i.e. the clinician browse through available documents and identify those of interest.

However, it is often needed to be, not only able to identify patients that fit a set of criteria and are eligible for a study, but also to identify and annotated the presence, or the status of phenotypes in their record. We did not find a publicly available solution that would allow a flexible entity selection, and allow phenotypic annotation by one or more users.

Moreover, most of the documents available for research in our hospital are in French. Non-English languages lack tools and terminology, and despite substantial effort toward better NLP coverage simple solution are still needed. We needed a solution with good performance, reducing physician time involved reviewing and classifying features on medical records for different tasks from patient eligibility to phenotypes extraction.

We have designed FASTVISU as an application that connects NLP outputs with free-text from CDW and provides an interface to efficiently select a set of interesting features. FASTVISU allows a single or multi-user evaluation of several features at the same time at the patient, visit or document level, based on a voting mechanism. In the next sections, we will describe the architecture of FASTVISU, and present a use case on the annotation of a cohort of patients with the Celiac Disease.

Material and Methods

Architecture

The modular FASTVISU architecture is based on a Web Service delivered as a PHP REST API. The API provides abstraction layers to:

- Retrieve documents from an i2b2 CDW;
- Create, modify and retrieve corpora of documents (stored in an Oracle database);
- Vote on features to classify patients (e.g. to select patients having a diagnosis of interest), encounters (e.g. to differentiate normal follow up encounters from relapses) or documents (e.g. classify legally conform documents from non-conform during an administrative audit). Votes are stored in an Oracle database.

554
The clients using this API are of two types:

- A user interface for human interaction (Figure 2)
- *bots* who automatically go through every document and vote according the computation from text mining modules.

![Diagram of FASTVISU architecture](image)

**Figure 1.** Modular architecture of FASTVISU.

![Screenshot of web client](image)

**Figure 2.** Screenshot of the web client visualizing a whole patient record on the left panel (using regular expressions from the text processing module to highlights concepts). The panel on the right summaries instances of concepts (color coded) and provide the user with voting options for the different categories of concepts (e.g. ‘presence of Type 1 Diabetes Mellitus: Yes/No’).
Clinical Data Warehouse

I2b2 is a widely used CDW which became de facto a standard over the years. The database of the CDW at HEGP contains data for more than 700,000 unique patients. Data available include full medical and administrative records (for in- and out-patients), diagnoses and procedures codes, EHR, structured observations, free-texts (discharges, letters), laboratory tests and pathology results, as well as every drugs prescription done in the hospital.

Evaluation

We evaluated the performance of FASTVISU to help identifying the autoimmune comorbidities associated with celiac disease in the HEGP i2b2 data warehouse. Celiac disease (CD) is an autoimmune disorder induced by the intake of proteins found in gluten. Autoantibodies such as anti-transglutaminase characterize the disease as well as intestinal villous atrophy. Several autoimmune comorbidities are known to be associated with CD, such as dysthyroidism or type 1 diabetes. More precisely, the final objective was to estimate the prevalence of the 15 most frequent autoimmune diseases (AID) in a cohort of CD patients followed at HEGP, which is a French national reference center for CD.

Corpus and data processing

Selecting comorbidities from the medical literature. We used the MeSH® (Medical Subject Headings®) co-occurrence file provided by the U.S. National Library of Medicine (NLM) to establish a list of the most frequent comorbidities in CD. We retrieve co-occurrence frequencies of the MeSH main heading Celiac Disease (D002446) with all main headings children of ‘Autoimmune Disease’ (D001327), corresponding to all terms with MeSH Tree Number starting with C20.111.*. We restrained our search to the fifteen most frequent comorbidities.

Selecting the CD corpus. We extracted a CD dataset from our data warehouse. CD cases were identified via an i2b2 query based on the combination of the three following criteria: having had an hospitalization stay with ICD-10 code for CD (K90) in billing claims; one or more stay, or consultation in the gastroenterology department; and at least one text document (discharge or letter) containing the term ‘celiac disease’ or its synonyms. The final corpus was made of all available medical documents for the patient identified by the previous query.

Identifying AID comorbidities in structured data. We leveraged two sources to identify comorbidities in patient: ICD codes from billing system, drugs prescribed and dispensed at the hospital (limited to insulin and levothyroxin). We used the UMLS to map the MeSH terms to the controlled vocabularies used in the CDW, namely ICD10 for diagnoses and ATC for drugs. We used an R script interacting with the voting module from FASTVISU to automatically record identified comorbidities with the corresponding patient.

Preprocessing free text for AID comorbidities identification with FASTVISU. We used a regular expression module for entity recognition. We elaborated a list of regular expressions (regex) for each auto-immune disease. The voting bot using the regex text processing module filtered out documents without any regex match. Expressions and keywords associated with the diseases targeted by the regex were broad to avoid any decrease in sensitivity. We expect the specificity to be near 100% because the set of documents is manually reviewed by experts (establishing a gold-standard).

Review using FASTVISU web interface.

Two trained physicians, with a background in epidemiology and medical informatics, independently reviewed the corpus of documents using the FASTVISU web client. FASTVISU presents all documents from a patient in a chronological order in the left-hand side panel of the screen (see Figure 2). Keywords and expression detected by the regex modules are highlighted. These highlighted concepts are also summarized on the right-hand side panel of the application (and provided with a clickable link to the corresponding occurrence in the text). Each occurrence (e.g. insulin) is associated with a broader category (in this study an auto-immune disease, e.g. diabetes).

After a careful review of set of documents, the reviewer can vote for the presence or the absence of phenotypes and diagnosis. At the end of this step, each patient is characterized by a vote for the presence (or absence) of each of the fifteen diseases, from each of the reviewer (and from the automatic bot voting process).

The next step is the obtention of a consensus between reviewers. This is done in FASTVISU by visualizing only the differences between the two reviewers’ votes. Reviewers will analyze and discuss their choice and agree upon a final decision.
For analysis, the API can export votes. The R statistical software can retrieve poll results directly from the API and can compute prevalence, compare sources of vote (types of codes, human text review).

**Results**

Our cohort contained 741 patients, constituting a corpus of 6340 text documents. The collection is mainly made of consultation summaries and letters (44.9%), and discharge summaries (15.3%). Median number of documents per patient was 5, IQR [3; 10] with a maximum of 146.

The bot filtered the initial corpus, using the regex module, into a corpus containing 847 documents from 276 patients’ records.

Manual review using the web client interface took two hours and two and half hours respectively for each physician. The mutual agreement on the identification of the presence of the 15 auto-immune diseases for the 276 patients was excellent (with a Cohen’s kappa of 0.89).

**Discussion**

*Elements contributing to decrease the review duration.* The human expert time required to manually review was very low thanks to two mechanisms: the automatic selection and pre-identification of relevant entities through regular expressions. First the voting bot filtered records without mention of any of the diseases or concepts related to the disease. Manual review on the remaining documents is fast because the interface presents whole the records on one single page, with links to highlighted occurrences of medical terms of interest. The UI is also conceived to integrate all functionality on a single page to allow fast transition from a patient to the next.

The time spent is neither comparable to retrospective review of paper records, nor to review from the interface of the EHR software, for which the physician would have to find patients one by one, opening every document and voting on a separate application. The best gold standard method, blinded double reviewing \(^2\), is accessible with very reasonable experts effort involved.

Compared to fully automated NLP solutions, human time spent is higher, but human interpretation remains the gold standard, thus confidence in the results is higher with FASTVISU.

Inter-annotator agreement between the two physicians was high. Differences were mostly pointed associated with ambiguous text.

*Technical significance.* The architecture of FASTVISU is flexible. The core REST API can be easily connected to any CDW. In the current architecture, the API queries a relational database (using the i2b2 star-schema). The API could be easily modified to query other types of storage system, including NoSQL databases. In the current version, we used a regex approach know to have a good sensitivity with a potentially low specificity. Thanks to a flexible architecture, adding new “sources” of concept could be easily done (i.e. using external NLP processes to identify concepts in the documents). Our goal is to provide several ways to feed the system (for different purpose).

*Clinical significance.* FASTVISU has been developed at HEGP only recently, but is already used in several studies at the Department of Medical Informatics. It can cover many different cases for a wide range of applications (including patient selection, visit selection, phenotype annotation at patient or visit level).

*Limitation.* The system is at an early stage of development and is not completely integrated in the workflow. We plan to store the results of patient selections in the CDW for later reuse. The system today does not allow voting for single concept occurrences, therefor does not yet allow validating an automatic annotation. Voting on a set of mixed typed entities (text, lab result, care procedure, drug prescription) is not implemented yet, and validating a billing system is not yet feasible. We plan to add these new functionalities in the next version of the software.

*Perspective.* Today, results collected using FASTVISU are not recorded in our CDW. We plan to “close the loop” and to export the results of extractions or patient selection in i2b2. This would allow leveraging concept manually validated in for other usage. We also plan to provide the user with information not only from the text reports but also from other sources, such as structured data, directly in the interface. The combination of complementary sources of information would give a broader and more complete perspective to the reviewers. Our short term perspective is to connect community-issued NLP tools to FASTVISU (as text processing module in FASTVISU, see Figure 1). FASTVISU modular architecture should enable the creation of such connectors easily. Additional automated modules (bots) could
augment the scope of the software. For example, FASTVISU could be used as a workbench to evaluate or to use machine learning algorithms on a set of selected documents.

Conclusion

Cohort selection, phenotypic annotations, validation of concept detected through NLP methods are common tasks in clinical research. FASTVISU allow to easily review set of patient documents, and to vote at different levels of granularity (patient selection in a cohort, encounter selection, phenotype presence or absence). FASTVISU was built upon a REST web-service API, which allows connecting a web-client with several components: a web client, an entity recognition module and a voting module. In this study, we showed that FASTVISU can be used to efficiently detect the presence of auto-immune diseases from a large cohort of patients.

Supporting Clinical Cognition: A Human-Centered Approach to a Novel ICU Information Visualization Dashboard

Anthony Faiola, PhD MFA1, Preethi Srinivas, PhDc MS1, Jon Duke, MD MS2
1Indiana University School of Informatics and Computing (IUPUI), Indianapolis, IN; 2The Regenstrief Institute, Indianapolis, IN

Abstract
Advances in intensive care unit bedside displays/interfaces and electronic medical record (EMR) technology have not adequately addressed the topic of visual clarity of patient data/information to further reduce cognitive load during clinical decision-making. We responded to these challenges with a human-centered approach to designing and testing a decision-support tool: MIVA 2.0 (Medical Information Visualization Assistant, v.2). Envisioned as an EMR visualization dashboard to support rapid analysis of real-time clinical data-trends, our primary goal originated from a clinical requirement to reduce cognitive overload. In the study, a convenience sample of 12 participants were recruited, in which quantitative and qualitative measures were used to compare MIVA 2.0 with ICU paper medical-charts, using time-on-task, post-test questionnaires, and interviews. Findings demonstrated a significant difference in speed and accuracy with the use of MIVA 2.0. Qualitative outcomes concurred, with participants acknowledging the potential impact of MIVA 2.0 for reducing cognitive load and enabling more accurate and quicker decision-making.

Introduction
Several decades of emerging bedside monitoring devices (BMD) and electronic medical record (EMR) systems have provided intensive care unit (ICU) clinicians with a range of tools that display and intelligently filter data in ways that enhance patient diagnosis. As part of the greater decision-making process, clinical decision-support (CDS) systems have also provided diagnostic tools to identify and analyze patient data through the use of algorithmic rules within a knowledge base. In spite of advances in display technology, the perceptual clarity of visually represented clinical data on LED displays (associated context-sensitive information) continues to be of low quality. (Figure 1.) These constraints have added to ongoing cognitive overload for ICU clinicians, thereby increasing diagnostic error, particularly errors of omission. Correlated to an annual mortality rate of 12-22%, human factors studies have demonstrated that 80% of “user error” is attributable to cognitive overload. These challenges create the potential for missing critical signs of an unrecognized deadly medical condition.

