To harness these benefits of CDS-based QM, we have previously implemented a prototype CDS-QM framework in which a standards-based CDS Web service is leveraged across a population to enable QM. This earlier prototype was able to successfully automate the evaluation of an inpatient quality measure (SCIP-VTE-2) with a recall of 100% and a precision of 96%.

Need for optimizing execution performance. Despite the benefits of CDS-based QM, earlier research has identified execution performance as a critical challenge to operationally deploying such an approach at scale. For example,
our earlier prototype of this approach\(^6\) required approximately 5 seconds to process a measure group for a single patient. Similarly, the CDS Consortium has previously reported that a similar CDS Web service approach to patient evaluation required a similar amount of time to process.\(^7\) While reasonable for QMs with limited population sizes, such as an inpatient quality measure which may only apply to several hundred patients at any given time, this approach is not scalable for QMs that apply to much larger patient populations, such as outpatient quality measures related to preventive care. For example, at 5 seconds per patient per measure group, processing 22 outpatient quality measure groups for 370,000 patients (e.g., to assess all patients seen within the past year at our health care system) would take over a year to process. Execution time is also an important consideration for real-time CDS as well as population-based CDS involving large numbers of patients.

At University of Utah Health Care (UUHC), our objective was to implement a CDS-QM framework for enterprise deployment, including for outpatient quality measures. To enable such enterprise use of this promising approach to QM, we needed to be able to evaluate a large number of QMs for very large patient populations in less than 24 hours (i.e. within one business day). This manuscript describes the performance optimizations that were implemented in order to meet this business need, such that the processing time was decreased approximately three orders of magnitude, from approximately 5 seconds per measure group per patient to 2 milliseconds per measure group per patient. By describing these performance optimizations and their relative impact, we seek to facilitate others’ operational use of a CDS-QM approach for large-scale quality measurement and population health management.

**Methods**

**Study Context**

This study was conducted to meet operational quality measurement needs at University of Utah Health Care (UUHC), which serves as the Intermountain West’s only academic healthcare system and includes four hospitals, 10 community clinics, over 10,000 employees, and over 1,200 physicians. Approximately 370,000 patients are seen at UUHC in any given year. This study was approved by the University of Utah IRB (protocol # 00080838).

The CDS-QM framework was initially applied at UUHC for calculating inpatient quality measures such as the Patient Safety Indicators (PSI) from the Agency for Healthcare Research & Quality (AHRQ) and Surgical Care Improvement Project (SCIP) measures from the Joint Commission. Because only several hundred hospitalized patients would be relevant for these measures at any given time, execution performance did not need to be optimized for evaluating these measures. The initial CDS-QM framework developed for inpatient quality measurement purposes represents the Phase I framework described below.

Subsequently, there was an institutional need to evaluate Healthcare Effectiveness Data and Information Set (HEDIS) outpatient quality measures from the National Committee for Quality Assurance. HEDIS measures are used by more than 90 percent of U.S. health insurers as a measure of quality and encompass measures such as the frequency of prenatal care visits compared to established standards and the degree of glycemic control in patients with diabetes mellitus.\(^8\) HEDIS measures are calculated based on a combination of administrative/billing data and EHR data such as laboratory results, vital signs, immunization records, and procedure records.

At UUHC, the HEDIS measures had been calculated manually, in part due to the highly complex nature of many of the measures. For example, to calculate the number of prenatal visits that occurred in the first trimester of pregnancy, HEDIS defines 17 distinct patterns of eligibility. For this initiative, 22 measure groups (e.g., comprehensive diabetes care) encompassing 78 individual measures (e.g., % of members 18-75 years of age who had proper Hemoglobin A1c testing) were prioritized for automation.

The initial focus for the CDS-QM effort was to evaluate HEDIS measures for approximately 20,000 patients whom our commercial health plans considered to be primarily managed by UUHC clinicians. The platform developed to handle this scope of evaluation is reflected in the Phase II CDS-QM framework below.

Subsequently, the University of Utah Medical Group decided to base clinician compensation in part on their performance on HEDIS quality measures. This increased the applicable patient population to the approximately 370,000 patients seen at UUHC at least once within a one year timeframe. The platform developed to handle this
scope of evaluation represents the Phase III CDS-QM framework below. In all cases, the business need was for the evaluation of all HEDIS quality measures to be completed for all relevant patients within one business day.

**Required Computational Tasks**

The CDS-QM framework was required to perform three primary computational tasks, each of which served as targets for performance optimization. The first task was data collection, in which patient data were retrieved from the data warehouse. In all phases, query parameters were set to restrict the data to those relevant for the required quality measure evaluations. The second task was data transformation, in which the collected data were converted into the Health Level 7 (HL7) Virtual Medical Record (vMR) data format, which is a standard data model for CDS. Finally, the third task was data evaluation and storage, in which the OpenCDS decision support Web service generates quality measurement assessments based on the vMR data, which are in turn stored in the data warehouse for analysis and reporting.

**Qualitative Description of CDS-QM Framework by Phase**

As described above, the business need for the CDS-QM framework evolved over three phases: a framework needed for evaluations of less than 1,000 patients at a time, evaluations of approximately 20,000 patients at a time, and evaluations of approximately 370,000 patients at a time. Accordingly, the framework was adapted in a phased approach. Each of these phases is described with respect to its approach to the three computational tasks.

**Identification of Challenges and Solutions**

The challenges encountered in optimizing execution performance are described, along with optimization solutions devised. Many different optimization approaches were implemented, but only those with significant impact are discussed here.

**Scalability Analysis for Phase III Framework**

For the final, phase III CDS-QM framework, we measured the time required for evaluating 22 HEDIS quality measure groups for increasingly large patient populations. The 22 HEDIS quality measure groups included 78 individual quality measurements. These analyses were conducted for 1 patient, 1,000 patients, 20,000 patients, and 370,000 patients.

**Results**

**Qualitative Description of CDS-QM Framework by Phase**

The overall CDS-QM process during phases I, II, and III are summarized in Figures 1, 2, and 3 respectively and described below. Moreover, the Table summarizes the optimization challenges, corresponding solutions, and impact for phases II and III. These challenges, solutions, and impact are also discussed in the framework descriptions below.

**Phase I CDS-QM Framework**

*Overall Approach and Performance*

In this phase, all three computational tasks were conducted on a patient-by-patient basis in sequence. The CDS-QM framework averaged approximately 5 seconds per patient per measure group, with almost all of the time required for data collection.
In this phase, data were collected patient-by-patient, encounter-by-encounter using an integration engine called Mirth Connect. The integration engine directly queried the data warehouse and provided a scripting-based platform for accessing and transforming the patient data. An initial query identified the patient cohort to be analyzed. Then, for each identified patient, all subsequent tasks were conducted in sequence on a patient-by-patient basis. With regard to patient data collection, these patient-specific tasks included retrieval of demographic data and retrieval of relevant encounters. Then, for each relevant encounter, relevant associated data, such as for procedures, lab results, diagnoses, medications, and vital signs were retrieved in a sequential, repeating manner. This strategy produced a nested looping process where every nested query was run once for each patient and for each encounter. The collected data were held in volatile memory.

After all queries were completed for an individual patient, the collected data were transformed into HL7 vMR objects. Data transformation occurred sequentially, one patient at a time.

The data were sent using an HL7 Decision Support Service-compliant interface, specifying which quality measures should be used to process the patient vMR. The results for each specified quality measure were returned to and parsed by the integration engine and written back to the data warehouse. This was also done sequentially, one patient after the other.

**Phase II CDS-QM Framework**

Challenges from Previous Phase, Overview of Solutions Devised, and Performance

There were two main challenges from the Phase I framework. First, data retrieval was a clear rate limiting step, such that the approach clearly could not scale to even tens of thousands of patients. A second challenge was that volatile memory limitations of the computing hardware prevented the simultaneous processing of a large number of patients.

To address these challenges, we altered the database queries to obtain data for the entire cohort of interest once, instead of for each patient sequentially. We also parallelized data queries and stored vMR fragments (e.g., vMR
procedure fragments, vMR medication fragments) on disk to allow this parallelization within volatile memory constraints. This phase of the CDS-QM framework allowed approximately 20,000 patients to be evaluated for 22 HEDIS quality measure groups in approximately 8 hours, or an average of about 70 milliseconds per patient per measure group.

**Phase II, Task 1: Patient Data Collection**

The step for collecting patient data was first optimized by modifying and optimizing the query strategy to retrieve data for all patients in the measurement cohort rather than for a single patient per query. As long as source tables were properly indexed, most queries for the population data were nearly as fast as the same queries for a single patient. As a result, significant performance gains were realized after implementing this population-based query approach.

The result sets for these queries were large, so they could not be stored in volatile memory and hence were cached into a temporary schema. The cached results were later processed using a result set cursor, so that only a small portion of the result set was brought into volatile memory at any given time. We also found that our queries could run independently of each other, and hence modified our query strategy to include running the queries in parallel.

**Phase II, Task 2: Data Transformation**

The data transformation step was integrated into the data collection process. Fragments of the vMR were created for each relevant data element type (e.g., procedures, medications, lab results), and these fragments were stored in the temporary data cache as character large objects (CLOBs)\(^2\). The vMR fragments were then compiled with the demographic and encounter data from the temporary cache and transformed into individual patient vMRs.

**Phase II, Task 3: Data Evaluation and Storage**

Directly following vMR creation, each vMR was sent to the CDS Web service for processing. This step remained unmodified from the Phase 1 implementation.

**Phase III CDS-QM Framework**

**Challenges from Previous Phase, Overview of Solutions Devised, and Performance**

There were two main challenges from the Phase II framework. First, storing the transformed vMR fragments on disk became rate-limiting, due to the relatively slow speed of writing CLOBs into the data warehouse and reading

---

1198
from it. Also, for very large runs (e.g., 370,000 patients), this approach could not scale to the amount of storage space available in the data warehouse for this project. A second challenge was the sequential nature of vMR creation and evaluation. Whereas data retrieval was the clear bottleneck in Phase I, data storage (caching) and evaluation became the dominant bottlenecks in Phase II.

To address these challenges, we first stored the raw patient data into a standardized staging schema. For example, instead of storing a vMR XML fragment for procedures as a CLOB, the source data points required to generate this vMR XML fragment were stored in an indexed table with non-CLOB data types such as integers and dates. As a second key solution, we parallelized the vMR creation using multi-threaded processing techniques and used multiple servers, each with a deployed instance of OpenCDS, for evaluation.

Beyond these infrastructure-level optimizations, we also sought to optimize the execution performance of OpenCDS itself. We added the ability to process the set of requested measure groups in parallel. We also improved the performance of multiple requests by scaling the performance by the number of CPU cores (processors) available on the system. This current phase of the CDS-QM framework allows approximately 370,000 patients to be evaluated for 22 HEDIS quality measure groups in less than 5 hours, or an average of about 2 milliseconds per patient per measure group. Of note, continuous validation of CDS-QM results was performed against a sample of manual chart audit results. Systematic improvement based on this continuous validation process has resulted in a system with validity demonstrated to be equivalent to, and in some cases better than, manual QM analysis.

Figure 3. Phase III CDS-QM Process.

Phase III, Task 1: Patient Data Collection
Data collection continued to be conducted using population-based, parallel queries. However, instead of storing the collected data as pre-transformed vMR fragments in CLOBs, the source data elements were stored in their native data formats in a staging database schema.
Phase III, Task 2: Data Transformation

Staging the raw data, as opposed to the vMR fragments, facilitated the decoupling of the transformation task from the data collection task. Another subsystem, hereafter referred to as MeasureRunner, was developed to transform the data from the staging schema to individual patient vMRs. This process allowed the parallel creation of multiple patient vMRs, which in turn enabled the maximal use of available system resources.

Phase III, Task 3: Data Evaluation and Storage

MeasureRunner enabled the parallelization and batch evaluation of vMRs using the OpenCDS decision support service. Multiple instances of the decision support service were deployed to allow parallel processing. Responses were parsed and stored asynchronously as they were returned by the decision support service instances.

Challenges and Solutions

Table 1 summarizes the challenges encountered during this multi-phase optimization process, as well as the key solutions that were found to address these challenges.