Figure 1. Four interfaces commonly seen in the ICU that present patient data in an array of visual configurations for various purposes: (A) BMD of patient vital signs, (B and C) EMR data and information displays that provide varying levels of clinical decision-support functionality, and (D) Medication pump display (top) and respiratory pump display (bottom).

The Institute of Medicine (IOM) states that the greatest contributor to cognitive load during data extraction and diagnosis is inadequately designed interfaces of bedside devices. In addition to time constraints, work-place interruptions, and BMD alarm fatigue, cognitive filtering strategies are often applied by clinicians as workarounds that severely constrict their analytical capacity. In each case, an assault on the clinician’s visual recognition processor, working memory, and concentration is ongoing due to cognitive loads that exceed human capacity. As a result, the clinical need to process patient information quickly and easily are unmet at critical times of diagnostic decision-making.

Adding to clinician cognitive load is the complexity of the ICU environment, where patients require constant monitoring (by multidisciplinary team members) and support through continuous bedside-care, frequent intervention, and analysis of non-electronic and device-generated diagnostic testing data. Although ICU patients are the most tested and examined of all hospital patients, important medical conditions and physiological deteriorations are (at times) overlooked. In sum, numeric and textual data analysis by clinicians results in excessive cognitive strain and irregular thinking patterns, all of which impact the quality of care and patient safety. The domains of critical care medicine and health informatics have
enormous potential for leveraging and transforming a plethora of patient data/information through the use of human-centered
designed visualization technologies that are smart, mobile, and easy to extract relevant patient-centered knowledge.

With these challenges, this paper is a review of the design and testing of a novel ICU patient information visualization
tool. Intended to support clinician cognitive load and reduce decision-making error, the tool was designed to spatially and
temporally organize contextual patient data. We refer to this tool as MIVA 2.0 (Medical Information Visualization
Assistant, version two. (Figure 2 depicts the MIVA 1.0 and 2.0 interfaces.) Envisioned as a means to rapidly analyze and
interpret trends in EMR data, our goal (in designing the MIVA 2.0 dashboard) was to positively impact patient diagnostic
outcomes and ultimately patient safety by reducing the burden of cognitive strain experienced by many ICU clinicians.

Background

The National Research Council, in its 2009 report, emphasized the need to support cognition, visualization, decision-
making, and workflow optimization in healthcare by means of an effective computing infrastructure.25 Early ICU data
visualization systems were time-oriented that allowed an analysis of electronic patient records, making it easier for
clinicians to quickly assess the overall condition of a patient’s history, while also displaying data trends, significant
information and events, and spot omissions in treatment at several levels of detail and abstraction.33-25

Although critical care decision-support must be facilitated by reliable clinical data,26 information visualization can also
provide valuable assistance to a critical care team for data analysis and patient diagnosis. Notably, effective information
visualization can amplify cognitive processes by providing computer-supported visual representations of patient data. The
purpose of visualization is for rapid information assimilation, pattern recognition, and diagnostic insights derived from
examining large amounts of data. Hence, in addition to existing conventional bedside visual displays, critical care teams
should be supported by appropriate visualization systems in order to reduce user error and ease cognitive load.

Patient data placed in meaningful contexts become relevant medical information that is usable and sharable,27 from which
clinical knowledge can be derived. Through collaborative knowledge sharing, clinical practice allows distributed
intelligence to create a patient-centered community that provides clinical group problem-solving and processes such as
“reflection-in-action.” In other words, ICU information visualization can profoundly impact the predicting of clinical
events, planning the courses of action, and diagnosing patient adverse events. Moreover, the human-centered design and
usability testing of more effective BMD and EMR interfaces continues to be a priority that should support clinical
information processing, patient diagnosis, and long-term patient care.30 As such, this paper reports on a phase-two design
study that compared the usability and effectiveness of a novel visualization application (MIVA 2.0) with a paper charting
system, commonly used to support ICU patient data documentation activities.

System Description

MIVA 2.0 is a novel EMR dashboard technology,31-34 that uses a visualization engine to deliver multivariate biometric
data by transforming it into temporal resolutions. The result is a spatial organization of multiple datasets that allow rapid
analysis and interpretation of trends. Intended as a mobile technology, MIVA 2.0 was not designed to replicate existing
BMD that display patient vital sign data or CDS systems that provide recommendations through rules-based alerts or
predictive models. Rather, MIVA 2.0 was designed to optimize diagnosis speed and accuracy by rapid recognition of
essential changes in physiological data over a designated time frame, e.g., several minutes, hours, days, or weeks. Using
selection menus, ICU clinicians control the necessary data sources and density, time periods, and time resolutions to
narrow down their diagnostic target of a patient’s condition. Figure 2 illustrates the past two iterations: MIVA 1.0 and 2.0.

The MIVA 2.0 system was designed to maximize the clinician’s ability to control and compare what data is visualized
during a specific context-related patient episode or general diagnosis, e.g., during daily rounds. Building MIVA 2.0 as an
interactive prototype (using Flash ActionScript), findings from Study One (MIVA 1.0) informed the redesign of the
visualization system and interface, as illustrated in Figure 2B and Figure 3.

Method

Participants: A convenience sample of 12 clinicians (6 physicians and 6 nurses) of mixed gender from the medical
population of the Indiana University, School of Medicine and School of Nursing were recruited. A bulk email invitation
to potential participants was sent to a group of 15 clinicians known directly/indirectly by the investigators. The 12
volunteers were evenly split into two groups according to gender and profession (physician/nurse), and in the order that
their email arrived confirming their availability for the study. Hence, a control group of six and an experimental group of
six was formed. All participants had various experiences in the ICU and/or Emergency Room. Physicians and nurses
were evenly split between the two groups according to their professional backgrounds.

Study Design: Following the development phase of MIVA 2.0, a mixed-methods evaluation study, comprising of
quantitative and qualitative measures were employed to compare MIVA 2.0 with medical paper records commonly used
for patient charting. Quantitative performance measures were comprised of eight usability time-on-task (speed) test and clinical decision-making (accuracy) task questions and 31 structured usability (Likert scale) questions, and seven qualitative open-ended interview questions. The experimental and control groups completed the usability task questions and interview, while only the experimental group completed the structured usability questions. The experimental group was provided a five-minute priming session to familiarize themselves with the functionality of MIVA 2.0 (Figure 2B), while the control group was provided a five-minute priming session to understand the paper medical chart data (Figure 4).

Participants from both groups were provided a written paragraph that outlined a fictitious clinical scenario to establish the context of the medical event. (See box below.) Both the paper charts and the MIVA 2.0 system reflected the same 12 hours of charting data. In the latter case, MIVA’s patient data was pre-loaded into the system for purposes of the study. MIVA 2.0 data was streamed from a Microsoft Excel data loop that resided on the laptop computer. (Although MIVA 2.0 was designed for use on a laptop and tablet, the usability study used the former because most clinicians noted this as their primary form of reviewing patient information.) Once the participants reviewed the clinical scenario, they were provided the eight multiple-choice questions. (See the Appendix for all usability task questions.) As such, to ascertain the correct answer to the eight questions, the control group analyzed data from the paper medical charts, while the experimental group clicked through the necessary menus/controls of the interactive MIVA prototype to find and analyze data.

Figure 2. (A) MIVA 1.0 static prototype developed for PC Windows (Study: 2008) and (B) MIVA 2.0 interactive prototype developed for tablet and laptop. Core tools/functions include: 1) Vital sign pool, 2) Information-visualization timeline, 3) Data-point scrubber-bar, 4) Intervention/note icon tray, 5) 15 min. data-status, 6) New clinical note generator, 7) Current data-status, 8) Attending clinicians, 9) Time-line indicator, 10) Time resolution control, and 11) Current time /date.

**Clinical Scenario:** A 6-month old infant has undergone repair of an AV Canal. The post-operative course is complicated by pulmonary hypertension, requiring nitric oxide (iNO) to be started on the second postoperative day. On the third postoperative day you are called to the bedside at 14:15 because of an acute deterioration. The bedside nurse states that the patient’s mean arterial pressure (ABP) and mixed venous oxygen saturation (SvO₂) have declined and the mean pulmonary artery pressure (PAP) has increased over the past 15 minutes.

Test Measures and Methods for Data Analysis

*Usability (Time-on-Task) Speed Test:* Participants from the experimental and control groups were tested for execution speed, i.e., time taken to complete each task in minutes and seconds. No time limits were imposed. The Mann-Whitney non-parametric test and independent samples t-test was used to identify any significant differences in task execution speed between the two groups. SPSS v21 was used in all usability statistical analysis.
Usability (Clinical Decision-Making) Accuracy Test: Participants from the experimental and control groups were also tested for the decision-making accuracy of their responses to each of the multiple-choice questions. The response to each question was judged as either correct or incorrect. A Chi-squared test was used to identify the overall significant difference in accuracy between the experimental and control groups.

Post-Test (Context-of-Use) Questionnaire: Following the usability time-on-task and decision-making test, the control group participants were also allowed a five-minute priming session to experiment with MIVA 2.0. (We anticipated that their valued input as clinicians would provide further information (positively or negatively) regarding the potential of the system.) Hence, participants from the experimental and control groups were provided a post-test questionnaire composed of structured and semi-structured questions that addressed the context-of-use and usability of MIVA 2.0. The semi-structured questions focused more on task execution, medium of execution, learning, cognition, articulation, and long-term outcomes of either paper charts (control) or MIVA 2.0 interfaces (experimental). Participants were provided structured Likert questions (Range 1-5) and semi-structured questions, which yielded mean scores, percentages, and short comments regarding MIVA’s interface and interaction design, and overall usability.

Open-Ended (Usability) Interview: Participants from the experimental and control groups were given an interview to comment on the general functionality, usability, utility, and user experience of MIVA 2.0, as well as its potential to support clinical work in the ICU. All 12 participants were interviewed, which were video recorded and transcribed. A content analysis was done of the transcription using ATLAS.ti (v1.0.15). Participants were allowed ample time to discuss the usability, usefulness, and limitations of MIVA 2.0 and its potential use in the context of a real-world ICU environment.

Findings

The usability speed test identified no significant difference in time-on-task between the control group (M=1.30, SD=.78) and the experimental group (M=1.53, SD=.87). However, an independent samples t-test identified that the experimental group (MIVA 2.0) participants performed significantly faster, overall, than the control group in answering two questions: [Q3] t(10)=3.11, p=.011, r=.70; [Q4] t(10)=3.65, p=.004, r=.76. The clinical decision-making accuracy test identified an overall significant difference in accuracy of the eight question test between the experimental (M=.65, SD=.30) and control groups (M=.58, SD=.36): χ²(1,12)=5.04, p=.03, suggesting that the experiment group test score was more accurate than the control group. See Appendix for all eight questions.

The post-test structured questions yielded a mean response that included 67% of both the control and experimental groups reporting that MIVA 2.0 provided consistent interface and interaction sequencing. This included: clarity of wording, meaningful icons, labels positioned appropriately, requiring a minimal learning curve, and had overall positive feelings towards the interface based on their experience. Also, 83% of all participants reported minimal user action required in using MIVA 2.0. Regarding post-test semi-structured responses, participants noted that MIVA 2.0 provided five interface elements or functions that added to its potential as a clinical information dashboard:
1. MIVA 2.0’s information visualization points were easily accessible and without the need to additionally review traditional paper charts,
2. MIVA 2.0’s clinical use was consistent with ICU clinical practice,
3. MIVA 2.0 provided easily understandable icons that represented clinical interventions such as lab work, x-rays, meds, etc., which provide external clues about group work, coordination, and communication,
4. MIVA 2.0 provided easy access to externally distributed knowledge (e.g., clinical notes port in through the electronic medical record system), and
5. MIVA 2.0 was a solution to resolve conflicts about interpreting others’ activity.

NOTE: Seventy-five percent of all participants agreed that current approaches to collecting and presenting ICU critical care data is not sufficient for supporting accurate diagnoses or management of the critically ill. They also made comparative comments about the importance, limitations, learnability, and long-term consequences of paper chart verses MIVA 2.0. See Table 1.

Content analysis of transcribed interviews yielded in-depth participant perceptions of how MIVA 2.0 might successfully or unsuccessfully integrate into the ecological space of the ICU. Five major themes emerged from our qualitative analysis, which we describe in detail below. (Also see the visual representation of these five themes in Figure 6.)

The themes include: (1) MIVA 2.0’s potential for providing current information tools and needs, (2) Current division of labor in the ICU, (3) Implicit and explicit rules, strategies, and checklists currently used in the ICU and MIVA 2.0 complementing them, (4) Changes to the clinical practices and outcomes brought about by MIVA 2.0, and (5) Drawbacks of the changes caused by MIVA 2.0 to the ICU ecological space.

(1) Current information tools and needs. As a preface to their comments on MIVA 2.0, participants reported that paper and electronic tools were the current standard of use in the ICU. They also noted that strips of paper are used owing to ease of data entry, while health information technology, (e.g., bedside devices and EMR systems) are also used to display and store massive patient datasets in addition to clinician orders. Participants stated that although paper offered a natural affordance and was convenient with respect to recording data, data access and interpretation and sorting through complex data was limited. The visualization component of MIVA 2.0 was reported as easier to interpret at a glance and helped sorting through complex datasets.

Participants also agreed that MIVA 2.0 had the capacity of complementing the current information and cognitive needs of ICU clinicians. Overall, participants showed a positive attitude towards the interface look/feel, interaction sequencing, and the learning curve of the MIVA 2.0. Participants reported becoming familiar with MIVA 2.0 with minimal effort. There were, however, minor differences with respect to the cosmetic interface and interaction sequences between the control and experimental participants. Thus, while the overall look and feel was stated as intuitive, clear and easy to understand by the control participants, the experimental participants remarked that the appearance and behavior of the interface still had several issues to overcome. For instance, control group participant P3 (experimental group) and P4 (control group) stated:
“You need to use color sparingly. I think the use of color is smartly done here. There are not too many different colors. And so the colors are used strategically to facilitate decision-making. The contrast seems appropriate with the colors chosen. The data is easy to manipulate, allowing me to see a different time scale.”

“MIVA should be tested with a scenario with many more data points, e.g., more clinical notes. Most ICU patients, if they are there for more than a week, will have more than a 1000 notes. Can you put 1000 icons up there? ...Maybe you have to group them.”

Participants stated that MIVA 2.0 increased efficiency when compared to current tools with respect to time expenditure and that it contributed to reduction in the cognitive effort, which is needed for data interpretation and decision-making as compared with the current electronic tabular formats and/or paper charts. For example, P6 stated,

“One ends up looking back at each number in a tabular format, similar to paper format. You could do some simple graphing of the data over time, which wasn’t terribly intuitive or usable. One is left with using tabular data. The graphical representation to my eye looks much easier to interpret when comparing variables.”

(2) Division of labor. Participants reported the potential of MIVA 2.0 to support ICU collaborative working patterns (and workflow overall), where multidisciplinary teams of clinicians coordinate during rounds to understand, discuss, and administer patient care. Participants also perceived MIVA 2.0’s potential to support the handing-off process during the change of shifts, commending MIVA 2.0’s ability to off-load manual data-entry of patient information by nurses. For example, P1 stated,

“These data points/graphs across the top, in terms of clinical notes or x-rays taken or medications, allows you to see what data is in relation to each other. For example, if a nurse performs a certain task using certain parameters he/she can get better at understanding the patient data after the fact without having to communicate directly with others about the information. So you have the presentation of all the information from all of those different groups all in one simultaneous place that would allow for enhanced deliver of care.”

(3) Implicit and explicit rules, strategies, and checklists. Participants stated MIVA 2.0 would be useful in following requirement guidelines and checklists (dictated by hospital administration), specifically to ensure that all patient care follows established protocols in administering medications. For example, P10 explained,

“From a physician’s standpoint, it’s the overall care that is important; e.g., if they are on a ventilator we have a checklist to go through to determine if they have had the daily weaning of their sedation. We look at ventilator settings to see if there is an ability to take them off based on a couple of parameters… It (MIVA 2.0) would be helpful for some of our weaning off of the ventilator, i.e., by having information displayed over time you can compare it to previous day.”

(4) Changes in clinical practices and outcomes by MIVA 2.0. Participants reported the shift in clinical practices towards more time being spent on analyzing patient data and making more informed decisions as a result of MIVA 2.0. For example, P6 stated,

“After people get used to MIVA, they will make more educated decisions based on the patient’s status. They would be able to spot trends sooner or more accurately than compared to the tabular data. Then hopefully in the long run, improve patient outcomes… If you are able to take this with you on your rounds on a tablet, this would allow clinicians to be more informed throughout the rounds, thus allowing you to make more accurate or quicker decisions in terms of care management… That would make sense if you were able to see the data, the trends and the relationships easier, i.e., you would be able to address the problems sooner and more efficiently, thereby, hopefully, improving outcomes.”
(5) Drawbacks of changes to the ICU ecological space caused by MIVA 2.0. Although overall participants expressed positive attitude towards the inclusion and usage of MIVA 2.0 in the ICU, they were some who expressed concern over the increased interactivity and access to patient information. For example, P2 contradicted P6:

“...the tradeoff is the extent by which MIVA distracts the team from engaging with one another. I don’t like it when I am working with a distracted team member. I don’t like it when I am working with a resident that is looking up the labs in the middle of discussing the case. So, they may not be engaged to the extent to which they should be if they are using these visualizable tools, i.e., a potential trade-off would be their distraction from engaging with one another.”

Discussion and Conclusion

This paper described the testing of MIVA 2.0, an information visualization dashboard tool for the ICU. A mixed methods approach comprised of performance/usability testing, post-test structure and semi-structured questionnaires, and open-ended interviews were conducted. Findings suggest that MIVA 2.0 has the potential to out-perform the use of paper charts (or other electronic one-way data input devices) in retrieving and analyzing patient data. Participants also noted that MIVA 2.0 was designed with a keen awareness of the broader context for the (real-world) ICU experience; and as such, has the potential to support a rich social matrix of clinical activity. Further, there was concurrence that MIVA 2.0 showed promise for significantly impacting clinical decision-support, as well as improving clinical workflow effectiveness. One participant suggested that adhering to internal workflow practices would also help MIVA 2.0 integrate seamlessly into the current ICU EMR system, provided the visualization paradigms used are carefully balanced between being informative and visually distractive.

All the participants agreed that MIVA 2.0 has the potential to change current ICU clinical practice through the emergence of new analyses and reduced time and effort in placing requests for data. They noted that this might also lead to changes in the function of some of the clinical roles in the ICU environment. The participants, however, suggested that integrating predictive clinical rules and providing a mechanism for the clinician to customize the tool (e.g., setting alerts) would lead to better decision support and patient care. In addition, participants noted scalability and programmed spontaneity as potential challenges that might be faced when MIVA 2.0 is implemented. Additional, however, the authors believe initial tool learning may impact cognitive load.

Limitations of the study relate primarily to this early stage of development of the visualization prototype, a relatively small sample size, and the use of a single clinical scenario. As such, our study should be expanded to include more advanced computer prototypes, a larger sample size, and a broader range of problems, ideally from several clinical ICU settings that require collaboration with intensivists across teams and physical locations. Further limitations of the study relate to lack of consideration for communication and collaboration between the critical care team members in the ICU. For example, during the open-ended interview sessions, participants discussed the need for frequent communication between the team members as a critical component of ICU collaborative processes. For instance, if there is the need for frequent communication between the respiratory therapy team, physical therapy team, nursing team and medical team, MIVA 2.0 could provide specific tool functionality that would facilitate greater interaction and access to workflow information.

Underscoring the importance of these latter findings (related to communication and collaboration), the authors have begun a review of significance of integrating communication-information technology (CIT) into the existing MIVA framework. In further support of a revised model, studies have shown that a major source of workflow error and cognitive strain is related to communication and collaboration breakdown. These findings state that 91% of all medical mishaps are due to communication difficulties and inefficient team collaboration and decision-making. Communication among clinicians, including but not limited to face-to-face interaction, is often interrupted and of poor quality. This has lead to inefficiencies and potential error in the ICU, where rapid and accurate communication is essential for delivering safe patient care. Also, inadequate and inefficient collaboration among nurses and doctors increases the average length of stay of patients, leading to severe inconvenience and greater patient mortality. Direct verbal communication is one of the chief sources of trust building among ICU clinicians, which fortifies work relationships and cognizance of others’ expertise, leading to increased collaboration. In sum, it has been found that ICU clinicians using CIT improve team relationships, staff satisfaction and patient care. Such technologies can improve communication speed by 92%, communication reliability by 92%, coordination by 88%, reduced staff frustration by 75%, and faster and safer patient care. In addition to the above discussion and limitations of MIVA 2.0, MIVA 3.0 is currently being designed to include communication functionality. Since nurses and physicians hold different abilities and experiences of clinical decision-making, good communication and collaboration between multidisciplinary teams is essential. Hence, communication among clinical staff should consist of more than face-to-face, but also incorporate the use of synchronous and asynchronous CIT (e.g., smartphone, email, text and video conference) in order to optimize and enable bi-directional,
rapid, secure, and non-disruptive transmission of content-rich messages, for purposes of expediting and increasing the accuracy and effectiveness of decision-making.45

While the study in this paper focused on usability, user experience, and reducing cognitive load and time spent in analyzing patient data, our assessment only indirectly addressed MIVA’s impact on workflow. For this reason, the author’s current development of MIVA 3.0 includes the goal of optimizing real-time diagnostic solutions during clinical workflow. The primary aim of this work will firstly uncover evidence from three hospital ICUs to more precisely determine how to model workflow, using methods that include ethnographic observation, shadowing and self-reporting interviews. The Experience Sampling method will also be used to collect data on clinician cognitive load and decision-making. From this data, we will construct workflow models that comply with IOM recommendations for ICU patient safety and clinical effectiveness and efficiency.46 ICU workflow models will provide the underlying groundwork for the design of the MIVA 3.0 prototype, followed by a series of comparative (clinical scenario) studies to evaluate the impact of the prototypes on team performance.