<table>
<thead>
<tr>
<th>Phase</th>
<th>Primary Challenges Addressed from Previous Phase</th>
<th>Key Solutions</th>
</tr>
</thead>
</table>
| Phase II | • Data retrieval was clear bottleneck and did not scale to large populations  
• Limitations in the amount of available volatile memory prevented simultaneous processing of large populations | • Altered queries to return data for entire cohort instead of per patient  
• Parallelized data queries  
• vMR fragments stored on disk to allow parallelization |
| Phase III | • Storage of vMR fragments on disk would not scale because of limited disk space and relatively slow speed of reading and writing CLOBs  
• vMR creation and evaluation was sequential | • Stored raw patient data rather than vMR fragments into a standardized staging schema to improve caching and transformation performance  
• Parallelized vMR creation and evaluation using multi-threading and multiple servers |

CLOB = Character Large Object. vMR = Virtual Medical Record.

Scalability Analysis

Figure 4 shows the execution time for the Phase III CDS-QM framework when evaluating increasingly large cohort sizes for 22 HEDIS quality measure groups. As noted, the process scales up well for large cohort sizes, with average completion times per patient per measure group actually decreasing with large cohort sizes.
Discussion

Summary of Findings
A standards-based CDS-QM framework was enhanced across two phases in this study to enable the evaluation of increasingly large patient cohorts in a timely manner. Through key strategies including population-based data collection, parallel processing, and the use of intermediate staging tables, the CDS-QM framework achieved a performance improvement of approximately three orders of magnitude. The current CDS-QM framework is able to process 22 quality measure groups for all patients seen at least once in the past year in an academic health system in less than 5 hours.

Impact
In terms of local impact, the CDS-QM framework now allows complex clinical quality measures to be evaluated for all applicable patients within one business day, as opposed to depending on estimations based on chart audits that required weeks or months to complete. Consequently, the CDS-QM framework is enabling a number of clinical quality improvement initiatives, including those with explicit ties to physician compensation.

In terms of impact beyond our institution, we speculate that the lessons learned from this study will facilitate efforts by others to deliver operational CDS and QM using a common CDS-QM framework, thereby achieving the benefits of semantic consistency and implementation efficiency. In particular, we hope that the open-source nature of the relevant software components will encourage the adoption and community improvement of the CDS-QM framework.

Limitations and Strengths of Study
One significant limitation of this study is that execution timings were not systematically recorded, as the development of each phase of the CDS-QM framework was conducted for operational rather than research purposes. However, we believe that the exact magnitude of benefit gained from each strategy is less important than the overall magnitude of benefit gained from the combination of all strategies. A second limitation of this study is that the execution performance of the CDS-QM framework has not yet been evaluated at other institutions. Finally, the data retrieval component of our implementation is currently institution-specific. While some customization is likely inevitable for institution-specific data retrieval (e.g., to account for differing database schemas), our goal is to generalize this data retrieval component so that institution-specific customizations can be implemented with high efficiency.

An important strength of this study is that the framework described has been shown to be sufficiently robust for operational, enterprise-level use. Indeed, the analysis described in the Phase III framework is now routinely being conducted for operational clinical use. A second strength of this study is that it utilizes open-source, standards-based software components that are freely available. A third strength is the scalability analysis, which indicates that the approach scales well to increasing cohort sizes. A final strength of this approach is that it is a general-purpose framework that can be adopted to other quality measures as well as to other large-scale analysis needs, including population health management.

Future Directions
The core CDS Web service is already freely available through [www.opencds.org](http://www.opencds.org). We intend to make the other components of the CDS-QM framework also freely available after re-factoring the components for general use. We also intend to continually enhance the CDS-QM framework and its knowledge content based on the operational needs of our healthcare system and of other stakeholders making use of this framework.

Conclusion
Leveraging a standards-based CDS infrastructure for quality measurement has important benefits, including semantic consistency and implementation efficiency. We hope that the performance optimization methods identified in this study will enable such a CDS-QM approach to be more widely leveraged in operational settings to improve health and health care.

Abstract

“Identifying and labeling” (annotating) sections improves the effectiveness of extracting information stored in the free text of clinical documents. OBSeCAn, an automated ontology-based section annotator, was developed to identify and label sections of semi-structured clinical documents from the Department of Veterans Affairs (VA). In the first step, the algorithm reads and parses the document to obtain and store information regarding sections into a structure that supports the hierarchy of sections. The second stage detects and makes correction to errors in the parsed structure. The third stage produces the section annotation output using the final parsed tree. In this study, we present the OBSeCAn method and its scale to a million document corpus and evaluate its performance in identifying family history sections. We identify high yield sections for this use case from note titles such as primary care and demonstrate a median rate of 99% in correctly identifying a family history section.

Introduction

Information stored in electronic health records (EHRs) such as patient expressed symptoms, physical findings, medications, past medical history, and family history of illnesses has tremendous potential for aiding in the detection of patient care and treatment patterns, risks and outcomes of diseases, or adverse events\(^1,2,3,4\). Effective clinical text mining methods and techniques are important for the discovery of these valuable health data for clinical, operational and research purposes. Statistical text mining and natural language processing (NLP) are among the popular techniques used in the field\(^5,6\). However, the unstructured, heterogeneous, and context-dependent nature of the clinical documents has made these techniques less effective\(^6,7\). Recent efforts in the development of a section identifier and labeler for preprocessing clinical documents before applying NLP enhances their effectiveness\(^6,8,9,10\).

The section identifier and labeler OBSeCAn, which stands for Object-Based Section Annotator, was developed to preprocess the vast amount of clinical notes stored by the U.S. Department of Veterans Affairs (VA) in the Veterans Health Information Systems and Technology Architecture (VistA) network for various tasks including extracting symptoms and concepts related to specific domains of interest such as homelessness and indwelling urinary catheters. VistA clinical notes are semi-structured documents generated by entering text into pre-defined or user-defined templates\(^8\). The lack of consistency in the structure of the notes makes it difficult to solely use regular expressions to identify sections since these documents do not adhere to particular grammatical rules. OBSeCAn identifies sections and their hierarchical relationships using an ontology that describes the relevant concepts of clinical notes sections and the relationships among these concepts. OBSeCAn identifies labeled and unlabeled sections (sections with and without section headers) in semi-structured clinical documents and annotates these sections to be used for further information extraction tasks.

In a separate study, OBSeCAn was trained and evaluated on a small corpus of 1000 VistA notes including both inpatient and outpatient encounters from any medical specialty. The results showed reasonable metrics for recovering both labeled and unlabeled sections from semi-structured electronic medical notes. In this study, we use all 1000 notes to further train OBSeCAn and evaluate the performance of this method on annotating sections in one million medical documents derived from routine care offered to Veterans at VA medical facilities.

Background

This importance of and motivation for standardization of section headers in clinical notes has been addressed by many authors\(^8,8,9\). This standardization is a key step toward the creation of an ontology for clinical document sections. The existence of such an ontology may be useful for integrating and sharing clinical information among health care professionals and information systems. So far, a terminology of discovered section headers was developed for use with SecTag, a method for automated section header identification\(^8\). The SecTag method was the
first terminology-based method for identifying and labeling sections. In addition, other methods have identified and/or labeled section headers using regular expressions, rules, and machine learnings. Until now, the SecTag method and its study were the best developed and evaluated of the methods for automated section header identification. However, the development of SecTag was based on notes within the Vanderbilt EMR system and demonstrated some limitations when applied to identify and label sections of VA notes. Seeing the potential of terminology-based approach in identifying and labeling sections in the semi-structured notes within VA, OBSecAn was developed using a similar approach to that of SecTag with modifications to the section header terminology, the annotated structure, and the algorithm to provide an automated section annotator for VA notes. In this paper, we discuss the development of the OBSecAn method and its scale to VA big data.

Methods

The OBSecAn algorithm for section annotation identifies the sections and labels the unlabeled sections within semi-structured clinical documents. The components of the OBSecAn method include:

Clinical Document Sections Ontology (CDSO)

A section heading terminology was developed to provide a list of concepts and synonyms for clinical section headings and subsections. The resulting section heading terminology contained 1109 concepts with 4332 synonyms and the hierarchical relationships. As mentioned in Denny et al., the existence of section heading terminology helps to better understand clinical notes. However, we think it is important to not only standardize section headers but also standardize sections. The creation of a clinical document sections ontology (CDSO) is a step toward the standardization of sections for health data integration. The existence of a CDSO can also aid NLP and data mining tasks. For the OBSecAn method, the CDSO helps to recover unlabeled sections. For example, “regular rate and rhythm” is often used under the “Physical Exam” section of a clinical H&P note to describe a result obtained from examining the heart. In other notes the words “regular rate and rhythm” are placed under the section “heart exam” and many times the section headers for the “heart exam” section are omitted. If the phrase “regular rate and rhythm” is added into the CDSO and related to the “heart exam” section concept, it increases the chance of recognizing the “heart exam” section if it is not labelled. For the OBSecAn method, we created a very preliminary CDSO which was evolved from the section header terminology to aid the OBSecAn algorithm. Currently, we have three different types of elements within the CDSO: Section, Section Header, and Property.

A section as defined in Denny et al. is a clinically meaningful grouping of symptoms, history, findings, results, or clinical reasoning that is not itself part of the unique narrative for a patient. In the CDSO, a Section element represents a unit often being used by health care providers to group several elements that have something in common. The way to group the elements in clinical notes varies among health care providers. The CDSO aims to provide an exhaustive list of these groupings. Physicians commonly group into one section several separable sections that can be found in other notes. For example, the section labeled “personal and social history” is a composition of the sections “personal history” and “social history”. We excluded from the CDSO those sections which can be decomposed into more than one section. The structure of a Section element in the CDSO consists of a concept identification, a description, and a data type.

A Section Header element in the CDSO is a found header for a Section element. There are variations of headers being used to label the same Section element across clinical notes. There are also cases where the same header string can be used to label different Section elements. For example, the header string “Cardiac” is used to label the section “Cardiovascular Exam” as well as the section “Cardiovascular Review.” For the header string “Cardiac”, we need to know the context of the document in order to determine which clinical section is being labeled. If this header string is found under the section “Physical Exam” then it is referring to “Cardiovascular Exam”; it refers to “Cardiovascular Review” if placed under the section “Review of Systems.” To assist the OBSecAn algorithm in efficiently labeling the sections, we document in the CDSO aheaders with direct reference to the section like “Cardiovascular Exam” as explicit headers. The CDSO inherited a subset of header strings found in the section header terminology of Denny et al.. In order to achieve good coverage of the section headers found in various clinical notes, we extracted and reviewed headers that appeared frequently in more than 50,000 VA boiler-plate templates generated from all stations within the VA for additional document section headers.

A Property element in the CDSO is a term that often appears in the content of a section. One example is the phrase “regular rate and rhythm”. As mentioned earlier, Property elements in the CDSO play an important role in recovering the unlabeled sections. To generate the list of possible Property elements for a section, we use the content of the labeled sections to obtain a list of frequently found terms used in that section.
There are different types of relationships among the elements of CDSO. The parent-child relationships are added to the CDSO to represent the hierarchical structure of section concepts. The relationships among the concepts are polyheirarchical parent-child relationships. Children of a document section concept are all the subsections found for that section across the clinical notes. A child section may be a part of several different parent sections. CDSO also contains the is-Header relationships between Section Header elements and Section elements and the is-Property relationships between Section elements and Property elements. The relationships among the elements of CDSO were obtained from training on a sample of 1000 documents extracted from VistA notes.

**Section Annotation Output.** With the aim of using OBSecAn to preprocess clinical notes to be used for further focused information extraction, we saved the section annotation output outside of the original document. An example of the format for the section annotation output, viewable with Visual Tagging Tool (VTT) is shown in Figure 1.

For annotating sections in large scale, we simplify the output to contain only the information that is useful for future retrievals of the section content. Once the OBSecAn has annotated sections in a clinical note, the identification of the original document and the annotated section information are saved for future retrieval. The annotated section information includes the section identifications, the section beginning offsets, and the section ending offsets. The section beginning offsets are set to the beginning section content offsets, not the beginning section label offsets.

**OBSecAn Algorithm.** The OBSecAn algorithm has three major stages. The first stage reads and parses the document to obtain and store information regarding sections into a structure that supports the hierarchy of sections. The second stage detects and makes correction to errors in the parsed structure. The third stage produces the section annotation output using the final parsed tree.

The first stage of the algorithm involves processing the documents by sequential chunks of text and storing the processed information into a structure that supports the hierarchy of sections. A clinical note may contain a list of sections and a section may contain a list of nested sections. OBSecAn identifies sections from the note and saves the structure of those identified sections into a supported data structure. This data structure contains a list of nodes representing outermost sections called root nodes. Each node in the list again links to a list of nodes representing the nested sections. OBSecAn sequentially processes a note and creates nodes and inserts them into the data structure. An illustration of data structure used by OBSecAn to store the information of identified section is shown in Figure 2.

**Figure 1.** An example of section annotation output to be viewed with Visual Tagging Tool (VTT)

**Figure 2.** Illustration of data structure used by OBSecAn to store the information of identified sections
created root node and its linked nodes provide the context for disambiguating the next created section. Let ids₁ be the concept identification of the section in the most recent created root node. The concept identifications of the most recent created nested sections subsequently are ids₂, ids₃, ..., idsₙ. The steps for processing a clinical note are as follows:

**Select Text for Annotation.** The text from a clinical document is annotated by chunks. A chunk of text is formed by reading a line from the document. The next line of the text in the document is read and concatenated to the chunk only if the beginning of the next line is a continuation of the line that has already been read. The resulting chunk of text is then split up into segments using “dot/period (.)” as delimiter. We added an extra step to verify whether the dot/period is not a sentence delimiter but rather a decimal separator or a part of an abbreviation. Each text segment is then selected for annotation. The flow chart for annotating sections in a text segment is shown in Figure 3.

**Map Header Candidate String to Section Concepts.** A header candidate string of a text segment is either the whole text segment or the string that begins the text segment and ends right before a colon, dash, comma, semicolon, backslash, or dot. There may be several header candidate strings for a text segment. We examine the header candidate strings in sequence until we find maps of the current header candidate string to the section headers in the CDSO. As previously mentioned, a header candidate string may also be mapped to the header string of several Section concepts.

**Map the Leading Words to Section Concepts.** A section header may appear in a clinical document as leading words of a text segment. For example, the section header “Concentration” of the following text segment “Concentration is very poor”, which appears under the section “Mental Status Exam”, is not delimited from the rest of the text. In this case, we start from the first word of the text segment and find the maximum-length string which can be mapped to Section Headers in CDSO. This maximum-length string may also be mapped to several Section concepts. We also consider trimming the leading words that are prepositions or articles; for example, trimming the part “On the” in the following text segment “On the examination, temperature of the patient is 97.5.”

**Choose Best-Mapped Section Concept.** For each of the mapped Section concepts, we calculate the distance to the recently created sections ids₁, ids₂, ids₃, ..., idsₙ based on the number of unlabeled sections to be inserted into the current section hierarchy. The distance is the minimum number of sections created if the mapped Section concept is to be inserted into the current section hierarchy. The best-mapped Section Concept is the concept among the mapped Section concepts with the minimum distance to the recently created sections. The list of minimal created sections (referred to as unlabeled sections) is also inserted into the current section hierarchy along with the mapped section. In order to reduce the noise in introducing the labels to the unlabeled sections, we set thresholds for the number of created sections. The threshold is set to 3 if the mapped section is derived from mapping to Section Header elements. Otherwise, it is set to 2 if the mapped section is derived from mapping to Property elements. If the number of the unlabeled sections introduced when inserting a mapped section into the current section hierarchy exceeds the threshold for the given case, we omit the insertion of the mapped section and move forward.

**Find first occurrence of Header Strings and Property Strings of a Section.** Searching for Header Strings and Property Strings embedded in the text segment is used to discover the unlabeled sections. The list of Header Strings and Property String of Section idsₙ includes all Header Strings and Property Strings with the relationships is-Header or is-Property to Section idsₙ and its child Sections.

**Retrieve Mapped Section Concept.** The Section concepts associated with the Header String or Property String which first occurs in the text segment that are retrieved. In the case that there are several concepts associated with a Header String or Property String, we consider the best-mapped Section concept.

**Insert Mapped Section.** After a mapped section has been identified from the text segment, we create a node for the mapped section along with the nodes for unlabeled sections. These nodes are linked to the nodes in the data structure for recently created sections ids₁, ids₂, ids₃, ..., idsₙ or linked to a newly created root node.

**Select remain text for Annotation.** The part of the text segment after the text used to identify the mapped Section concept is then being annotated.
**Determining beginning and ending offsets of sections.** The beginning offset of a section is derived along with the position of the Section Header or Property related to the discovery of the section. For determining the ending offset of a section, we have used two different approaches. The first approach sets the ending offset of a section to the beginning of the next discovered section. The second approach derives the ending offset using machine learning. For the OBSecAn method, we used the first approach in which the ending offset of a section is derived from the beginning offset of the next discovered “same level” section. Though Denny et al. have shown that using machine learning could improve the accuracy in setting the section’s ending offset, it has not been tested on large corpora.

After the entire document has been processed and the data structure used to store the identified section has been built, the second stage of the algorithm proceeds to detect and make correction to the errors found in the parsed data structure. We recursively traversed the parsed data structure from the top nodes and employed the following validation checks:

- Check if there were cases that sections were discovered by mistake in the middle of other sections. As a result, in the parsed structure, the nodes corresponding to the section discovered by mistake are being deleted.
- Validate the content of the tagged section using its data type.

Once the recognizable errors in the parsed data structure had been corrected, we calculated the ending offset of the sections via the information available in the final parsed data structure and generate the OBSecAn’s output.

**Evaluation**

The evaluation of the performance of the OBSecAn method on a small corpus was done in a separate study. In this paper, the scale out of OBSecAn to a VA corpus of one million record was evaluated in three steps: (1) the estimation of disk space required to save the annotated sections vs. the original note corpus; (2) identification of high yield sections from the various note titles wherein a high yield section was determined as the ratio of the
number of an annotated section to the total number of notes; and (3) the rate of accurately identifying a particular section of notes from OBSecAn output. For this study, we have used the family history section as an illustrative example. We processed the one million records and extracted the content of the annotated family history sections. The content of these annotated sections was then written to a spreadsheet. Each row in the spreadsheet is the content of one annotated family history section. We then sorted the spreadsheet so that the rows with similar contents were clustered. These clustered rows made it easier to review in groups.

**Document Corpus**

The VA’s VistA network stores a large number of clinical notes (over 2 billion). The notes are generated from various types of medical encounters across different facilities and medical specialties; therefore, the list of sections and section structures are also varied among different type of notes. To evaluate the performance of OBSecAn on a representative sample of VA notes, we extracted a random corpus of one million notes that are stored and made available for research in a secure VA database: Veterans Informatics and Computing Infrastructure (VINCI)\(^4\). These notes organized into approximately 2819 VA Enterprise Note Titles that are further clustered into \(\sim 220\) higher level Note Titles. The million corpus represents a proportional random sample of documents based on the frequencies of the Enterprise Note titles in VINCI.

**Results**

About 75% of the notes in the million document corpus are accounted for by the top 57 Note Titles presented in the corpus (Table 1).

**Table 1.** Frequency distribution of top 57 Note Titles presented in the one-million note corpus.

**Annotating and storing sections using OBSecAn**

The original document’s identification, the section annotation output including the identification, and the beginning and ending offsets of the annotated sections were saved for use with further information extraction tasks.

For efficiency in storing and querying data, we divided the one million notes into 20 sets of fifty-thousand notes. All fifty-thousand notes in each set were concatenated and saved into one large file. A note in this large file contains the note identification, the content of the note, and the end of note delimiter. We opened a file stream and annotated sections for all the notes in each of the large file and stored the annotation output into a corresponding file. An output file included the sections annotated for all fifty-thousand notes. The annotated output for each note in the output file includes the note identification, the section annotated information, and the end of note delimiter. The
execution times and disk spaces for storing the original notes and the annotation output for each of the fifty-thousand sets of notes are shown in Figure 4.

![Figure 4](image_url)

**Figure 4.** Disk space in Kilobytes (Kb) for storing the original medical notes and the section annotation outputs for 20 sets of fifty-thousand notes each.

**High Yield Sections and Corresponding Note Titles**

The frequency of a section that appears in notes varies by Note Titles. For each of the Note Titles, the ratio of the number of an annotated section to the total number of notes was used to determine the high yield sections for the corresponding Note Title. There are sections that may appear more frequently in some note title than others. For example, it would be appropriate to expect a completed family history section in a primary care note as opposed to an administrative note. Similarly, sections pertaining to nursing assessments such as the Braden Scale or skin assessment would be expected more frequently in a nursing note. Thus, depending on the information extraction task and domain knowledge, this method would identify a high yield section for natural language processing. For a representative set of 10 of the above Note Titles, we present a list of selected sections and their frequencies (in parentheses):

**Nursing:** Vital Signs (45007), Preventative Medicine (26874), Hygiene (26261), Mobility (24369), Activity Assessment (19238), Patient Education (14050), Review Of Systems (13510), Chronic Pain History (13242), Active Medications (12862), Physical Exam (12769), Functional Status (12153), Activities Of Daily Living (11514), Skin Reassessment (11484), Mental Status (10537), Pain Assessment (10252), Braden Scale (10218), Nursing Comments (10110), Nutrition (9848), Ambulation Status (9245), Functional Status Prior To Admission (9201), Current Skin Assessment (8556), Dressing (8215), Post Op Care (7960), Lab Data (7615), Chief Complaint (7450), Nursing Activity (7253), Morse Fall Scale (7221), Nursing Assessment (7080)

**Primary care:** Vital Signs (72565), Physical Exam (64143), Assessment (46917), Active Medications (44390), Pain Exam (43442), Preventative Medicine (39120), Review Of Systems (36975), Lab Data (32048), Hx Present Illness (30968), Chief Complaint (25914), Past Medical History (17748), Family History (7022), Allergies (12388), Alcohol Audit Screening (10330), Screen For Depression (8176), Clinical Impression (6906), Colorectal Cancer Screen (6361), Reason For Visit (6306), Personal Habits (6010),

**Mental health:** Assessment (13992), Mental Status (7417), Axis I (5524), Axis II (5170), Discharge Diagnosis (4548), Axis III (4367), Axis V (3897), Axis IV (3885), Active Medications (3578), Preventative Medicine (2812), Clinical Impression (2163), Family History (1201), Goal (1040), Gaf (1028), Mental Health/psychiatric (903), Substance Abuse Hx (808), Past Medical History (797), Diagnostic Impression (791), Hx Present Illness (722),

**Inpatient:** Physical Exam (10620), Vital Signs (10128), Assessment (8869), Active Medications (5274), Active Problems (3323), Allergies (3310), Admitting Diagnosis (3224), Hx Present Illness (3131), Family History (747), Chief Complaint (2913), Vitals Interpretation (2894)
**Psychiatry:** Assessment (6381), Mental Status (4373), Axis I (3156), Axis III (3021), Axis II (3004), Axis V (2969), Axis IV (2927), Clinical Impression (2738), Discharge Diagnosis (2387), Active Medications (1920), Preventative Medicine (1433), Active Problems (1021), Additional Diagnosis (867), Family History (344), Gaf (591), Past Medical History (587), Hx Present Illness (581), Lab Data (521), Mental Health/psychiatric (333)

**Surgery:** Preoperative Diagnosis (2812), Procedure (2763), Postoperative Diagnosis (2099), Vital Signs (1692), Review Of Systems (1472), Active Meds (1145), Physical Exam (1095), Reason For Procedure (923), Past Medical History (483), Active Problems (264), Discharge Medications (248), Informed Consent (245), Advance Directive (241)

**Dental:** Diagnosis (8374), Treatment Status (3358), Problem (3254), Past Medical History (393), Medications (539), Chief Complaint (292), Previous Treatments (263), Active Problems (244)

**Physical Therapy:** Physical Exam (979), Functional Status (928), Range Of Motion Exam (811), Past Medical History (677), Statement Of Goal (584), Bed Mobility (579), Procedure (543)

**Podiatry:** Physical Exam (6853), Past Medical History (2345), Musc Exam (2254), Lymp Nodes Exam (1770), Muscle Strength (1669), Range Of Motion (1636), Previous Treatments (1570), Medications (773), Active Problems (567)

**Discharge Summary:** Assessment (7932), Course In Hospital (7255), Hx Present Illness (6076), Physical Exam (5997), Discharge Medications (5070), Discharge Diagnosis (4772), Past Medical History (3996)

**Table 2.** Family history annotations by OBSecAn on the million document corpus. Annotated sections refers to those identified by OBSecAn from the respective documents. Labeled refers to those sections that were designated as “Family History” in the note.