APPENDIX

MIVA In-Lab Scenario / Usability Time-on-Task/Speed and Decision-Making/Accuracy Test Questions
For Experimental Group (MIVA) and Control Group (Paper Chart)

1. What is the current ventilator rate (RR)? a) 16, b) 18, c) 24, d) 22, e) 14
2. What was the mixed venous oxygen saturation at noon yesterday? a) 65%, b) 70%, c) 75%, d) 80%, e) 85%
3. When (day / approximate time) did the pulmonary artery pressure begin to increase? a) Post op day 1, early afternoon, b) Post op day 1, late afternoon, c) Post op day 2, early morning, d) Post op day 2, late evening, e) Post op day 3, Noon
4. When was inhaled nitric oxide commenced? a) Post op day 2 - 0100hrs, b) Post op day 2 - 0800hrs, c) Post op day 2 - 1200hrs, d) Post op day 2 - 1400hrs, e) Post op day 2 - 2000hrs
5. What was the starting dose of inhaled nitric oxide? a) 20ppm, b) 25ppm, c) 15ppm, d) 40ppm, e) 30ppm
6. What happened to the mixed venous oxygen saturation after starting nitric oxide? (Context: Transient is defined as <30minutes; Sustained is defined as >30minutes) a) Sustained decrease, b) Sustained increase, c) No change, d) Transient decrease, e) Transient increase
7. What event precipitated the most recent acute deterioration? a) Withdrawal of iNO b) Ventilator rate weaning, c) Increase of iNO dose, d) Increase of ventilator rate, e) Insufficient data presented
8. How does the current mean PA pressure compare to the mean systemic pressure? a) PA pressure ~1/3 systemic, b) PA pressure is supra-systemic, c) PA and Systemic pressures are equal, d) PA pressure is 2/3 systemic, e) PA pressure is ½ systemic

Post Test - Structured Usability and Context-of-Use - Likert Questionnaire
For Experimental Group (MIVA) [1=SD 2 = D 3 = NA 4 = A 5 = SA]

>> CONSISTENCY <<
1. Was the user feedback consistent?
2. Was the labeling configuration consistent?
3. Was the labeling and/or wording familiar?
4. Was the display consistent with clinical conventions?
5. Were the user actions required consistent?
>> LEARNABILITY <<
6. Did MIVA provide clarity of wording?
7. Was the data grouping reasonable for easy understanding and analysis?
8. Was the grouping of menu options logical?
9. Were the command names meaningful?
10. Were abbreviations, acronyms, and graphic symbols useful and clear?
11. Did MIVA provide meaningful symbols/icons for the verbal labels?
>> MINIMAL ACTION <<
12. Did MIVA require minimal cursor/pointer positioning and action?
13. Did MIVA require minimal steps in sequential menu selection?
14. Did MIVA require minimal user control actions?
15. Did MIVA provide understandable hierarchic menus for sequential selection?
>> PERCEPTUAL LIMITATION <<
16. Were all or most display elements distinctive?
17. Does MIVA provide easily distinguished colors?

Post Test - Open-Ended Interview Questions
For Experimental Group (MIVA) and Control Group (Paper Chart)
1. What was your immediate impression of MIVA?
2. Did you enjoy using MIVA?
3. What did you like the most/least about the MIVA?
4. How would you grade MIVA’s easy of use? A B C D F
5. What was your first impression about the colors, type, interface layout, and interactive tools of MIVA?
6. Did you understand how to use the menus and buttons right away?
7. What did you think were the biggest problems with MIVA?
Automated mutual exclusion rules discovery for structured observational codes in echocardiography reporting

Abstract

Structured reporting in medicine has been argued to support and enhance machine-assisted processing and communication of pertinent information. Retrospective studies showed that structured echocardiography reports, constructed through point-and-click selection of finding codes (FCs), contain pair-wise contradictory FCs and reliability thereof. In a prospective study, contradictions were detected automatically using an extensive rule set that encodes mutual exclusion patterns between FCs. Rules creation is a labor and knowledge-intensive task that could benefit from automation. We propose a machine-learning approach to discover mutual exclusion rules in a corpus of 101,211 structured echocardiography reports through semantic and statistical analysis. Ground truth is derived from the extensive prospectively evaluated rule set. On the unseen test set, F-measure (0.439) and above-chance level AUC (0.885) show that our approach can potentially support the manual rules creation process. Our methods discovered previously unknown rules per expert review.

Introduction

Structured reporting in medicine has been argued to support the communication process through the use of common report structure and standardized vocabulary, and ideally allows for automated processing and re-purposing of its content to drive downstream clinical, research and operational workflows1,2. A commercial echocardiogram reading and reporting solution (Xcelera, Philips) supports construction of structured reports through selection of site-specific finding codes in an anatomically organized point-and-click interface. A finding code (FC) corresponds to a unique observational or diagnostic statement that has a narrative, one-sentence description, e.g., “Injection of contrast documented no interatrial shunt” and “The prosthetic mitral valve appears to function normally”.

In this paper, we explore if patterns between FCs can be discovered in a large corpus of structured echocardiography reports that represent actionable clinical knowledge. In particular, we shall focus on patterns of the form “FCs A and B are mutually exclusive”. Such patterns may depend on straightforward interpretation of the lexicon, e.g., “Left ventricle is moderately dilated” and “Left ventricle is severely dilated”, or on a more complex understanding of the domain and its pathologies, e.g., “There is severe aortic root dilatation” and “The aortic root is normal in size”.

Rules of the form “FCs A and B are mutually exclusive” can be leveraged to alert the echo reading cardiologist when his/her preliminary report contains both FCs A and B. Automated discovery of such rules can replace or assist a human domain expert in authoring such quality assurance (QA) rules.

Retrospective studies have shown that structured echocardiogram reports contain pair-wise contradictory FCs, which lead to confusing report content3. This, in turn, may negatively affect the referring physician’s perception of the echocardiogram interpretation results, may require additional avoidable communication to resolve the confusion, and, if undetected, may impact patient care.
To detect and resolve contradictions within the report, a plug-in to the echo reporting solution was devised in prior work that compares a set of QA rules against the report’s FCs. If any of the rules is violated, the user is alerted and options are presented to resolve the violation. The plug-in was prospectively evaluated in the clinical workflow at the University of Chicago Hospitals (UCH) in the course of 15 months, showing that on average 2.4 conflicts were detected per echocardiogram and that 83% of reports contained at least one conflict. The QA rule set driving the plug-in was created and maintained manually. This process was labor intensive and required expert resources with deep domain knowledge. Rules created at one site cannot generally be transferred to other sites as FC vocabularies are configurable and therefore locally idiosyncratic. If successful, our methods can be leveraged to support the manual rules creation process by proposing automatically derived mutual exclusion rules.

We will approach mutual exclusion rule discovery as a binary classification problem and address it using machine learning techniques. To separate clinically valid rules from nonsensical rules, we use semantic and statistical methods to characterize potential rules. The semantic methods are motivated by the fact that contradictions between FCs manifest in the combined meanings of their respective descriptions. The statistical methods are motivated by the fact that correct reports do not contain contradictory FCs and the assumption that they are therefore less likely to co-occur than non-contradictory FCs, relative to a priori prevalence.

This paper addresses the following three research questions:

1. Can mutual exclusion rules be discovered using standard machine learning techniques?
2. What is the impact on classification performance of the semantic and statistical characterization methods?
3. Can the proposed methods discover mutual exclusion rules that were not in the ground truth QA rule set?

This work contributes to the research program of exploring and evaluating methods that extract meaningful information and knowledge from corpora of medical information with the purpose of leveraging the extracted patterns to increase the effectiveness and efficiency of healthcare delivery.
Figure 2. Popup that alerts the user that a combination of FCs violates one of the quality assurance rules. This violation can be resolved by selecting one FC and pressing the “Keep Single Selection” button, which results in removal of the other FC. The FCs are presented to the user in their shorthand notation, i.e., internal identifier (“TV600.1”) and brief description (“No TR”).

Methods
Corpus and problem definition
An anonymized corpus of 101,211 structured echocardiogram reports was made available by UCH, in which each report was represented as a list of FCs.

A QA rule set was made available by UCH with the same FC lexicon as the report corpus. This QA rule set had been deployed clinically to prospectively detect inconsistencies in 7,986 reports in the course of 15 consecutive months. The QA rule set contained 580 rules, each was of the form “If {all, at least one} of FCs A₁, ..., Aₙ are contained in the report, then {all, at least one, none} of FCs B₁, ..., Bₙ are contained in the report” and “FCs A₁, ..., Aₙ are mutually exclusive”. Using propositional reasoning patterns, all mutual exclusion rules implied by the QA rules were extracted. For instance, the rule “FCs A, B, C are mutually exclusive” implies that the pairs A-B, A-C, and B-C are mutually exclusive. In this manner, the QA rules generated a multitude of simple rules. In this research, only simple rules of the form “FCs A and B are mutually exclusive” were considered, where A and B were “binary” FCs, i.e., FCs that are either contained in a report or not, as opposed to measurement FCs such as “Left ventricular ejection fraction is ____”. The resulting rule set accounted for part of all violations detected by the complete QA rule set in the prospective study.
Each rule in the initial QA rule set was labelled Mandatory or Suggestion. Violations of Mandatory rules had to be resolved prior to finalization of the report whereas violations of Suggestion rules could be ignored. The rule labelling carried over to the mutual exclusion rule implied by each individual rule.

A rule instance is a rule of the form “FCs A and B are mutually exclusive” for any two distinct FCs A and B. A set of N unique FCs gives rise to N(N − 1)/2 distinct pairs of FCs. A rule instance is Mandatory if it is a Mandatory rule in the QA rule set; it is Suggestion if it is Suggestion in the QA rule set; and, it is unaccepted if it is neither Mandatory nor Suggestion.

We define the QA rule discovery problem as the binary classification problem of distinguishing “positive” rule instances from “negative” rule instances, i.e., the non-positive instances. We shall entertain two definitions of positive instances: 1) the Mandatory rule instances (M mode) and 2) the Mandatory and Suggestion rule instances (MS mode).

A development (“dev”) and a complementing test set were created each comprising roughly half of all labelled rule instances. The dev set was for feature engineering and creating classification models. To ensure that the semantic features were based on only part of the FC descriptions, the dev was created as follows. A random subset of FCs was taken comprising roughly 70% of all FCs, called the dev FC set. The dev set contained all rule instances with FCs A and B, for which both A and B were contained in the dev FC set, and thus contained roughly 50% of all rule instances (0.5 ≈ 0.7 × 0.7).

Feature engineering
A rule instance is characterized as a vector of values, each computed by a feature function (simply referred to as “feature”). The features were created and refined based only on the co-occurrence statistics in the dev set and the narrative descriptions in the dev FC set.

Statistical features
In the context of a corpus of reports, rule instance “FCs A and B are mutually exclusive” gives rise to standard probability metrics based on co-occurrence statistics observed in the report corpus: P(A&B), P(A&not-B), P(not-A&B), P(not-A&not-B), P(A|B) and P(B|A). For instance, P(A&B) is defined as the observed ratio of reports that contain both FC A and B, i.e., the portion of reports in which the rule at hand is violated.

To assess if the observed portion of violations P(A&B) is lower than one would expect if A and B are independent, we include the feature P(A&B)/P(A)P(B), named “O/E”. The product P(A)P(B) is the expected portion of violations, where P(A) and P(B) are the observed portions of reports containing A and B, respectively.

Finally, we include as feature the $\chi^2$ statistic that is computed from the 2 × 2 contingency matrix defined by the co-occurrence counts of A and B. This feature quantifies the level of correlation between A and B.

Semantic features
Identical Modulo Keyword (“IMK”). Boolean feature that returns “true” if the descriptions of two finding codes are identical except for a severity keyword, e.g., “LV moderately dilated” and “LV severely dilated”. Conflicting presence and absence indicators are picked up in a similar fashion, e.g., “There is no apical thrombus” and “There is apical thrombus”.

Word Overlap Ratio (“WOR”). Numerical feature that measures the syntactic similarity between the FCs’ descriptions as the ratio between the number of unique words they have in common and the number of unique words that appear in either of them. Stopwords are eliminated in this count and words are stemmed to account for lexical variation. This feature maps two FCs onto a value in [0, 1], where 0 indicates minimal word overlap (no words in common) and 1 maximal word overlap (identical words).

Anatomical Distance (“AD”). Numerical (integer) feature that measures the distance between the FCs’ anatomical regions as the number of anatomies traversed as blood flows from the upstream to the downstream anatomy in a normal heart. The following anatomies were accounted for: Vena cava → Right atrium → Tricuspid valve → Right
ventricle → Pulmonic valve → Left atrium → Mitral valve → Left ventricle → Aortic valve/Coronary cusp. For instance, the anatomical distance between “Increased E/A ratio for age suggests elevated LA pressure” (Left atrium) and “Cannot exclude aortic valvular vegetation” (Aortic valve) is 3.

Mentions of anatomical regions are recognized in the FC description by means of regular expressions that account for common spelling variations based on the FC descriptions in the dev set and online background resources. If no anatomical region is recognized in either one FC description, AD was −1.

Evaluation

Model evaluation
One Random Forest (RF) classification model was created using the dev set in which the Mandatory rule instances were considered the positive instances (M mode), and another RF model was created in which the Mandatory and Suggestion rule instances were considered the positive instances (MS mode). Each model was then evaluated against the test set in the respective mode. To address the first research question, standard methods of evaluation were used: precision, recall, F-measure and area under receiver-operator curve (AUC). In a similar fashion, two Ripper models were created and evaluated. All models were created and evaluated in Weka (version 3.6.11). The RF classifiers were created using 100 trees, unlimited maximum depth, and \( \log_2(N) + 1 \) features considered at each node, where \( N \) = total number of features. The Ripper classifiers were created using 3 folds (2 for growing and 1 for pruning), 2 optimization runs and minimum weight of 2 for the instances in a rule. To address the second research question, every experiment run was executed another two times with feature vectors constrained to the semantic and statistical features.

False positive review
For each of the four evaluation runs (RF/Ripper and M/MS), the false positive rule instances were collected, i.e., the negative rule instances that were marked as a rule by the classifier. The resulting list of false positives was presented to the attending cardiologist who created the QA rule set (KTS). To address the third research question, the reviewer considered each false positive and assessed if it could be adopted as a rule and, if so, with Mandatory or Suggestion status. The acceptance rate was computed for each classifier as the percentage of accepted rule instances.

Results

Characteristics dev and test set
The corpus consisted of 101,211 structured echocardiogram reports comprising 850 unique FCs, which gave rise to 360,825 (= \( N(N-1)/2 \), where \( N = 850 \)) rule instances. The dev set contained 186,355 (= \( 611 \times 610/2 \)) rule instances based on a randomly selected subset of 611 FCs amounting to 71.9% (= 611/850) of the total number of FCs. The test set contained the remaining 174,470 (= 360,825 − 186,355) rule instances. From the initial QA rule set, 2,485 Mandatory and 658 Suggestion mutual exclusion rules were extracted. Table 3 contains the descriptive statistics of the dev and test set.

Feature properties
In the \( \chi^2 \) analysis of the features in the test set, the features IMK, WOR and O/E are most strongly correlated with the positive instances defined as the Mandatory (M mode) or Mandatory and Suggestion (MS mode) rule instances. The feature \( P(A&B) \) is ranking 11th and last in both modes.

The semantic features rank 1st, 2nd and 5th in decreasing order of \( \chi^2 \) value, in M mode and 1st, 2nd and 4th in MS mode. In both modes, O/E is the highest ranking statistical feature, see Table 2.

Key descriptive statistics of select features on the test set are given in Table 3.

WOR and O/E have an uninterrupted value range in which the Mandatory and Suggestion rule instances outnumber unaccepted rule instances, see Figure 3. For WOR, this interval is [0.6, 1], which covers 0.2% (= 362/174,470) of all rule instances, 16.7% (= 193/1,159) of Mandatory rules instance and 0.0% (= 0/325) of Suggestion rule instances. For O/E, this interval is [0.002, 0.046), which covers 0.2% (= 272/174,470) of all rule instances, 11.5% (= 133/1,159) of Mandatory rule instances and 2.1% (= 7/325) of Suggestion rule instances.
Classification results
The two classifiers were evaluated in both modes on the test set, which was disjoint from the dev set. Performance metrics are given in Table 4. Optimal classification performance is achieved by RF using both semantic and statistical features (F-measure 0.439 and AUC 0.885).

Combining the semantic and statistical features generally results in superior performance compared to characterization of rule instances through either method in isolation. When only semantic features were used, the vast majority of rule instances classified as positive had positive IMK value, i.e., the descriptions of the FCs in the rule were identical modulo a severity indicator (ranging from 87.6% [= 176/201] for RF to 100% [= 176/176] for Ripper both in MS mode). This resulted in high precision values (0.834 to 1, see Table 4) but low recall (0.109 to 0.158, see Table 4).

RF outperforms Ripper on most F-measure scores and all AUC scores. In fact, Ripper’s AUC scores indicate no (0.569 and 0.571, on statistical features, see Table 4) to poor (0.625 and 0.639, on all features) predictive performance. RF’s AUC scores indicate fair (0.721 and 0.732, on statistical features) to good (0.869 and 0.885, on all features) predictive performance.

In all four classifier–mode combinations, precision trumps recall. Highest precision was 0.689 and highest recall was 0.322, both for RF in mode M with all features.

False positive review
Due to a technical insufficiency the false positives were only partially reviewed by the attending cardiologist. The acceptance rates of the reviewed false positives is presented in Table 5 for both classifiers. For RF, 33.0% and 37.6% (= 26.3 + 11.3) of false positives were accepted as clinically valid rules in mode M and MS, respectively. For Ripper, the acceptance rates are slightly higher: 34.9% and 42.9% (= 33.0 + 9.9) in the respective modes.

![Distribution of WOR over rule instances](image1)

![Distribution of O/E over rule instances](image2)

Figure 3. Histogram showing distribution of Mandatory, Suggestion and unaccepted rule instances over value ranges for the WOR (left) and O/E (right) features. In each diagram, the left-most bin has been clipped to enhance interpretability. In the WOR diagram, the Mandatory and Suggestion rule instances outnumber the unacceptable rule instances in the interval [0.6, 1]. In the O/E diagram, the Mandatory and Suggestion rule instances outnumber the unacceptable rule instances in the interval [0.002, 0.046].

**Discussion**

**Address research question**

Based on our results, we answer this paper’s research questions as follows:

1. Mutual exclusion rules can be discovered with standard machine learning techniques: An RF classifier retrieved 32.2% (recall) of Mandatory rules on unseen rule instances maintaining precision of 0.689 (Table 4).
2. Combining the semantic and statistical features results in superior performance (F-measure 0.368 to 0.439) compared to characterization of rule instances through either method in isolation (semantic: F-measure 0.197 to 0.217; statistical: F-measure 0.205 to 0.232).
3. Our methods can discover new clinically valid mutual exclusion rules that were not in an extensive manually constructed QA rule set: a domain expert accepted between 33.0% and 42.9% (Table 5) of mutual exclusion rules that were identified as clinically valid rules by the classifiers and that were not in the QA rule set.

Classifier performance for separating Mandatory and Suggestion rules from unaccepted rules (mode MS) is more unreliable than separating Mandatory rules from Suggestion and unaccepted rules (mode M). We hypothesize that this is because Suggestion rules are essentially a different concept than Mandatory rules, as they can co-occur. This seems also to be reflected by the descriptive statistics in Table 3: the average Suggestion values typically sit in between the average values of the Mandatory and unaccepted rules. Mixing Mandatory and Suggestion rules creates a less coherent notion of positive instance, which is inherently harder to learn.

The statistical approach was motivated by the intuition that the FCs in valid mutual exclusion rules co-occur much less than one would expect based on joint probabilities, modelled by feature O/E. The answer to the second research questions shows that rule discovery is not only a statistical problem, i.e., it cannot be reduced to finding the optimal O/E threshold.

**Error analysis**

**False positives**

Among the reviewed false positive rule instances, we found that roughly one third had low co-occurrence ratios (i.e., low P(A&B) and O/E values) but for other causes than conflicting FCs. We identified two root causes for this statistical profile.

The first root cause is reporting convention that prohibit the use of FC combinations. For instance, “There is no gradient across the prosthetic mitral valve” and “There is no mitral stenosis” should not co-occur as a matter of convention as there is an alternative to the latter FC that specifically states absence of stenosis in the prosthetic mitral valve. In the QA rule set, such reporting conventions were not encoded.

The second root cause is (near-)tautological FC descriptions. Inclusion of (near-)tautological FCs is bad reporting style, but does not create conflicts in the report that could potentially confuse the report consumer; e.g., “The mitral valve is not well seen, but is grossly normal” and “There is no significant mitral valve disease”. In addition to not co-occurring as a matter of style, (near-)tautological FCs typically have a substantial portion of words in common, which manifests itself in increased WOR values and makes them more likely candidates for being misclassified as Mandatory or Suggestion rule instances.
False negatives

We identify three feature profiles that were common among the false negatives, i.e., the Mandatory and/or Suggestion rule instances that were misclassified as unaccepted.

First, rule instances with \( \Pr(A \& B) = 0 \) or, equivalently, \( O/E = 0 \). In case the rule instance is valid, this indicates that there are no observed violations in the report corpus; in case the rule instance is invalid, it indicates that the two FCs did not co-occur for other reasons. By definition, \( \Pr(A \& B) = 0 \) if and only if \( O/E = 0 \). Table 3 shows that the latter case is much more prevalent: 109,594 rule instances with \( \Pr(A \& B) = 0 \) were unaccepted versus 854 Mandatory and 204 Suggestion. Hence, because of the overwhelming evidence, if \( O/E = 0 \), the classifier is inclined to mark it as unaccepted. This error category accounted for roughly 74% of false negatives.

Second, rule instances with \( \Pr(A \& B) > 0 \) and negligible expected probability \( \Pr(A)\Pr(B) \), i.e., \(< 1e-5\). In this case, one mere co-occurrence of A and B vastly exceeds the number of expected co-occurrences, simply because the expected number of co-occurrence based on prior probabilities \( \Pr(A)\Pr(B) \) is negligible. This phenomenon greatly offsets the O/E feature: we found examples with \( O/E = 1686.8 \). This ratio is obviously unreliable as it is based on only one single co-occurrence, which may well have been the outcome of a chance process. This error category accounted for roughly 3% of false negatives.

Third, rule instances with \( \Pr(A \& B) \) and \( AD > 0 \). For the instances with \( AD > 0 \), 99.6% are unaccepted; this can be derived from Table 3. In addition, if \( AD > 0 \), the anatomical location descriptions in the FCs do not match. This implies that they have decreased number of words in common, which results in lower WOR values, which is suggestive of the rule instance being unaccepted, see Table 3. Lower WOR values indicates that the rule is invalid, Table 3. This error category accounted for roughly 19% of false negatives.

Real-world implications

Our results show that machine learning methods can discover mutual exclusion rules in the UCH corpus. All features are institute independent and the engine can therefore be applied to unseen report sets in the English language, even if they were written with a different FC vocabulary. This is advantageous as the proprietary echocardiogram reporting solution (Xcelera, Philips) allows for modification and extension of the FC lexicon.

Roughly 70% of rules discovered by the classifiers are clinically valid (e.g., RF’s precision is 0.689 in mode M, Table 4). Although this rate is encouraging, it may be too low to merit uncontrolled auto-population of the facilitated reporting plugin. Various strategies can be adopted to filter out the clinically valid rules. First, the discovered rules can be reviewed manually before adoption. In this scenario, the rules can be presented by decreasing certainty value so that the reviewer or review team can decide to stop validating rules if the clinically valid ones get sparse. Second, clinically invalid rules can be flagged during interpretation and turned off immediately or reviewed periodically.

Our performance analysis shows that roughly 30% of clinically valid rules are retrieved by the classifiers (e.g., RF’s recall on Mandatory is 0.322, Table 4). This rate is rather low, but further research is required to assess its impact on the clinical utility of the rule set. As we saw in the error analysis, the majority of false negative rule instances are never violated in the report corpus, which spans more than 10 years of echocardiogram service, and one can thus reasonably argue that their clinical utility is limited.