Accuracy of OBSecAn Annotation of Family History Section

As shown in Table 2, the family history section is present in many note titles in varying frequencies. Primary care, nursing, and mental health are the three note titles with the highest yield for family history sections. It was interesting to note that the family history section was present in nearly half the note titles. This section was labeled as such in almost all instances in all note titles. The rate of accurately identifying the family history as such was between 93% and 100% with a median of 99% in the top 20 note titles shown in Table 2. Most of the inaccuracies were due to an incorrect ending offset of the section.

Discussion

We demonstrate the feasibility of accurately identifying a specific section in VA electronic medical notes, using OBSecAn, an automated ontology-based section annotator. OBSecAn was first trained and tested on a small corpus of documents and now has been scaled out to a million documents from the VA.

Several methods have been developed to sectionize a document. Extending current methods to include a robust clinical documents section ontology and a logical sequence of steps to parse, correct, and ultimately annotate a section based on the final parsed tree are contributions of OBSecAn to the field of automated information extraction. The computational intensity of this algorithm, while significant, is feasible and practical. The stored annotations represent only a fraction of the storage needed for the original documents and thus represents economy of scale while dealing with large document corpora.

The identification of ‘high yield’ sections from specific document note titles represents another conceptual innovation that has the potential to increase the efficiency of information extraction tasks. As noted above, the family history section is present in higher frequency in certain notes, such as primary care. While this is intuitive based on domain knowledge and workflow of clinicians, it offers an objective metric to identify high yield notes based on the specific task and use case. With the example of family history, it was interesting to note that the sections were appropriately labeled as family history in nearly all the top documents identified by their frequency count of the presence of family history sections. The accuracy with which OBSecAn was able to identify a section as family history was nearly perfect in most of the high yield documents reviewed.

We acknowledge several limitations. Even though the million document corpus was representative of the entire VA document corpus, it is possible that there are variations in the documents with respect to their semi-structured format and section beginning and ending offsets. Thus, it is important to further evaluate the sectionizer on a larger scale out. Rather than brute force application of OBSecAn to a larger corpus, we are currently preparing to apply the method to a large corpus and specific use cases such as symptom extraction, homelessness, and detecting the presence of indwelling urinary catheters in hospitalized patients. Accurately identifying a section achieves only one objective. The information extraction task based on specific use cases (such as the family history example discussed above) would need to be evaluated for the relevance of the information extracted. Based on pilot reviews of the textual content of the family history section of several hundred documents, it appears there are several types of templates and free text modalities for recording the family history. Thus, extracting information from this section is a major challenge. We developed this method exclusively on VA documents and, therefore, it may not perform as well in other settings. However, we are interested in extending and applying OBSecAn to electronic notes from other healthcare systems with electronic medical records.

Conclusion

There is a growing recognition of the importance of identifying and labeling sections in clinical notes. The main purpose of the task is to provide the document context for efficient and accurate information extraction and retrieval. In this paper, we have improved on the original implementation of the OBSecAn for automated section identification on a large corpus of electronic medical notes. To the best of our knowledge, this is the first ever attempt to apply and evaluate a section annotator on a large scale.

Abstract

With the objective of increasing electronic death registration, Intermountain Healthcare and the Utah Office of Vital Records and Statistics have developed a system enabling death certification from within Intermountain’s electronic medical record (EMR), consisting of an EMR module and an HL7 interface. Comparison of post-intervention death certification at Intermountain Healthcare against a baseline study found a slight increase in the percentage of deaths certified electronically (73% pre vs. 77% post). Analysis of deaths certified using the EMR-module found that they were completed significantly sooner than those certified on paper or using the state’s web-based electronic death registration system (EDRS) (Mean time: Paper = 114.72 hours, EDRS = 81.84 hours, EMR = 43.92 hours; \( p < 0.0001 \)). EMR-certified deaths also contained significantly more causes of deaths than either alternative method (Mean number of causes: Paper = 3.9 causes, EDRS = 4.0 causes, EMR = 5.5 causes; \( p < 0.0001 \)).

Introduction

Death certificates are the primary source of death information throughout the United States. Each state maintains a central death registration system for deaths occurring in their state. As part of maintaining these registries, they institute systems to collect, validate, and archive death records. Frequently, funeral directors initiate the process of creating a new death certificate and then seek cause of death data from medical professionals, including physicians and medical examiners. A death certificate must be completed before a funeral director can proceed with the disposition (burial, cremation, etc.) of the decedent (deceased person).

Over recent years, a majority of state health departments have implemented web-based electronic death registration systems (EDRS) for the gathering and reporting of Death Certificate data.¹ EDRS have several advantages over traditional paper-based systems. Electronic systems are more efficient than paper-based systems, producing higher quality data in a more timely manner.² Paper-based systems require funeral directors to mail or hand-deliver partially completed death certificates to physician certifiers. Once completed, these paper death certificates need to be delivered, in person or by mail to local or state registrars for finalization, including typing the handwritten data into the state’s electronic death records. Electronic systems can reduce or eliminate travel costs incurred by funeral directors in tracking down physicians to complete a death certificate. It is also less likely that waiting for a physician to complete their portion of the certificate will cause delays in the disposition of a decedent. Further, entering data electronically reduces the risk of handwriting-related errors. Government registrars also save time and resources by not having to enter handwritten data into electronic databases.

In 2006, The Utah State Office of Vital Records & Statistics (OVRS) implemented and deployed an EDRS named the Electronic Death Entry Network (EDEN). Utah was the 13th state to deploy an EDRS. EDEN is available to funeral directors, physicians, and medical examiners, as well as health department officials via the World Wide Web. Using EDEN, they can enter and review data from anywhere with an Internet connection.

Problem

EDEN quickly gained nearly universal adoption among funeral directors, but was not as universally adopted among physicians. While nearly all of Utah’s funeral directors are registered users of the EDEN system, in 2010, only 591 of the nearly 5,000 Utah physicians were registered users of the EDEN system. As of March 2010, the funeral director’s portion of the death certificate was completed electronically in EDEN for virtually all death certificates. Conversely, the physician’s portion was being completed electronically for between 60% and 65% of death certificates.
It is not surprising that funeral directors have a higher EDRS adoption rate than physicians. Funeral directors have a vested interest in seeing an increase in the proportion of death certificates completed electronically. Most of the benefits gained by moving from paper death certificates to electronic death certificates accrue to funeral directors and government registrars. On the other hand, aside from the increased flexibility of being able to enter cause of death information without having to receive the paper copy, physicians do not have much to gain by switching to an electronic process. Completing a death certificate using the EDEN EDRS is more complicated for physicians than completing a paper death certificate. Physicians must set up an account on the EDRS in order to use EDEN, and then remember their login name and password in order to access it. The original EDEN user interface lacked clear instructions for novice users. All users, physicians and funeral directors alike were presented with the same screens for data entry, though each user type only needs to enter data into a subset of the available screens. It was not immediately clear to physicians how to complete their portion of the death record. From the physician’s perspective, completing a paper death certificate is much simpler. The confusion stemming from the extraneous (from the physician’s perspective) fields and screens in EDEN was one barrier to physician adoption of the EDEN EDRS.

When a physician certifier chooses not to complete a death certificate electronically, the funeral director must “drop to paper” – print out the partially completed certificate and physically deliver it to the physician for completion (Figure 1). Utah state law requires that deaths be “certified” (cause of death information completed by a licensed provider) within 72 hours of a decedent’s death, and that the death be registered (meaning the death certificate has been fully completed), within 5 days of the time of death. During the first year and a half that EDEN was in operation, 61% of cause of death data entered electronically within the EDEN system was entered within 72 hours of the time of death. When the funeral director had to use the “drop to paper” option, only 34% were certified within 72 hours.

![Figure 1. Pre-intervention death certificate workflow. FD = Funeral Director. MD = Physician. LHD = Local Health Department.](image)

Intermountain Healthcare (Intermountain) is a large integrated delivery network, centralized in the state of Utah, that provides care to approximately half the population of Utah. For death certification, Intermountain has seen EDRS adoption rates among its provider network similar to those seen statewide. During the period from January 2007 through October 2009, Intermountain physicians certified 39% of the 35,093 deaths registered in the state of Utah, 73% using the EDEN EDRS.
Many Intermountain physicians do use the EDEN EDRS for death registration. EDEN adoption rates are particularly high among physicians who complete a high number of death certificates. During the period examined, Intermountain physicians who completed an average of one or more death certificates per month used the EDEN system for 98% of the deaths they certified. This group of “high volume” death certifiers included only 3% of Intermountain physicians who completed at least one death certificate during that period, but accounted for 65% of all deaths certified by Intermountain physicians during that same period.

The vast majority of Intermountain physicians fell into the much larger group of “low volume” death certifiers, certifying less than one death per month on average. These physicians only used the EDEN system for 28% of the deaths that they certified. The large number of “low volume” certifiers collectively represents a “long tail” that accounted for 35% of death certificates completed by Intermountain physicians between January 2007 and October 2009, but only 13.5% of death certificates certified electronically (Table 1). Nearly three-fourths (74%) of the physicians who certified at least one death during the study period certified less than 1 death per year, and these “very low volume” certifiers were even less likely to use the EDEN system, completing only 12% of their death certificates electronically.

Table 1 - Use of EDRS by Intermountain physicians grouped by number of deaths certified per month; Baseline study - January 2007 to October 2009.

Solution

With the objective of increasing electronic death certification, OVRS applied for and received a grant from the Centers for Disease Control and Prevention (CDC) to implement an electronic cause of death interface between the EDEN system and the HELP2 electronic medical record (EMR) system in place at all Intermountain hospitals and clinics. Intermountain has a history of collaborating with the Utah Department of Health (UDOH), especially for electronic data exchanges. The development of this death certificate interface between Intermountain and UDOH is the first instance in the country of death certification done from within an EMR.

This system, that allows deaths to be certified from the EMR, consists of two key components: an EMR module that allows physician users to input the required cause of death data for death certification, and an HL7 interface that allows these data to be transmitted from the EMR to OVRS. Both of these components were developed following significant discussion and collaboration between technical, clinical, and administrative personnel at Intermountain and OVRS, as well as input from the Utah Funeral Directors Association.

The user-facing EMR module was designed in a manner consistent with National Center for Health Statistics (NCHS) standards. The module allows providers to enter cause of death data for a decedent without needing to directly access the EDEN system, eliminating the need for them to remember a separate login and password. As this module was built specifically to be used by physician certifiers, it only includes data fields for the physician’s portion of the death certificate, eliminating some of the confusion physicians had experienced when using OVRS’s EDEN EDRS. (Figure 2)

In addition to simplifying and streamlining the physician certifiers’ data entry process, the new EMR module provides users with access to detailed instructions, produced by the CDC, for properly completing the cause of death section of the death certificate, to support especially those physicians who only certify deaths infrequently. Because the module is integrated into the EMR, it is able to automatically populate required demographic fields, including name, date of birth, gender, and social security number. Stored certifier user data is also automatically entered into the required fields for certifier name, license number, and mailing address. Another advantage of completing a
death certificate from within the EMR is that certifiers can easily switch back and forth between the death certificate module and other portions of the decedent’s medical record (progress notes, laboratory data, medication history, etc.) to gather relevant data for completing the cause of death portion of the death certificate.

**Figure 2 - Demographics and Cause of Death sections of EMR-based death certificate module**

In order to transmit the cause of death data from Intermountain to OVRS, an HL7 interface for cause of death data was created. This HL7 interface supports three distinct types of messages: (1) an ADT^A04 (Patient registration) message is used when sending a new cause of death record to OVRS, (2) an ADT^A08 (Update patient information) message is used to send an update to an already submitted record, and (3) an ADT^A23 (Delete patient encounter) message is used to notify OVRS that a record was submitted in error and should be deleted. Delete messages do not trigger an automatic deletion of a record, as it was determined that personnel at OVRS would like to manually follow up on those instances before a cause of death record is deleted.