Limitations

Due to a technical insufficiency, the classifiers had to be re-trained after manual review of their false positives. There was only a partial overlap between the reviewed rules instances and the final classifiers’ false positives.

Success of our approach is ultimately determined by the number of violations detected by automatically discovered rules, not by the mere number of discovered rules, which is driving the F-measure metric adopted in this paper.

The reporting corpus and the QA rule set originate from one single institution. We simulated unseen data by splitting the rule instances in a dev and test set, but further research is required to assess the extent to which our results generalize to unseen data from other institutions.
The ground truth was based on mutual exclusion rules derived from the QA rule set. The review of false positive rules showed that this rule set is incomplete: there are clinically valid rules that were not marked as such in the ground truth. Incompleteness of the ground truth has potentially impacted our results and likely in an adverse manner.

Future research

Potential steps for future research include classifier refinement and evaluation on unseen report sets. We intend to construct a hybrid classifier composed of a manually created top-level decision tree that has Support Vector Machines (SVMs) optimized for classification in each subspace defined by the tree’s leaves. The decision tree component encodes the high-level reasoning process of the classifiers, whereas the SVMs optimize the decision boundaries for the numerical features in the subspaces defined by O/E and WOR. Evaluation of the classifiers on report data from different institutes is key to assessing generalizability of our results. Furthermore, future implementations can be configured to discover positively correlated FC pairs. Such patterns can be leveraged to auto-suggest FCs based on FCs previously entered in the report, which could save time and reduce mouse clicks.

Conclusions

Based on our results, we conclude that clinical knowledge can be derived from a large corpus of structured echocardiogram reports based on co-occurrence statistics and semantic analysis using machine learning methods. Automatically discovered clinical knowledge items can be leveraged as QA rules that monitor quality of echocardiogram reports either retrospectively or as a part of the reporting workflow. Our work exemplifies how structured reporting content can be utilized for data mining and diagnostic imaging workflow enhancement.

Patient Engagement in Cancer Survivorship Care through mHealth: A Consumer-centered Review of Existing Mobile Applications

Yimin Geng, MS, MSLIS, Sahiti Myneni, PhD, MSE
School of Biomedical Informatics
The University of Texas Health Science Center at Houston, Houston, Texas, U.S.A

Abstract

With improvements in early detection and treatment, the number of cancer survivors has been on the rise. Studies suggest that cancer survivors do not often receive proper follow-up care despite existing guidelines. Patient engagement is key to healthy survivorship, and mHealth provides a viable platform to empower survivors with just-in-time personalized support. However, our understanding of existing mHealth solutions in cancer survivorship is limited. In this paper, we use Patient Engagement Framework to investigate existing apps to bridge this knowledge gap. App features are mapped to the framework components to determine the level of engagement facilitated. Ability to record treatment summaries has been found in five out of seven apps examined. While collaborative care and social engagement are found minimally, the majority of features (95%) are limited to information and way finding, e-tools, and interactive forms. Limitations of the existing apps and possible improvements to the framework are discussed.

Introduction and Background

“Cancer survivors” refer to those people who have been diagnosed with cancer and the people in their lives who are affected by their diagnosis, including family members, friends, and caregivers [1]. The number of cancer survivors continues to increase due to the aging and growth of the population and improvements in early detection and treatment. As of January 2014, it is estimated that there are 14.5 million cancer survivors in the United States. By January 1, 2024, that number will increase to nearly 19 million [2]. Unfortunately, the current U.S. health care system is failing to deliver the comprehensive and coordinated follow-up care cancer survivors need. As per the Institute of Medicine report in 2006, too many survivors are lost in transition once they complete the cancer treatment [3]. This population is at risk not only for cancer recurrence, but also for receiving inadequate risk-based and routine preventative health care. In response to this, the Institute of Medicine report in 2006 recommended that every cancer patient should receive an individualized survivorship care plan that includes guidelines for monitoring and maintaining their health to help improve the quality of care of survivors as they move beyond their cancer treatment [4]. The basic components of survivorship care plans (SCPs) include a personalized comprehensive care summary and follow-up plan. SCPs are intended to be a patient-centered communication tool to improve the quality of follow-up care for cancer survivors. Although many SCPs have been developed, the incorporation of these plans into processes of care coordination and the ability of SCPs in empowering patients to self-manage their care has been limited [5, 6].

Mobile health technologies play an important role in helping cancer patients to become active participants in their care. Given the ubiquity of mobile devices and the omnipresent wireless connectivity, mHealth solutions have the capability to provide just-in-time support that is both adaptive and targeted to user needs [7]. mHealth solutions can be used to generate and share patient-centered care planning, to manage late effects with cancer and its treatments, to promote lifestyle and behavioral changes, and to assist survivors with communication with health care providers. Several research projects have examined the utility of mobile tools in supporting breast cancer patients. Healthweaver Mobile project, [8] and My Journey Compass [9] afforded cancer patients the ability to engage with their health, their health providers and their support networks. Although mobile apps have the potential for helping cancer survivors to manage their care, our understanding of the current state of mHealth in cancer survivorship is limited in terms of their ability to empower cancer survivors to self-monitor their care plans and engage in healthy living.

The objectives of our study are threefold: (1) to understand the role of mHealth in the facilitation of patient engagement in cancer survivorship care, (2) to identify the strengths and shortcomings of the current mobile apps geared towards empowering cancer survivors in self-management of their care and overall well-being, (3) to examine the applicability of available engagement framework in the assessment of survivorship mobile apps. In this paper, we specifically employ the Patient Engagement Framework (PEF) to describe the engagement features facilitated by the existing mHealth apps for cancer survivors. In the next sections of the paper, we discuss in detail the various components of PEF, our evaluation methodology, and subsequent results and discussions.
Theoretical Rationale

The Patient Engagement Framework (PEF) is a model created to guide healthcare organizations in developing and strengthening their patient engagement strategies through the use of eHealth tools and resources. The framework was first introduced in November 2012 by the National eHealth Collaborative [10] after a yearlong effort by over 150 top experts in healthcare, technology and human behaviors. PEF can be used as a guidance to evaluate the functionality of cancer survivor survivorship apps that potentially facilitate the adoption of SCPs, patient engagement, self-management of cancer, healthy behavioral change, goal setting and reinforcement, peer support, and assist survivors with communication with health care providers. PEF consists of five phases that begin with providing information and progress toward more active partnering and engagement [11]. The five cumulative phases to engagement that make up the framework include “inform me,” “engage me,” “empower me,” “partner with me,” and “support my e-community.” Each phase is described below along with specific examples relevant to cancer survivors.

- **Inform me phase** is about providing basic information on how to find the facility, providers, and services and with various electronic patient education information sources.
- **Engage me phase** is about engaging patients through health and wellness apps to monitor their diet, weight, and exercise routine and track health data, patient self-entering their health records and data, sending appointment and medication reminders by text messaging.
- **Empower me phase** is about offering secure text messaging with providers and engaging in customized text reminders for daily care, health and symptom assessment.
- **Partner with me phase** is about monitoring patients and tracking patient’s health data remotely.
- **Support my e-Community phase** is about offering online e-community support forums for better information exchange between survivors.

In addition to the phases which determine the level of engagement, the framework has 14 different categories that can help facilitate the intended level of engagement. PEF categories across the five phases include 1) Information and Way-finding, 2) Analytics/Quality, 3) e-Tools, 4) e-Visits, 5) Forms: Printable, 6) Interactive Forms: Online, 7) Integrated Forms: EHR, 8) Patient-Specific Education, 9) Patient Access: Records, 10) Patient-Generated Data, 11) Care Team-Generated Data, 12) Interoperable Records, 13) Collaborative Care and 14) Community Support. Within each of these categories, sample elements were provided as part of the framework to guide the system development process. Please see Figure 1 for detailed information regarding the various components (Phase, Category, and Sample Elements) associated with the PEF. As indicated in Figure 1, patient engagement level is embedded as a cumulative dimension of the framework, i.e. engagement categories in a given phase are specified in addition to the ones available in previous phase (e.g. Empower me engagement= Empower me+ Engage me).

In this paper, we used the basic version of the PEF to develop a rigorous evaluation method that enables the examination of the user engagement features facilitated by existing cancer survivorship applications on mobile platforms.

Methods

Study design

This study presents a descriptive assessment and review of the cancer survivorship applications available from the mobile app stores. Two researchers assessed each of the selected apps using PEF independently to determine phases and features of patient engagement. The features of each app were mapped to these 14 categories to assess the level of patient engagement facilitated by the apps. The app features mapped to a particular PEF category were scored based on the phase of patient engagement: 1 point for a feature with inform me phase, 2 points for a feature with engage me phase, 3 points for a feature with empower me phase, 4 points for a feature with partner with me phase and 5 points for a feature with support my e-community phase. The total PEF score for each app was computed by adding up the points assigned to all features embedded in that app.

Selecting Apps for Review

We searched Apple Store, iTunes, Google Play, Nokia Store, BlackBerry App World and Windows Phone for current available mobile applications using the keywords “cancer survivors”, “cancer survivorship”, “survivor care” and “care plan” in November 2014. Initial search returned 15 related cancer survivorship applications. The inclusion criteria defined for this study are 1) target users are cancer survivors who have completed cancer treatment, and 2) content include either follow-up care plan or late effect management or healthy lifestyle or stress management. Of the 15 apps
retrieved using the search terms, seven applications were identified to meet the criteria. We examined the features of these seven apps to categorize their features using PEF as discussed in the study design. After completing mapping of the applications to PEF, two researchers assessed their reliability of agreement using Cohen’s Kappa measure. The coders had a reliability of $\kappa = .76$, indicating strong consistency and reliability in the coding process.

![Evaluation methodology using Patient Engagement Framework for mHealth apps in Cancer Survivorship](image)

**Figure 1.** Evaluation methodology using Patient Engagement Framework for mHealth apps in Cancer Survivorship

### Results and Discussion

Table 1 shows the general descriptions for the apps. All these seven apps are designed for cancer survivors who have completed their cancer treatment. Among the seven apps, five apps have comprehensive treatment summary or follow up care plans. Three apps provide support infrastructure for late effects management, while two apps were designed for childhood cancer survivors. One application provides a networking platform to connect cancer survivors and caregivers to a network of healthcare providers specializing in cancer survivorship. Of the seven apps, two were developed by hospital entities, one by a research university and four by non-profit organizations with or without university collaborations. A detailed description for each of the apps is provided in Table 1.