The initial HL7 messages were a version 2.4 format agreed upon by engineers at OVRS and Intermountain. As this project grew in national prominence, leaders at the National Center for Vital and Health Statistics (NCVHS) proposed that a standard HL7 message format be developed for use in sending death certificate records from EMRs to electronic vital records registration systems. That proposal led to the development of an HL7 draft standard for trial use that uses HL7 version 2.5.1 messages. Engineers at Intermountain and UDOH OVRS helped to define and vet this standard, and have updated our interface from the original version 2.4 messages to the new standard.
Once these data have been received, they are merged with the funeral director’s portion of the death certificate that continues to be entered into OVRS’s EDEN system. The demographic data in the physician’s portion of the record are compared against records created in EDEN by funeral directors. These demographic data include decedent name, social security number (if applicable), date of birth, gender, and date of death. If a match is found, the two records are merged. In the event of a non-perfect demographic match, records can be reviewed and a merge can be manually triggered by administrative staff at OVRS. OVRS staff report that approximately 40% of the records merge automatically, with the remaining 60% requiring the manual review step.

In addition to transmitting cause of death data to OVRS, Intermountain also stores a copy of the cause of death in the Intermountain Clinical Data Repository (CDR), fulfilling the Meaningful Use Core Measures requirement to record the “Date and preliminary cause of death in the event of mortality in the eligible hospital or CAH.”

The new workflow associated with the EMR-based death certificate module is as follows: When a death occurs, the funeral director and physician can both complete their portions of the record independently and asynchronously, the funeral director using the EDEN EDRS, and the physician using the EMR module. When the funeral director has completed their portion of the record in EDEN, they can check to see if a physician has already completed their portion. If they have not, they contact the physician by telephone or e-mail as before. With the convenience of completing death certificates from within the EMR, some physicians routinely complete their portion of death certificates even before receiving notification from a funeral home. In that scenario, the funeral director now does not need to contact them, and can wait for the two portions of the record to be matched and merged. (Figure 3)

Figure 3. Post-intervention death certificate workflow with electronic interface from Intermountain EMR to EDEN EDRS. FD = Funeral Director. MD = Physician. LHD = Local Health Department.

Despite being fully developed by 2010, due to competing information systems priorities at Intermountain, the death certificate module in Intermountain’s HELP2 EMR only went into pilot production in March of 2011 with pilot users at both inpatient and outpatient sites, and was not available broadly throughout Intermountain Healthcare until July 2013.

Methods
With the module finally available to most Intermountain physicians, we wanted to assess the impact of being able to complete death certificates from within the EMR. Data was gathered for all deaths occurring in 2014 that were registered in the state of Utah, and compared them against the baseline data for deaths occurring between January 2007 and October 2009.

As the EMR-based death certificate tool was only available to physicians affiliated or employed by Intermountain, we limited the analysis of these data to those providers. Presence of a certifier’s license number in Intermountain’s master service provider registry numbers was used as an indicator of whether or not a physician certifier would have been likely to have had access to the EMR-based death certificate module. Each death was classified according to the method by which it was certified, whether it was certified on paper (“Paper”), via direct use of the EDEN EDRS (“EDEN”), or by using the EMR death certificate module and associated HL7 interface (“EMR”).

We wanted to know whether the introduction of the EMR death certificate module would increase of the proportion of deaths certified electronically at Intermountain, and whether it would increase the percentage of “low volume” certifiers certifying deaths electronically, or simply result in certifiers who were already certifying deaths electronically switching from one electronic method (the EDEN EDRS) to another (the EMR-based death certificate module). To assess the impact of the EMR death certificate module on “low volume” certifiers, we looked at the proportion of deaths certified by each method within certifiers groups stratified by the number of deaths they certified in 2014.

To assess the impact of the EMR death certificate module on the “timeliness” of death certification and registration, we calculated what percentage of deaths certified by each method of death certification (“Paper”, “EDEN”, and “EMR”) was certified within 72 hours of the recorded time of death, together with average time of certification for each method. We also calculated the percentage of deaths certified by each of the three methods that was fully registered within the 5 days allowed under state statute, together with the average time of registration for records in each category.

Additionally, to assess whether having the death certificate certified from within the decedent’s medical record (in the EMR) aided certifiers in more completely describing the cause of death, we calculated the average number of ICD-10 codes assigned to each category of death certificates by coders at the National Center for Health Statistics (NCHS).

**Results**

In 2014, 17,267 deaths were registered with the Utah Department of Health’s Office of Vital Records and Statistics. Of these, 13,249 (77%) were certified by 1537 providers whose license numbers were in Intermountain Healthcare’s service provider registry. Of these 13,249 deaths, 3,051 (23.0%) were certified by 971 certifiers using the “drop-to-paper” method and 10,198 (77.0%) were certified electronically by 675 certifiers, either by using the EDEN EDRS system directly, or by using the EMR-based death certificate module. The 77% certified electronically represents a statistically significant increase over the 73% done electronically in the period from January 2007 to October 2009 (p < 0.001, student’s t test). Of the 10,198 deaths certified electronically, 751 were completed by 181 certifiers using the EMR-based death certificate module, 7.4% of electronically-certified deaths, and 5.7% of all Intermountain-certified deaths in 2014.

Stratifying certifiers by the average number of deaths they certified each month (Table 2), we found that the increased proportion of records certified electronically in 2014 was almost entirely due to a nearly 20% increase in the proportion of records certified electronically by the “low volume” certifiers (those certifying less than 1 death per month). This increase included a 9.5% increase in deaths certified in the EDEN EDRS system, and 10% of deaths certified by this group of certifiers being certified using the now available EMR-based death certificate module. The majority of deaths certified by higher volume certifiers continued to be done electronically, though not quite at the near universal rate seen in the baseline analysis.

On average, deaths certified on paper took 4.78 days from the time of death until the time of certification, with 35.5% being certified within the state-mandated 72 hours. Deaths certified via the EDEN EDRS took an average of 3.41 days, with 56.6% certified within 72 hours of death. Deaths certified via the EMR-based death certificate module took an average of 1.83 days, with 77.5% certified within 72 hours of death. (Table 3)
Table 2 - Comparison of death certification methods used, stratified by the frequency of deaths certified, for baseline (2007-2009) and post-intervention (2014) periods.

Death registration (full completion of the death certificate) for deaths certified on paper took an average of 5.38 days, with 58.5% being fully registered within the 5 days specified by state law. Deaths certified in the EDEN EDRS were registered, on average, 4.55 days after the death, with 68.6% being registered within the mandated 5 day period. Deaths certified in the EMR-based death certificate module were registered in an average of 4.18 days from the time of death, with 74.7% being fully registered within 5 days. Deaths certified via the EMR-based death certificate module were certified significantly sooner than those done using the EDEN EDRS (p < 0.0001, student’s t test). Deaths certified in the EMR were also registered significantly sooner than those certified using the EDEN EDRS (p = 0.0086, student’s t test). (Table 3)

Table 3 - Comparison of timeliness of certification (completion of the physician’s portion of the record) and registration (full completion of the record), as grouped by method of certification. *= p-values calculated using student’s t test.

The average number of ICD-10 coded causes of death assigned by NCHS coders to deaths certified on paper was 3.9. The average number of coded causes of death assigned to deaths certified via the EDEN EDRS was 4.0. The average number of coded causes of death assigned to deaths certified using the EMR-based death certificate module was 5.5. The difference between number of coded causes of death for the paper-certified and EDRS-certified deaths was not statistically significant (p = 0.2049, student’s t test), but the difference between the number of coded causes of death for the EMR-certified deaths was significantly higher than both paper-certified deaths (p < 0.0001, student’s t test) and EDRS-certified deaths (p < 0.0001, student’s t test).
Discussion

In the period between 2009 and 2014, the percentage of deaths certified electronically at Intermountain Healthcare increased from 73% to 77%. This increase was statistically significant, but relatively modest in size, still requiring funeral homes to hand deliver nearly 1 of every 4 death certificates to physicians for certification.

The increase in the overall percentage of deaths certified electronically corresponds with increased electronic certification among certifiers who certified less than 1 death certificate per month. All other strata actually saw a decrease in the percentage of deaths certified electronically, as compared with the baseline study, but because the “low volume” certifiers certify such a large percentage of deaths, the increase in electronic certification in that stratum of certification was enough to increase the overall percentage of deaths certified electronically.

The introduction of a death certificate module within Intermountain’s HELP2 EMR may have contributed a small amount to that increase, especially considering that the increased percentage of deaths certified electronically by “low volume” certifiers was shared about equally between the state’s EDRS and Intermountain’s EMR-based module. However, to date, adoption of the EMR-based death certificate module by Intermountain physicians has been relatively low. Only about 12% of Intermountain certifiers used the EMR-based module to complete at least one death certificate.

We examined the mode of death certification in frequency-based strata because of our hypothesis that the EMR-based module might be more user-friendly for providers who only certify death rarely. However, in light of the fact that the number of providers in most of the frequency-based strata changed significantly between the times of the two samples, it is difficult to attribute much of the changes between the sample periods to changes in behavior by individual providers. In the post-implementation sample, all but the lowest volume stratum had many more certifiers than in the pre-implementation sample, so changes in mode of certification in each stratum are more likely to have come from the behavior of different physicians being in those strata than to have come from a change in behavior by individual physicians. For example, in the “high volume” stratum, the percentage of deaths certified on paper increased from 0.1% to 2.8%, but the number of certifiers increased from 13 to 38. It seems more likely that the increase of paper-based certification is due to a few more physicians who typically certify deaths on paper certifying more than five deaths per month in 2014, than it is due to physicians who previously certified deaths electronically switching back to certifying them on paper.

In each of the frequency-based strata, the EDEN EDRS was used more frequently for death certification than the EMR-based module. The EMR-based module was used most frequently by certifiers completing 4 or fewer death certificates each month. In the “high volume” stratum, certifiers used the EDEN EDRS almost exclusively when certifying deaths electronically. The “high volume” certifiers were already certifying nearly all of their deaths using the EDRS prior to the implementation of the EMR-based option, and perhaps the benefits of the EDRS outweigh those of the EMR-based option for high volume certifiers.

The web-based EDEN system can be used anywhere that a browser is available, while the EMR-based death certificate module requires the installation of a bit of software on each computer where it is to be used. This generally limits use of the EMR-based module to only those computers in Intermountain hospitals and clinics. Additionally, during this time the study was done, OVRS introduced a physician-specific portal for the EDEN system (EDEN MD) that simplifies and streamlines the physician’s part of the process, a significant improvement over the original EDEN system. Additionally, use of the EMR death certificate module has not been mandated at Intermountain, and while most physician certifiers have access it, they may not be aware of its availability. Going forward, efforts could be made to advertise the module’s existence, highlighting some of its conveniences. The small, but not insignificant, rate of the module’s use among low volume certifiers shows some promise that further growth could be seen among that group.

It should not be surprising that deaths certified electronically are both certified and registered significantly sooner than deaths certified on paper, but it is interesting that deaths certified using the EMR-based module are certified and registered significantly sooner than those completed using the state’s web-based EDRS. While it is possible that the early adopters of the EMR-based module are inherently more likely to complete deaths sooner than other certifiers, there are several factors that contribute to the increased timeliness of the EMR-certified deaths. First, the certifiers use the EMR regularly as part of their daily medical practice, and often complete other clinical notes.
related to a patient’s death. A physician completing other clinical documentation on a patient death can simply click over to the death certificate module and certify the death as well. Additionally, certifiers using the EDRS must first wait for a funeral home to begin a death record and then notify them that it is ready for them to certify. This notification may not come at a time when it is convenient for the certifier to log into the EDRS and complete the record, increasing the length of time before the death is certified and ultimately registered.

In addition to being completed significantly sooner than EDRS-certified deaths, the EMR-certified deaths contained significantly more information, as represented by the number of causes of death reported, than either EDRS-certified or paper-certified deaths. Certifiers using the EMR-based module can click back and forth between the death certificate module, and other EMR modules, including clinical notes, lab results, vital signs, etc. One physician reported that, when completing a death certificate within the EMR, he often reviews a patient’s history & physical (H&P) note, and the death summary note to better understand the chain of events leading up to a patient’s death. Further analysis is needed to determine whether the increased number of causes of death in the EMR-certified records can be attributed to having convenient access to the decedent’s medical record, but it seems likely that this would at least contribute to the increase in information reported.

It should be noted that this was not a randomized trial of the EMR-based death certificate module, and physician certifiers were at liberty to use or not use the module as they chose, so there is a possibility of selection bias. It may be that those physicians who choose to use the EMR-based module over the state’s EDRS or paper are more likely than other physicians to complete their death certificates quickly, and include more causes of death.

As mentioned above, one outcome of this work has been the creation of an HL7 Draft Standard for Trial Use for death reporting, specifically designed for the transmission of death certification records from an EMR to an EDRS. That standard has been implemented in the interface between Intermountain Healthcare and the Utah Department of Health’s Office of Vital Records and Statistics. Intermountain is currently transitioning from a set of home-grown EMR applications to a widely used commercially-vended EMR system. As part of that transition, the vendor has added a form for death certification to their EMR. This EMR is now in place at a few facilities, and records entered into its death certificate form are subsequently formatted using the HL7 Draft Standard and transmitted to the EDEN EDRS, using the same interface used for death certifications coming from the HELP2 EMR. Other customers of this commercial EMR could potentially use this same death certificate form and message format to send death record electronically to a government-run EDRS. While Utah’s EDEN system is currently the only EDRS supporting this standard, its implementation in one of the more widely used commercial EMR means that other healthcare organizations that use that EMR could potentially begin certification of deaths from within an EMR. These steps open the door to the standard’s implementation in other EDRS, and the possibility of more widespread EMR-based death certification.

Future Directions

Going forward, there are a variety of enhancements that could be made to the EMR-based death certificate module to increase its utility. Plans for future versions of the module include presenting relevant data (labs, progress notes, etc.) to the end user within the module itself, eliminating the need for switching between modules. There continue to be concerns about the accuracy of death certificates11,12, and another possible enhancement to the EMR-based module would be to develop decision support logic that uses existing patient data to make suggestions of conditions that ought to be considered among the causes of death. Additionally, enhancements to the communication aspect of this system could be made, including supporting the capability of funeral directors to trigger death certificate requests to Intermountain physicians via the EMR’s secure internal messaging system.

Conclusions

The partnership between Intermountain Healthcare and the Utah Office of Vital Records and Statistics succeeded in implementing the first ever EMR-EDRS interface for electronic death certification. To date, the EMR-based death certificate module has had limited adoption among Intermountain certifiers, primarily among users certifying 4 or fewer deaths per month. Still, it may have had a modest impact on the significant increase in electronic death certification at Intermountain Healthcare. Deaths certified using this module were completed significantly sooner than deaths certified using the state’s electronic death registration system, and included significant more causes of death.
death, so there is strong incentive to work to increase the use of this method, both within Intermountain Healthcare, and at other sites in Utah, and in other states.

A Method to Compare ICF and SNOMED CT for Coverage of U.S. Social Security Administration’s Disability Listing Criteria
Samson W. Tu, MS, Csongor I. Nyulas, Tania Tudorache, Mark A. Musen
Stanford University, Stanford, CA, USA

Abstract
We developed a method to evaluate the extent to which the International Classification of Function, Disability, and Health (ICF) and SNOMED CT cover concepts used in the disability listing criteria of the U.S. Social Security Administration’s “Blue Book.” First we decomposed the criteria into their constituent concepts and relationships. We defined different types of mappings and manually mapped the recognized concepts and relationships to either ICF or SNOMED CT. We defined various metrics for measuring the coverage of each terminology, taking into account the effects of inexact matches and frequency of occurrence. We validated our method by mapping the terms in the disability criteria of Adult Listings, Chapter 12 (Mental Disorders). SNOMED CT dominates ICF in almost all the metrics that we have computed. The method is applicable for determining any terminology’s coverage of eligibility criteria.

Introduction
Under Title II of the Social Security Act, the U.S. Social Security Administration (SSA) provides Disability Insurance (DI) benefits for workers. Under Title XVI of the Act, the SSA administers Supplemental Security Income (SSI) payments for the poor, aged, and disabled with no or little work experience. Each year, SSA renders decisions on millions of cases at the initial and subsequent reconsideration and appeal levels. To determine whether an adult is disabled, SSA’s regulations provide a five-step sequential evaluation process, based on the statutory definition of disability. The third step in the sequential evaluation process for an adult claimant is the “listing level”, where an SSA claim adjudicator determines whether the severity of a claimant’s impairment meets or medically equals a specific listing and whether the impairment meets a duration requirement. The listings are enumerated and organized into organ-system–dependent chapters in SSA’s “Blue Book,” which has separate parts for adult and childhood listings. Figure 1 shows a partial view of the Blue Book’s chapter on adult mental disorders.

At present time the evaluation of disabilities is largely a document-driven process, where only the International Classification of Diseases (ICD) is used to code data relating to diseases. If more structured data documentation can be introduced into the process, it will have enormous impact on the ability to expedite the evaluation process, to enhance the collection of health statistics, and to enable health service research on disabilities. On September 9, 2011, the Health IT Standards Committee’s Clinical Quality Measures Workgroup and the Vocabulary Task Force jointly recommended that, for functional status, International Classification of Functioning, Disability and Health (ICF) be used for coding categories of function, Logical Observation Identifiers Names and Codes (LOINC) be used for assessment instruments, and SNOMED CT be used for appropriate responses [1].

SNOMED CT and LOINC are well-known standard terminologies in biomedical informatics. ICF is a multipurpose classification that, together with ICD, is a reference classification in the WHO Family of International Classifications (WHO-FIC). It provides a standard language and conceptual basis for the definition and measurement of functions and disability. Unlike a medical model of disability, which sees loss of functions only as consequences of diseases and disorders, ICF embodies a “bio-psycho-social synthesis” that conceptualizes function and disability in the context of health conditions, environmental factors, and personal factors. Therefore ICF codes are organized as hierarchies within the ICF components Body Function, Body Structure, Activity and Participation, and Environmental Factors [2].

1 20 C.F.R. §§ 404.1520 and 416.920
2 http://www.ssa.gov/disability/professionals/bluebook/AdultListings.htm
The Blue Book listing criteria, because of its use in making decisions about claimants’ eligibility, plays a central role in defining the type of data that should be captured in the evaluation process. In particular, because several chapters of the Blue Book include criteria that require the assessment of a claimant’s functional capacity, we developed a method to investigate the extent to which ICF and SNOMED CT can be used to code the concepts and relationships appearing in the listings. To derive the concepts and relationships that should be mapped, we decomposed the listing criteria using a structured schema. To take into account inexact matches between listing concepts and terms from ICF and SNOMED CT, we defined different mapping types. We defined various metrics for measuring the coverage of each terminology, taking into account the effects of inexact matches and frequency of occurrence. Finally, we performed a proof-of-concept validation of our method by mapping the terms in the disability criteria of Adult Listings, Chapter 12 (Mental Disorders). In this small-sample study, we found that SNOMED CT dominates ICF in almost all the metrics that we have computed.

**Methods**

The first problem in using ICF to code health and health-related states is that ICF codes (such as “b210 Seeing functions”) denote possible body functions, body structures, activities and participations, and environmental factors that may affect a person’s function. They are not codes for specific conditions that a person may have. These codes need to be combined with *qualifiers* (such as “3 Moderate Impairment”) in order to describe a health-related state. To map disability criteria into ICF codes, it is necessary to decompose descriptions of a claimant’s physical and mental states into a format that facilitates matching ICF’s specific coding scheme. Much has been written on the representation of eligibility criteria [3]. For this coverage study, we adapted our earlier work on annotating human study eligibility criteria [4] to create a *mapping schema* that specifies, for a particular listing criterion, how to identify concepts and relationships in the criterion and how to decompose them in a structured format that makes clear the semantic roles played by these concepts and relationships. For example, the criterion
A residual disease process that has resulted in such marginal adjustment that even a minimal increase in mental demands or change in the environment would be predicted to cause the individual to decompensate can be decomposed into the concept *residual disease process* having the relationship *has result* with another complex concept Y, where Y can be structured as a marginal adjustment that is defined by another complex concept *a minimal increase in mental demands or change in the environment would be predicted to cause the individual to decompensate*. We decompose the concept recursively until we end up with atomic concepts and relationships that cannot be further decomposed. These atomic concepts and relationships are the entries that we want to map to standard terminologies.

More specifically, we define as atomic a *Primitive Concept* (an entity representing an idea that stands by itself and that we don't further decompose (e.g., *disease process*)), a *Qualifier* (a relationship or attribute that can be used to specialize the meaning of a concept; e.g., *result in*), and a *Qualifier value* (an attribute value that describes a quality of the thing represented by the concept; e.g., *high*). Because of our special interest in ICF, we define *Function* (e.g., *short-term memory*) as a special kind of *Primitive Concept*.

We define composite concepts recursively using other concepts and relationships. A *Boolean concept* is made up of a combination of other concepts using Boolean operators *AND*, *OR*, and *NOT*. A *Qualified concept* consists of a root concept and a set of *Qualifiers* and *Qualifier values* that are implicitly combined using *AND*. A *Change in function* concept consists of a concept representing one or a combination of functions and a change descriptor (an instance of *Qualifier value*), such as *impaired* or *significant loss*, that describes how the function has changed. Finally, we have an *Event collection* concept that represents a set of events (e.g., *repeated episodes of decompensation*). An instance of *Event collection* that is associated with a concept (e.g., *decompensation*) represents multiple occurrences of the event signified by the concept.

We define *Mapping* as having two properties: a *Mapped code* and a *Mapping type*. An instance of *Mapped code* principally contains attributes that identify the code and terminology of the matched concept. We defined five different types of mappings, as shown in Table 1.

<table>
<thead>
<tr>
<th>Mapping type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>equivalence</td>
<td>The mapped code is equivalent to the concept, qualifier value, or qualifier being mapped</td>
</tr>
<tr>
<td>generalization</td>
<td>The mapped code is a generalization of the concept, qualifier value, or qualifier being mapped</td>
</tr>
<tr>
<td>specialization</td>
<td>The mapped code is a specialization of the concept, qualifier value, or qualifier being mapped</td>
</tr>
<tr>
<td>partial match</td>
<td>The meanings of the mapped code and the concept, qualifier value, or qualifier being mapped overlap</td>
</tr>
<tr>
<td>related</td>
<td>The mapped code is related to the concept, qualifier value, or qualifier being mapped, although their meanings don't overlap</td>
</tr>
</tbody>
</table>

We modeled the mapping schema in Protégé, an ontology editor developed at Stanford. In addition to the types of concepts and qualifiers, mapping code, and listing criteria, we have classes that represent the ICF chapters and criteria groups in a chapter. The result is a small ontology consisting of the entities (Figure 2) and properties of the mapping schema.

Protégé allows us to model the groupings of the criteria in a Blue Book chapter and to annotate the criteria with concepts, to decompose the concepts, and to map the concepts to codes in terminologies that are available in Bioportal, a repository of biomedical ontologies and terminologies maintained by the National Center for Biomedical Ontologies.

---

3 More information about Protégé can be found at http://protege.stanford.edu

4 http://bioportal.bioontology.org
Figure 2. Class hierarchy representing entities in the mapping schema. Entities in the Annotatable class hierarchy allow us to represent the Listing_criteria of a Listing_chapter as part of Criteria_groups. The Listing_criteria are decomposed into their constituent Primitive_concept, Qualifiers, and Qualifier_values, which have Mappings that map them to Mapped_code from standard terminologies.

A Bioportal reference widget [5] for Protégé allows us to search for terminology codes available in Bioportal from within Protégé (Figure 3). We configured this widget for the has_mapped_code property. A user needing a code for the property can search within the widget codes or terms in specified terminologies or ontologies. Once he or she decides that a particular code is appropriate, clicking the "Import" button automatically creates, in Protégé, the mapped code corresponding to the selected code in the search results.

Once we had defined the mapping schema, two developers independently decomposed the criteria in the Adult Mental Disorder chapter of the Blue Book and mapped the concepts and relationships derived from the decompositions to ICF and SNOMED CT. They reconciled their work to come up with the consensus decompositions and mappings. To allow people not familiar with Protégé to access the mappings, we wrote scripts that export the mapping into a variety of formats, including HTML and text (Figure 4).

Next we define the metrics for quantifying the mapping results. Evaluations of a terminology's coverage of a subject domain usually define coverage as the proportion of terms and relationships harvested from a corpus in the subject domain that can be represented using terms and relationships in the terminology [6-12]. The coverage metrics may be refined by assigning “importance” weights to the concepts to be matched [7], by weighing the quality of matches [12], by the use of post-coordinated concepts to match target terms [10], and by the frequency of occurrences of the concept in the corpus [10]. Because the decompositions of different criteria may contain the same concepts, the leaf instances in our decompositions of listing criteria include duplicate concepts. Furthermore, sections of the Mental Disorders chapter may contain criteria that already occur in other sections. Together with the two weighting schemes
of the mapping types (equal weights or weights of \{1.0, 0.7, 0.7, 0.5, 0.3\} for the 5 mapping types \{equivalence, generalization, specialization, partial match, related\}), we can define 6 metrics as shown in Table 2.