We observed 42 features in total for all of these seven applications. On average, there are six features for each app. We aligned all the observed features to the 14 categories within PEF. Overall, the 42 app features mapped to seven of the 14 PEF categories described in the previous sections. Majority of the apps (five out of seven) had the ability to record personal health information and treatment summaries. A detailed distribution of the app features across the engagement categories can be seen in Figure 2.
Table 1. General information about mobile apps for cancer survivors evaluated in this study

<table>
<thead>
<tr>
<th>Apps</th>
<th>Developer</th>
<th>General description</th>
</tr>
</thead>
<tbody>
<tr>
<td>App 1</td>
<td>University Hospital</td>
<td>This survivor app supports patients during survivorship phase. This app includes information on recovering and remaining healthy after cancer treatment. It has interactive tools to keep track of questions to ask doctors. It provides individualized end-of-treatment summary and survivorship care plans. Unique feature is only available to testicular cancer survivors.</td>
</tr>
<tr>
<td>App 2</td>
<td>Non-profit organization</td>
<td>This app connects cancer survivors and caregivers to a network of healthcare providers specializing in cancer survivorship. This app can help people in taking charge of their personal and financial health by providing education and information regarding survivorship care plan and healthy lifestyle.</td>
</tr>
<tr>
<td>App 3</td>
<td>University</td>
<td>This app is for survivors who have completed their treatment for breast cancer. The app enables users to record treatment summary and then email right from their phone to any provider that they might see in the future.</td>
</tr>
<tr>
<td>App 4</td>
<td>Collaboration of Non-profit organization and university research group</td>
<td>This app will help cancer survivors create Survivorship Care Plan. It allows cancer survivors to initiate their own SCP and then complete with the help of provider. The survivor and her/his healthcare team can use this app to coordinate the follow-up care and manage ongoing symptoms.</td>
</tr>
<tr>
<td>App 5</td>
<td>Non-profit organization</td>
<td>This app is to help survivors understand and minimize the side effects of cancer and cancer treatment. It offers nutrition guidance and practical tips to help survivors feel better, maintain their strength, and speed their recovery from common cancer side effects.</td>
</tr>
<tr>
<td>App 6</td>
<td>Collaboration of Non-profit organization and university research group</td>
<td>This app is designed for Adolescent and Young Adult (AYA) cancer survivors (ages 15-39). It is an interactive app to assess health habits and general sense of well-being. It offers personalized tips for being more active, eating better and living a healthier life.</td>
</tr>
<tr>
<td>App 7</td>
<td>Hospital</td>
<td>This app offers childhood cancer survivors the resources, tips, and tools necessary to help minimize potential problems, or late effects, caused by childhood cancer and/or its treatments.</td>
</tr>
</tbody>
</table>

Results indicated that the survivorship app features were mapped to only half of the PEF engagement categories while there are no features to map to the other half. The PEF categories that have features mapped to include: Information and Way-finding, e-Tools, Interactive Forms, Patient-Specific Education, Patient-Generated Data, Collaborative Care and Community Support. These categories support several functions such as:

1) Providing basic information on how to find the facility, providers, and services and with various electronic patient education information sources and tools for care plan creation;
2) Facilitating patients to create care plan, self-enter their patient medical history and manage their medical documents;
3) Tracking health data and lifestyle (diet, weight, and exercise routine); sending appointment and medication reminders by text messaging;
4) Sending text reminders for daily care, health and symptom assessment;
5) Offering social media to potentially support better information exchange among survivors; and
6) Providing support environment through online communities, where cancer survivors can engage in peer-to-peer communication.

Such features can enable users to access, and organize health-related information, while promoting patient-provider communication. Through reminder capabilities, the apps allow patients to comply with care follow-up services as recommended in the survivorship care plans. Online social media and forum capabilities allow users to share their progress with peers and family, while getting exposed to a variety of social support mechanisms [12].
The examination of the app features using PEF (see Figure 3) indicated that the current mHealth solutions for cancer survivors had 38% of features at “inform me” level (16 out of 42 features) and 36% at “engage me” (15 out of 42 features), 21% at “empower me” level. There are fewer features at more active phases, 2.5% at “partner with me” level and 2.5% at “support my e-community” (1 out of 42 features). As shown in Table 2, Patient Engagement Score (PES) was computed by aligning each of the features with the engagement phases described in the PEF. The scores ranged from 7 to 17, with majority of the features facilitating lower levels of engagement. Results indicate that App 5 was rated with the highest PES and seconded by App 1. Interestingly, App 5 is the only app that was rated five stars by users who downloaded the apps in both iTunes/App store and Google Play store.

</table>

In Table 3, we attempted to depict how the apps performed in each of the PEF categories in terms of the engagement level they facilitated. The heat map highlights the sophistication in terms of the apps’ ability to engage patients with a specific information kind. For Information and Way-finding, most app features are at the “inform me” phase, while for e-tools, app features are at “engage me” and “empower me” phase. For Patient-specific education, app features reached “engage me” phase. There are features for patient-generated data at “empower me” phase, while features for collaborative care are at “partner with me” phase. None of the apps have features such as quality and safety reports on providers and healthcare organizations, or patient-specific quality indications and analytics promoting empowerment and engagement. Of the top three apps that received higher PES score, two apps were developed by a hospital entity. Given that the original objective of the PEF is to enable the health institutions engage their patients, the results are intuitive. Overall, results indicated that majority of the apps are still in initial phases of facilitating patient engagement. There is room to improve in several areas of care facilitation and patient empowerment. Two important areas include (a) harnessing social technologies to gather care information and facilitate peer-to-peer connections that offer emotional and informational support when needed, and (b) development and deployment of consumer-centered care coordination tools that facilitate efficient care transition, family involvement, and self-management of care information. Collaborative access to electronic health records, patient-centered analytics demonstrating physician feedback on patients’ self-management of care plan are other key areas that warrant specific focus to attain high levels of patient engagement.

**Supplements to the Patient Engagement Framework**

Integrating behavior change theories is vital to engage users in self-management of health. For example, Engaging Consumers in Health with Health Care (ECHC) framework incorporates traditional theories of behavior change in a simplified manner by considering individuals, their social and environmental interactions [13]. However, researchers question the validity of traditional theories in digital health era [14]. Existing behavior change theories may be insufficient to inform mobile intervention development, given the novelty and distinctions in the interaction and connectivity paradigm associated with mobile platforms. It is important to understand the nature of health-related behaviors and evolution of user needs in the context of web-based and mobile platforms through development of multi-disciplinary analytics that offer both depth and scale [15-17]. Based on the lessons learned from this study, we suggest the integration of behavior change strategies [18] using technology development frameworks [19,20] that consider the role of human cognition and social-technical factors surrounding users’ health-related behaviors. Such theory-driven, ecologically-modeled mobile health technologies can form the crux of user-inclusive care management models. Subsequently, the resulting mobile ecosystem can presumably engage the “digital consumer” in self-management of health conditions (e.g. cancer survivorship). In addition, existing patient and user engagement frameworks are limited to the operationalization of engagement attributes as technology features. However, to fully analyze and realize the benefits of such technology accessories, the current realm of engagement models should be expanded to provide standardized assessment criteria that facilitate the evaluation of health outcomes. Such an integrated framework results in mHealth solutions that can potentially promote cancer survivor engagement in their own care, while providing an account of the ways in which such increased engagement may result in superior health outcomes.

**Limitations and Future Work**

The study described in the paper is not without limitations. The search strategy employed limited our focus to the official application stores. A more comprehensive search such as searching scientific literature or app clearinghouse websites [21] may retrieve more apps for cancer survivorship care. This study only examined the features of the cancer survivorship care apps in terms of the HIMSS Patient Engagement Framework. Given the complexity of cancer survivorship care, the framework may not be detailed enough to cover all of mobile features for survivorship care. For
example, based on this definition for “Patient engagement”, that is, “patients, families... and health professionals working in active partnership at various levels across the health care system... to improve health and health care...”[22], the family-centered nature of cancer survivorship has not been captured by the framework. Furthermore, the framework used in the study is aimed at health institutions to develop solutions that are patient-engaging. However, the framework is not completely suitable to identify engagement features for technology solutions that solely involve health consumers. In this paper, we did not intend to evaluate the apps for their effectiveness and performance. The patient engagement score determined in the study does not account for the impact on patient health care outcomes. For example, a feature at Support my e-community level may not necessarily have five times the impact on health outcome than a feature at inform me patient engagement level and more features for a single PEF elements may not necessarily indicate superior engagement levels. Further work on the evaluation of the usefulness and effectiveness of the mobile apps in improving health outcomes are needed. In addition, we have limited our review to mobile platforms, and therefore our paper does not provide an exhaustive evaluation of all the survivorship application that may be available only on web platforms. This study is an attempt to use Patient Engagement framework to evaluate the cancer survivorship mobile app features to understand the ways in which technology facilitates user engagement in self-management of care. PEF is created for healthcare organizations to develop and strengthen their patient engagement strategies. However, the cancer survivorship apps evaluated in this study were developed by a variety of organizations to help survivors engage in their own care. In addition, the Patient Engagement framework provides an account of technology-related functionalities alone, however, user engagement can be facilitated in several dimensions through use of novel inter- and intra-personal interactions distributed among the user, the app, and the environment in which the user interacts with the app [23]. Therefore, sole reliance on the Patient Engagement Framework for the design of consumer-facing mobile apps may not result in the elevation of engagement levels in all these aspects. Broader evaluation frameworks that provide us deeper understanding of the utility and implementation of traditional behavior change strategies, contemporary theories of user interactions are needed for the design and evaluation of the mobile applications that potentially promote cancer survivor engagement in their own care.

Conclusions

Mobile technology holds promise in promoting communication between cancer survivors and healthcare providers, patient engagement, and care coordination [26,27]. However, there are few apps that are targeted to cancer survivors when compared to the growing market of mobile health applications. The development and adoption of mobile apps for cancer survivorship care is still in its infancy. Using Patient Engagement Framework, we have discovered that there is a lot of room for improvement in several areas, specifically, integration of data analytics and dashboard features that establish two-way communication among providers and patients, facilitation of peer-to-peer communication through online community infrastructure inbuilt within the app, and provision of mobile access to patients’ electronic health records. Majority of the already operationalized features (95%) are at beginning or intermediate levels of patient engagement (inform me, engagement me and empower me) in terms of documentation of treatment summary and implementation of cancer survivorship care plan. Most active patient engagement features such as facilitating collaborative care and online community integration need to further evolve. Furthermore, we need to develop a new health consumer engagement model that solely aids in the incorporation of user engagement attributes that capture health-related socio-behavioral constructs, and facilitate outcome-based technology modeling and evaluation. Such an integrated approach will afford a design, development, and evaluation process that results in mobile apps that are consumer-centered, user-engaging, and theoretically-aligned.

Abstract
An association between periodontal disease and rheumatoid arthritis is believed to exist. Most investigations into a possible relationship have been case-control studies with relatively low sample sizes. The advent of very large clinical repositories has created new opportunities for data-driven research. We conducted a retrospective cohort study to measure the association between periodontal disease and rheumatoid arthritis in a population of 25 million patients. We demonstrated that subjects with periodontal disease were roughly 1.4 times more likely to have rheumatoid arthritis. These results compare favorably with those of previous studies on smaller cohorts. Additional work is needed to identify the mechanisms behind this association and to determine if aggressive treatment of periodontal disease can alter the course of rheumatoid arthritis.

Introduction
Rheumatoid arthritis is an autoimmune disease characterized by chronic and systemic inflammatory changes. The specific disease mechanism is not fully understood, but it is believed to involve a combination of genetic and environmental factors. It can involve different parts of the body but principally attacks the joints. It is a disabling and painful condition that can lead to substantial loss of function and mobility. Rheumatoid arthritis has a significant impact on society and affects roughly 1% of adults in the developed world. The prevalence of rheumatoid arthritis increases with age, and the disease is roughly three times more common among women. The treatment includes both medical and non-pharmacologic therapies to control inflammation and prevent joint damage.

Periodontal disease is a chronic inflammatory condition of the periodontal tissues. It is one of the most common oral diseases, affecting roughly half of all adults over age 30. The disease is the result of an opportunistic infection by specific microorganisms in the oral cavity. This leads to a destructive inflammatory process, and ultimately to bone and tooth loss, as well as other sequelae. Good oral hygiene and regular professional cleanings are used to prevent and treat periodontal disease. More extensive interventions can be used to treat refractory disease.

The creation of very large clinical repositories has opened new opportunities for data-driven research. One such repository is the national patient database from the Veterans Health Administration (VA), which is available through the VA Informatics and Computing Infrastructure. For each patient, structured information is available, including demographics, diagnostic codes, outpatient visits, hospital admissions, patient orders, vital signs, laboratory testing, inpatient and outpatient pharmacy data, clinical consults, immunizations, mental health screening, associated physicians, and payment information. The repository also includes unstructured and semi-structured information in the form of progress notes, radiology reports, procedure reports, images, and other clinical narratives.