Figure 3. The use of Bioportal reference widget in Protégé to search for 'short term memory' in ICF. The widget matches the search term among all descriptors of entities in the selected ontology and displays the search results (e.g., "b1440. Short-term memory") as rows in a table. To the right of each search result there are clickable buttons to perform operations such as importing the selected term into Protégé ontology.

We wrote code to traverse the consensus Protégé data structure of criteria, their decompositions, and mappings to output the criteria, concepts, and mapping information to a spreadsheet. The computation of metrics was implemented in Excel. We ran the code for SNOMED CT mappings and for ICF mappings.

Because ICF is designed to capture results of functional assessments, it necessarily has poor coverage of non-functional concepts. To correct for this bias, we made a tentative assignment of the criteria into functional and non-functional groups, and computed the metrics for each group.

Finally, we disaggregated concepts, qualifiers, and qualifier values and examined the coverage of ICF and SNOMED CT for them separately.

Results

In this proof-of-concept experiment, we found that the Adult Mental Disorders chapter of SSA’s Blue Book has 58 distinct “atomic” criteria that are not defined in terms of other criteria. These criteria reference 114 distinct atomic concepts, 18 distinct qualifiers, and 40 distinct qualifier values. There are numerous groupings of criteria. For example, Generalized persistent anxiety is defined in terms of subcriteria such as Motor Tension and Apprehensive expectations. Generalized persistent anxiety itself is part of a group of criteria used to define Anxiety-related disorders. In the tables that display the results of our mappings, “criteria” refers only to the atomic criteria, not the higher-level criteria that are defined in terms of other subcriteria.

Tables 3 and 4 display the coverage metrics of ICF and SNOMED CT for concepts, qualifiers, and qualifier values (Results for ICF mappings have shaded background in the tables for better readability.) As to be expected, SNOMED CT has a higher percentage of mapped concepts. We can also see that functional criteria are often duplicated in different sections of the chapter. So that when we weigh the metric to include all occurrences of concepts anywhere in the chapter (column 4 of each table), the metrics of ICF coverage for the functional criteria are significantly higher than when we consider only mappings of distinct concepts and qualifiers.

What may be surprising in Tables 3 and 4 is that SNOMED CT also dominates when we examine the functional criteria alone. The relatively low coverage rate of ICF, however, can be explained in part by the low coverage of qualifiers and qualifier values, especially qualifiers. If we compare the mapping rates of concepts only, excluding qualifiers and qualifier values, as shown in Tables 5 and 6, the rates of mappings for functional criteria increase substantially. In fact, if we measure in terms of the all occurrence of concepts in functional criteria, ICF has slightly
higher coverage (86.7%) than SNOMED CT (84.39%). This finding results from relatively higher frequent
occurrences of functional criteria in the Adult Mental Disorders chapter of the SSA’s Blue Book.

We can also see that the reduction in the metrics when we give inexact matches less weight is smaller in the case of
SNOMED CT mappings than that of ICF mappings. This can be explained by the more granular nature of SNOMED
CT concepts, which leads to more exact matches.

Discussion

We have developed a method for evaluating the extent to which ICF and SNOMED CT cover the concepts and relationships used to describe SSA Blue Book listing criteria. We applied the method to the criteria of the Adult Mental Disorders chapter and computed a number of metrics for comparing the coverage of the two terminologies. Our findings suggest that, compared to ICF, SNOMED CT has broader coverage of both functional and non-functional concepts in a Blue Book chapter that is rich in functional assessment. This result, if validated by larger scale studies not only in the area of listing criteria but also in the vocabulary used in, for example, assessment instruments, raises questions about the roles ICF and SNOMED CT should play in standardizing terminologies used in functional assessment. In an ideal world, ICF and SNOMED CT are harmonized so that SNOMED CT’s more granular vocabulary can enrich and complement ICF’s systematic descriptions of functions, disabilities, and factors that affect them.
The results reported in this paper should be considered preliminary, as the sample size of criteria used in the experiment is small and the concept decomposition, terminology mappings, and characterization of criteria as functional and non-functional had not been checked by experts on disability determination and terminologies. Nevertheless the qualitative results probably hold. SNOMED CT is a much larger terminology than ICF. The range and granularity of SNOMED CT lead to higher coverage rate of concepts used to define Mental Disorders criteria.

The size and complexity of SNOMED CT, however, means that finding the right mappings is a more error-prone process. Furthermore, SNOMED CT allows multiple decomposition and mapping possibilities. In particular, concepts described by SNOMED CT clinical findings often can be defined by a combination of observable entity and qualifier values. For example, the Mental Disorders concept "Impaired memory" can be mapped to either “Impaired memory” (clinical finding 386807006) or a Change function combination of “Impaired” (qualifier value 260379002) and “Memory function” (observable entity 303116000). A more granular mapping (e.g., using the observational entity and qualifier value combination instead of a single clinical finding concept) will drive up the coverage ratio.

The innovation of this work involves the development of a structured decomposition method for identifying appropriate concepts, qualifiers, and qualifier values in complex criteria that should be mapped to standard terminologies. This decomposition defines the semantic roles that the entities play in helping to define the meanings of these concepts. This decomposition is essentially a kind of post-coordination. As such, it can be formalized in description logic. For example, a qualified concept consisting of a root concept C, a qualifier Q, and a qualifier value V is essentially an OWL class expression (using the Manchester Syntax: C AND (Q some V)). Given this interpretation of decomposition, we can generate logic expressions that capture much of the meanings of the disability criteria, as was described in [4]. Given appropriate data, we can use a description-logic reasoner to classify the data to determine whether they satisfy the logical expressions, potentially providing a method to help determining whether a claimant is eligible for disability benefits.

Conclusions

We developed a structured decomposition method for identifying appropriate concepts, qualifiers, and qualifier values that occur in eligibility criteria and that should be mapped to standard terminologies. A proof-of-concept application of this method to the Adult Mental Disorders chapter of SSA’s Blue Book listing criteria shows that SNOMED CT has significantly higher coverage of functional and non-functional concepts than ICF. While the method is applicable to terminology coverage studies involving complex criteria, the specific findings of the proof-of-concept experiment need to be further validated by disability determination and terminology experts in larger studies.

Use of Patient Portals for Personal Health Information Management: The Older Adult Perspective

Anne M. Turner, MD, MLIS, MPH1, Katie Osterhage, MMS1, Andrea Hartzler, PhD2, Jonathan Joe, BS1, Lorelei Lin, BA1, Natasha Kanagat, MPH1, George Demiris, PhD1

Abstract
The personal health information management (PHIM) practices and needs of older adults are poorly understood. We describe initial results from the UW SOARING project (Studying Older Adults & Researching Information Needs and Goals), a participatory design investigation of PHIM in older adults (60 years and older). We conducted in-depth interviews with older adults (n=74) living in a variety of residential settings about their management of personal health information. A surprising 20% of participants report using patient portals and another 16% reported prior use or anticipated use of portals in the future. Participants cite ease of access to health information and direct communication with providers as valuable portal features. Barriers to the use of patient portals include a general lack of computer proficiency, high internet costs and security concerns. Design features based on consideration of needs and practices of older adults will facilitate appeal and maximize usability; both are elements critical to adoption of tools such as patient portals that can support older adults and PHIM.

Keywords:
Patient portals; older adults; health information management

Introduction and Background
A patient portal is a type of personal health record (PHR) that is connected to an electronic health record (EHR) system. Patient portals provide a secure website through which patients can access their clinical data. They are a key component of most EHR architectures and an important focus of meaningful use because of their potential to streamline the delivery of patient-centered health care. Features of patient portals may include secure messaging, after-visit summaries, medication lists, allergy lists, laboratory results, and appointment scheduling. When used effectively, patient portals can empower consumers by enabling active management of their own care. However, we know little about how patient portal use fits into the broader personal health information management (PHIM) practices of various groups, such as older adults.

Within the general U.S. population, there is considerable interest in patient portals. Nearly 80% of consumers participating in a 2008 Deloitte Survey of Health Consumers expressed interest in accessing an integrated medical record that provides information on personal test results, doctor visits, and hospital stays. Of those participants, 75% expressed a desire for online portals that facilitate appointment schedules, email communication with physicians, access to test results and medical records. Other research also shows similar findings with regard to interest in using online personal health records. However research about the usage patterns of various users, as well as the association between use of patient portals and quality of care and health outcomes, is sparse.
In particular, research evidence about PHRs and older adults is limited. Witry et al. examined views of family practice physicians and staff about the benefits, barriers, and use of PHRs by older adults, in relation to medication use. They concluded that the family practice physicians did not have a complete understanding of the benefits that PHRs can offer patients. Several studies highlight the challenges that older adults face when using PHRs, such as physical or cognitive limitations and low computer literacy. Providers have also raised concern that use of PHRs could introduce privacy risks to patients. Other providers worry that older adults may be especially vulnerable to “getting scammed” while using electronic or online PHRs.

These findings demonstrate providers’ hesitancy to promote the use of PHR among older patients, whom they see as susceptible to privacy violations. Security has been examined by Weitzman and colleagues in the context of personally controlled PHRs. By studying a PHR called Indivo, the researchers identified important concerns of older adults about a possible breach in security. Older participants felt they had “less to lose” than younger participants, if a security breach occurred. However, the same participants expressed worry that information disclosure through a PHR could impose an emotional burden on their family members.

Other researchers have focused on older adults’ use of PHRs for a range of functions, such as home medication management and information sharing with providers. For example, Kim et al. explored the use and utility of PHRs in a low-income population of older adults. The 33-month study involved 44 older adult residents of a federally funded housing facility. Researchers assessed use of and user satisfaction with a web-based PHR, the Personal Health Information Management System (PHIMS). Use among the residents was low, with only 13% of eligible residents using the system and, of those, about half used the system on only one occasion. This study concluded that the majority of the low-income elderly would not benefit from PHRs, due to poor technical skills, low health literacy and limited physical/cognitive abilities. Thus, older adults face considerable barriers in their adoption and use of PHRs and other information technology that could support PHIM. In addition, patient portal technologies have not been designed with consideration to older adults’ needs and preferences, which may explain why older adults have been slower to adopt these new technologies for managing personal health information.

Our SOARING project, a 5-year Agency for Healthcare Research and Quality (AHRQ) funded investigation, is designed to address this gap by establishing an understanding of the PHIM practices and needs of older adults. Based on Grounded Theory and the ecological framework of the Balance Theory, we sought to identify current health information practices and needs among older adults living in a variety of residential settings. Using focus groups, in-depth interviews with longitudinal follow-up, and participatory design with older adults and their key stakeholders, our goals are to develop older adult-centered guidelines to assist developers in the design of useful and usable health information management tools that better serve older adults.

We report here on our initial findings from semi-structured interviews concerning older adults’ use of patient portals for accessing and organizing health information.

**Methods**

**Recruitment**

As part of our larger SOARING study (http://www.nwphp.org/research/projects/current/health-information-management-older-adults), we conducted semi-structured interviews with older adults (≥ 60 years) to better understand how older adults manage their health information. We recruited participants from residential communities, assisted living facilities, and independent residences in King County, Washington. Recruitment efforts included presentations, flyers and key contacts at senior centers, community organizations, and older adult communities. We employed purposive sampling to ensure a diverse representation of age, gender, socio-economic status (SES), racial and ethnic backgrounds, across a range of living situations. With regard to diversity of living situation, for instance, we recruited several participants who were self-described as either currently homeless or recently homeless (n=3).
Inclusion criteria included age 60 years and older, the ability to read and speak English, and lack of cognitive impairment, measured by a score of 4 or higher on the 6-item screener to identify cognitive impairment. The University of Washington IRB approved all study procedures (IRB #45853).

Semi-structured interviews

We conducted semi-structured, 60-90 minute interviews with each participant. In most instances, interviews took place at a participant’s place of residence. After obtaining consent, we audio recorded the interview, photographed artifacts associated with PHIM, and made field notes. The interview session consisted of a demographic survey followed by a series of semi-structured questions concerning health and the use and organization of personal health information. Topics covered in the interview guide included: health conditions, management of health conditions, interactions with healthcare providers and corresponding materials received, health-related record keeping, health information seeking, and use of patient portals. Examples of specific questions include: Do you keep any records related to your health? What information (if any) do you keep track of to keep yourself healthy? What tools do you use to track your health information?