The VA dataset is one of the largest clinical repositories available, providing detailed patient information for approximately 25 million patients who received care at 152 medical centers and more than 800 outpatient clinics across the United States over the past 15 years. The repository includes more than 4 billion progress notes, 2 billion procedure and imaging reports, 1.6 billion medication fills, and 1.5 billion diagnoses. These data will eventually be combined with genomic data from the Million Veteran Program, which when complete, will be one of the largest genomic databases in the world. The VA data set is one of the best, biggest, and most detailed data repositories for studying disease with unprecedented statistical power.

A number of research projects have explored the relationship between periodontal disease and rheumatoid arthritis. The exact nature of this relationship has yet to be defined, and most studies to date have been performed on relatively small patient cohorts. The two conditions might have a non-causal relationship through a common mechanism, due to shared genetic and environmental risk factors. Alternatively, they could have a causal
relationship, with one condition influencing the course of the other. In this paper, we present the results of our inquiries using the VA repository to study the association between periodontal disease and rheumatoid arthritis.

**Methods**

We conducted a retrospective cohort study to measure the association between periodontal disease and rheumatoid arthritis using a very large clinical repository. This work was supported through a grant from The Arthritis Foundation. Our research was also supported with resources and facilities from the Baltimore VA Medical Center, the Veterans Affairs Informatics and Computing Infrastructure, and the Department of Emergency Medicine at the University of Maryland School of Medicine. Regulatory approval for this work was obtained from the University of Maryland School of Medicine, the Baltimore VA Medical Center, and the Veterans Affairs Informatics and Computing Infrastructure.

The VA repository is housed by the Veterans Affairs Informatics and Computing Infrastructure. A secure workspace is provided through a Microsoft Windows-based remote desktop connection within the national VA network. The data are store in a Microsoft SQL Server database. Other applications available in the secure workspace include Excel, MATLAB, Protégé Knowtator, SAS, SPSS, and R.

The VA repository contains data for all patients who received care from 1999 through the present day. As outlined in Figure 1, we limited our search to the years 1999 through 2012. Our dental cohort consisted of all people in the 25-million-patient VA repository who had at least 4 visits in one of the VA dental clinics for any dental issue. We also limited our cohort to people who had enough clinical encounters to have accumulated at least 100 International Classification of Disease (ICD) codes. This focus ensured that enough dental and other clinical information was present to minimize the possibility of bias due to incomplete data. Within this cohort, we identified patients with periodontal disease as those who had at least 4 dental encounters for the condition, indicated as ICD code 523.x.

Also within the dental cohort, we identified people with rheumatoid arthritis based on those who had the appropriate ICD code (714.0, 714.1, 714.2, 714.4, 714.8, or 714.9) and who had at least one positive serologic test (rheumatoid factor or anti-CCP). Our approach to the diagnosis of rheumatoid arthritis was taken from previous work to verify the accuracy of ICD codes. That earlier work concluded that, within the VA population, ICD code 714 is a sensitive screening tool for identifying patients with rheumatoid arthritis. Combined with a positive serology result, it achieved 88% sensitivity and 91% specificity, and had a 93% positive predictive value.

**Figure 1. Identification of the dental cohort.**

![Figure 1](image)
We excluded people with missing or incomplete information regarding date of birth, gender, location, or clinical encounters. We calculated odds ratios using 2x2 tables to measure the association between periodontal disease and rheumatoid arthritis. We also calculated 95% confidence intervals to estimate the precision of each odds ratio.

**Results**

Half of the patients in the dental cohort had periodontal disease (433,674 out of 865,256). A total of 21,442 patients in the dental cohort (2.5%) had rheumatoid arthritis. Patient demographics are presented in Table 1.

As shown in Table 2, the odds ratio between periodontal disease and rheumatoid arthritis is 1.42 (95% CI, 1.37 – 1.46). This finding holds for men and women, and for those above and below the median age of the cohort. It also holds for Caucasians, African Americans, and Hispanics. It did not hold for Asians, who represented only 0.7% of the cohort.

Discussion

A growing corpus of evidence points to an association between periodontal disease and rheumatoid arthritis. Most previous reports were based on case-control studies and meta-analyses, all of which had relatively low sample sizes. Our approach was the first large-population study to confirm this association, demonstrating that subjects in our cohort with periodontal disease were roughly 1.4 times more likely to have rheumatoid arthritis compared to other dental patients.

Several hypotheses have been proposed to explain this association. One suggests that chronic inflammation from periodontal disease can trigger systemic factors, which can induce rheumatoid arthritis. Another hypothesis suggests that rheumatoid arthritis is triggered through an autoimmune response to periodontal bacterial byproducts.
A third hypothesis is based on the existence of a shared pathway in the development of both periodontal disease and rheumatoid arthritis15.

Our approach has a number of notable limitations. We identified patients with periodontal disease by ICD codes, and not by chart review or by a direct observation of clinical findings. We attempted to mitigate ICD code accuracy11,16 by requiring at least 4 dental clinical visits for periodontal disease. Other studies were based on patient-reported information17, physician interviews, or review of medical records18, which would be very expensive to perform with the very large VA repository. In future work, we plan to refine our patient cohort by applying text analytics for information extraction from electronic health records, as we and other investigators have done on past efforts19,20,21.

Our definition of rheumatoid arthritis, based on previously reported work11, was shown to be very sensitive in the VA population. However, it was not based on the gold standard for the diagnosis of rheumatoid arthritis diagnosis using clinical and radiographic findings. Another limitation was the exclusion of individuals with negative serologic test results, frequently associated with early rheumatoid arthritis or diagnosis at advanced age22. A recent meta-analysis of reports related to the diagnosis of rheumatoid arthritis documented that anti-CCP antibody or rheumatoid factor positivity had only 78% sensitivity (CI, 76%–80%)23,24. If we had relied on that definition in our study, we would have missed a substantial number of patients who actually met our criteria.

Finally, our research was limited to the national VA repository. About 90% of the patients whose records are stored in that database are male and about 60% are Caucasian. In addition, our analysis was limited to U.S. veterans who received both medical and dental care through the Veterans Health Administration.

Additional research is needed to explore the significance of this association and of any temporal significance between the two conditions. These investigations could ask whether the treatment of periodontal disease in people at risk for rheumatoid arthritis (e.g., females, older people, those with specific human leukocyte antigen genes) can prevent rheumatoid arthritis. Research is also needed to study whether the treatment of periodontal disease in people with rheumatoid arthritis can relieve its manifestations (fatigue, joint pain, morning stiffness). Finally, research is needed to identify ways to apply big data analytics to large clinical repositories to elucidate more about this association, and to explore temporal correlations between rheumatoid arthritis and periodontal disease.

**Conclusion**

We conducted a retrospective cohort study to measure the association between periodontal disease and rheumatoid arthritis. This was the first such study to employ a very large clinical repository. We demonstrated that patients with periodontal disease were roughly 1.4 times more likely to have rheumatoid arthritis compared to other dental patients. These results compare favorably with previous studies on smaller cohorts. Additional work is needed to identify the mechanisms behind this association and to determine if aggressive treatment of periodontal disease can alter the course of rheumatoid arthritis.

Simulation-based Evaluation of the Generalizability Index for Study Traits

Abstract

The Generalizability Index for Study Traits (GIST) has been proposed recently for assessing the population representativeness of a set of related clinical trials using eligibility features (e.g., age or BMI), one each time. However, GIST has not yet been evaluated. To bridge this knowledge gap, this paper reports a simulation-based validation study for GIST. Using the National Health and Nutrition Examination Survey (NHANES) data, we demonstrated the effectiveness of GIST at quantifying the population representativeness of a set of related trials that differ in disease domains, study phases, sponsor types, and study designs, respectively. We also showed that among seven example medical conditions, the GIST of age increases from Phase I trials to Phase III trials in the seven disease domains and is the lowest in asthma trials. We concluded that GIST correlates with simulation-based generalizability results and is a valid metric for quantifying population representativeness of related clinical trials.

Introduction

Randomized controlled trials (RCTs) have been widely regarded as the gold standard in medical research [1]. To ensure the internal validity of a clinical study when testing the efficacy of a treatment, clinical trialists often use restrictive eligibility criteria for participant selection [2]. However, unjustified exclusion criteria may unfairly deprive the opportunity of patients to benefit from the trial, and more importantly, compromise the generalizability of its results to the real-world patient population [3]. Consequently, many FDA-approved medications were later withdrawn from the market due to safety problems that had not been detected in pre-marketing clinical trials but only apparent after exposing the medications to a broader patient population [4, 5].

To assess the population representativeness of clinical trials, researchers may compare the study population of a single trial with a convenience sample of the real-world patient population [6, 7]. Most of the generalizability assessment studies identified in the literature focus on posteriori generalizability and thus can be conducted only after the conclusion and publication of a trial. In contrast, priori generalizability, whose focus is on the eligibility of participants, can be assessed during trial design. Posteriori generalizability is almost always lower than priori generalizability because eligibility criteria always subsume the characteristics of study participants [8]. In addition, our previous study found that many trials, especially those on the same medical condition, often use similar or identical eligibility criteria, indicating that the generalizability issue may not be only at the individual trial level, but also across a whole body of trials for a clinical domain at the research community level [9].

To facilitate a priori generalizability assessment, a method was recently published for systematically assessing the population representativeness of a set of related trials. This method compares the aggregate target populations of all the trials under consideration, which characterize the patients who can be enrolled in these trials according to the inclusion and exclusion criteria, with the “real-world” patient population from electronic health records (EHRs) [10]. The Generalizability Index for Study Traits (GIST) was initially introduced along with this method [10]. This paper reports the initial study evaluating the validity and effectiveness of GIST.

Background

GIST is a mathematical function for quantifying the collective population representativeness of a set of clinical trials with reference to the real-world patient population measured by a single quantitative eligibility feature. There are three parameters in the GIST function: i.e., the real-world patient population (PP), the target population (TP) of a trial set, and an eligibility feature (not shown in the formula for brevity). The GIST metric is conceptually similar to Weisberg et al.’s model of patient selection bias in a trial using a counterfactual framework, which takes into account the proportion of patients with an adverse event incidence and the probability of such patients being selected by a trial [11]. GIST score ranges between 0 and 1, with 1 being most generalizable and 0 being least generalizable. It first discretizes the value range of an eligibility feature into consecutive non-overlapping value intervals and then sums the percentage of studies that recruit patients in each interval multiplied by the percentage of patients in the real-world population observed in that interval across all the intervals. GIST can quantify the representativeness of the target population (TP) for the patient population (PP) with respect to an eligibility feature such as age. The mathematical formula of GIST is:

\[
\text{GIST} = \sum_{i=1}^{n} p_i \times g_i
\]

where \(p_i\) is the proportion of patients in the \(i^{th}\) interval, \(g_i\) is the percentage of studies that recruit patients in that interval, and \(n\) is the number of intervals.
Clinical trial target population (P0): the patients being sought as defined in the clinical trial eligibility criteria.

“Real-world” patient population (P1): the patients to whom the results of clinical trials are intended to be applied. We can only approximate its definition given available data resources about these patients.

Weighted “real-world” patient population (P2): the patients sampled from the “real-world” patient population based on the percentage of trials considering these patients for inclusion.

Clinical trial study population (P3): the study participants who are actually enrolled in a clinical trial. Compared to P1 and P2, the study population P3 maximally (if not perfectly) reflects the target population (P0) because all enrolled study subjects should meet the eligibility criteria that define the target population.