Initially, we asked participants to describe their general experience with technology and we did not focus on any specific technology or tools. However, over time, due to the frequency with which participants mentioned patient portals, we added structured and semi-structured questions regarding patient portals. In introducing this section of the interview, we described patient portals to participants as, “Websites used to access your health records or to communicate with your provider team.” Local examples of Epic MyChart and Cerner PHR were shared with participants. We probed with questions to explore barriers and facilitators to patient portal use among participants.

Analyses

Interview audio recordings were transcribed by a professional transcription service. Two research team members reviewed the transcripts and notes for discussions related to portal use. Demographic survey data were summarized with descriptive statistics using Microsoft Excel.

Results

Participants

Demographics: We interviewed 74 participants. Of those interviewed, 20% (15/74) reported using a patient portal, such as Epic MyChart™ (Epic Systems Corp, Verona, WI), to help manage their health information. Table 1 compares demographics of the 15 portal users with demographics of the remaining 59 participants who report not using a patient portal (“portal nonusers”). Portal users ranged in age from 61 to 93 years, and most lived independently in a private residence (60%) and had college education or higher (67%). Although portal nonusers were similar in age, fewer were college educated (53%) and more lived in retirement or assisted living facilities (74%). Whereas 28% of portal nonusers reported having an informal or unpaid caregiver, only 7% of portal users reported this. Eighty percent of the portal users identified themselves as white.

Note: Later in this section, we discuss a group of “potential portal users.” In this table, portal nonusers (n=59) include these twelve participants we later mention as potential portal users.

Technology use and experience: Our preliminary analysis found that most portal users (93%) reported using a computer 6-7 days per week and 47% rated themselves as “very experienced” computer users. All reported having learned to use a computer 10 or more years ago and having Internet access where they live. In contrast, the majority of portal nonusers reported having used computers less than 6 days per week (30%) or not at all (36%), 25% lacked Internet access where they lived, and 19% reported they had not learned to use a computer. Among the 52 participants (portal users and nonusers) who use computers, the most common use of computers was emailing and browsing the Internet.

From the interviews, two themes emerged with regard to patient portals: ‘facilitators,’ characteristics, uses or other attributes that encouraged or eased utilization of a patient portal, and ‘barriers,’ individual or systems level obstacles to patient portal use.

**Facilitators of portal use**

The majority of patient portal users made positive comments about the specific portal they used. Easy access to health information, more direct communication with providers, and the ability to make appointments online were cited as valued features.

Many (9 of 15) portal users mentioned ease of access to health information, as illustrated in the quotes below:

- *...they have the whole record there. That’s what I love about it.*
- *The doctor has email, and you can get the lab results from there. So anything I need to know, like, if I think my potassium is too low or something, I can check it and see.*

Direct communication with providers and the ability to easily make an appointment were cited as other positive features of patient portals:

- *You can email back and forth with your doctor if you don’t necessarily need an appointment.*
- *I like the fact that I could, rather than calling and running the risk of a note being taken wrong or misunderstanding what I said, it’s there. It’s in my own typing. It’s there. And I can send my doctor notes about my blood pressure, or ask her a quick question. I love computer medical technology.*
- *...it’s a faster and better way to communicate with my doctor about things. You see, before, the only way I could communicate with my doctor was call over to adult medicine and leave a message if I had to.*

From portal users, we heard many positive comments regarding the ease of use, such as:

- *...it’s been really good, and helpful, and easy to utilize. They made the system user friendly.*
I like that it is easy to access and easy to navigate.

*MyChart is really cool. ... I can make* an appointment online with my doctor. All my doctors there are listed. I just click on the one I want.

Regarding management of health information, several participants mentioned a dramatic reduction in their health information record keeping with portal use.

- I used to file things away in file folders, but now I pretty much just go check, and if I want to find out what my blood pressure’s been for the last five years, all I have to do is go online and they have these nice little lists.... So they made me kind of lazy really, as far as keeping other records. Because it’s right there.

**Barriers to portal use**

Potential portal users: Of the 59 nonusers, 20% (16% of the total participants interviewed) mentioned some relationship to patient portals. Four participants stated they had previously used a portal, three participants had use of a portal through a family member, and two participants indicated they would like to use a patient portal in the future.

Within this potential portal user group, problems with logging in were provided as reasons for no longer using patient portals:

- *Because I don’t use it all the time, I forget what the password is and what the user I.D. is.*

- I gotta make sure I still have my password and everything so I can get back on it.

Some of the potential portal users expressed positive attitudes towards patient portals, but cited the cost of maintaining internet access as a barrier to their use:

- The experience was great. If I had internet at home, if I could afford internet, I would definitely use MyChart on a regular basis.

- *But for many people, we cannot afford the internet. I can’t afford $29 a month.*

Portal Nonusers: Many of the remaining participants classified as portal non users had never heard of a patient portal and/or expressed negative attitudes towards the use of portals. Participants who did not use patient portals primarily cited personal reasons, such as general aversion to or difficulty using computers, and security concerns:

- My brain will only stand so much confuzzling.

- *I’m not interested [in patient portals]. I don’t like any of my things on the web or whatever you call it. I’m against all that.*

- *Well, I’m paranoid of computers. People get their identity, they find out their weaknesses, and they swoop in, and I really don’t feel like broadcasting all my stuff on the internet.*

Of note, factors intrinsic to specific patient portals, such as difficulty navigating a site or interface design, were not mentioned by any participants.
Discussion

Over the last twenty years, there has been growing emphasis on the involvement of health consumers in their own healthcare. Important to the success of the consumer health movement is accurate, accessible, and understandable health information to assist with treatment and health decisions. Older adults are the largest consumers of health care and expend the greatest proportion of US health care dollars. Thus, their participation is key to the success of this consumer movement towards greater health autonomy.

Despite reported barriers to the use of PHR technologies by others\textsuperscript{16, 17}, 20% of the older adults we interviewed use patient portals to manage their personal health information. These participants express enthusiasm about the access to health information, direct communication with providers, and ease of scheduling that patient portals offer. These factors appear to serve as important facilitators for adoption of patient portals by older adults.

Our finding that those older adults who use patient portals do so because the use of the portal facilitates efficient and easy access to health information, medical reports, and clinical appointments, is consistent with prior studies investigating older adult adoption of new technologies, such as automated teller cards and cell phones\textsuperscript{18, 19}. These studies indicate that older adults generally lag behind younger adults in adopting new technologies\textsuperscript{16, 17}, but will adopt new technologies when they feel these technologies enhance convenience, are useful to their daily lives, and are easy to use\textsuperscript{21, 22}. An important insight our study adds to prior work is that patient portals appear to play a small but substantial role in facilitating PHIM in older adults.

As in prior research, we identified several barriers to the use of patient portals by older adults. Our results indicate that these barriers are not only limited to the individual end user level, such as computer knowledge or prior training, but also exist at a systemic level, including infrastructure that hinders Internet access and lack of resources within residential facilities to equip residents with tools that facilitate access.

Despite the promising insights our findings offer, generalizability is limited due to the small number of older adults living in King County, Washington. Although a sizeable proportion of participants we engaged used patient portals, this proportion and its composition could differ in other geographic locations. Portal users in our study were highly educated and lived independently, which complements groups of older adults in prior studies\textsuperscript{9}. It is not clear the extent to which portal use may result from or promote independent living. Expanded studies are needed to determine the general penetration of patient portals in this population, factors that contribute to portal use by older adults, and associations between patient portal use and independent living.

Our findings provide initial insights into the PHIM needs and practices of older adults regarding patient portals. Further research is needed to better understand what factors related to form (mobile phones, tablets, desktop computers) and function are most important to include in patient portals when designing user interfaces that facilitate management of personal health information by older adults. A better understanding of the role of caregivers in portal use will be the focus of future studies involving interviews we will conduct with key stakeholders. By establishing an understanding of the PHIM practices and needs of older adults, we can substantially inform the design of supportive technologies and promote the adoption of patient portals by this important population.

Conclusion

Despite broader issues of accessibility, such as computer use and Internet access, study findings highlight the small but substantial role of patient portals as a platform to facilitate management of personal health information among older adults. The use of patient portals demonstrates their growing potential and role in helping older adults maintain...
the health, wellness, and independence they desire. Design features based on consideration of needs and practices of older adults will facilitate appeal and maximize usability, which are critical to adoption.

Abstract

The standard of safe medication practice requires strict observance of the five rights of medication administration: the right patient, drug, time, dose, and route. Despite adherence to these guidelines, medication errors remain a public health concern that has generated health policies and hospital processes that leverage automation and computerization to reduce these errors. Bar code, RFID, biometrics and pharmacy automation technologies have been demonstrated in literature to decrease the incidence of medication errors by minimizing human factors involved in the process. Despite evidence suggesting the effectiveness of these technologies, adoption rates and trends vary across hospital systems. The objective of study is to examine the state and adoption trends of automatic identification and data capture (AIDC) methods and pharmacy automation technologies in U.S. hospitals. A retrospective descriptive analysis of survey data from the HIMSS Analytics® Database was done, demonstrating an optimistic growth in the adoption of these patient safety solutions.

Introduction

In 1999, the Institute of Medicine estimated that the hospital mortality rate due to medication errors is as much as 98,000 patients per year, thereby making these errors a major public health concern. In their report, the committee recognized that addressing patient safety is the key component for the delivery of quality healthcare. It recommended improvements that have to be made in hospital systems and processes to reduce injuries. Different safety systems support the five rights of medication administration (right patient, right drug, right time, right dose, and right route) at various steps of the medication administration process. While electronic health record systems and computerized physician order entry are primarily focused on preventing order errors in the prescribing, transcribing and documentation steps, additional errors can transpire in the dispensing, and administering phases. It is estimated that the majority of medication errors occurs at the prescribing (49%) and administration (26%) steps.

The years following the IOM report exhibited some small but insufficient progress in addressing medication errors through changes in health systems and policies. In 2004, the U.S. Food and Drug Administration (FDA) initiated a ruling to require all human medications and biological product labels to contain barcodes to help prevent medication errors and avert costs related to these adverse events. In 2012, as additional support to the FDA ruling, the Centers for Medicare & Medicaid Services (CMS) required hospitals to begin tracking medications starting from when a medication order is initiated, until its administration to the patient. The CMS measures suggest the implementation of assistive technologies such as automatic identification and data capture (AIDC) methods like barcoding, radio frequency identification (RFID) and biometrics in conjunction with pharmacy automation technologies like automated dispensing machines, carousels, and robotics, as part of Stage 2 Meaningful Use Core Measures.

Various AIDC methods have been demonstrated in literature to be effective in the reduction of medication errors and other adverse events. Barcode technology is used in various departments and processes in the hospital such as the laboratory, pharmacy, radiology, and medication administration. The technology typically uses a handheld barcode reader that registers and documents events of contact between medication, equipment, and healthcare personnel. Bar code medication administration (BCMA) is an integral part of preventing medication errors by making sure that the right patient is receiving the right medication at the point of administration. It is reported that BCMA systems have reduced the incidence of medication errors by more than 50%, and the risk of adverse drug events by 11% or approximately 20 events per day. The use of BCMA is also required in a closed-loop medication administration environment, which is the primary criteria for Stage 5 of the Healthcare Information and Management Systems Society (HIMSS) EMR Adoption Model (EMRAM), in addition to various levels of EMR system capabilities. It requires an electronic medication administration record (eMAR) that uses an AIDC method, which is integrated with the...
computerized provider order entry (CPOE) and pharmacy information systems. A closed-loop environment significantly reduces medication errors, and increases patient identity confirmation before medication administration17.

Bar code systems have also been applied to hospital laboratory processes. In neonatal intensive care units (NICU), barcoding in breast milk administration has been used to ensure that fragile, hospitalized infants who are separated from their mothers receive the right expressed milk at the right time from the right parent, eliminating the risk of transmitting infectious diseases caused by human immunodeficiency virus, cytomegalovirus, and hepatitis B virus16-21. Barcoding has also been used to reduce adverse events and errors from the transfusion of blood products, which is estimated to occur once every 12,000 units transfused in the United States. Over 50% of the mortality from transfusion-related injuries is attributed to errors in patient verification22-24. Implementation of barcoding for transfusion verification has been demonstrated to be effective in preventing mismatched transfusions that may lead to the transmission of HIV, hepatitis B/C, and severe reactions such as acute hemolysis from ABO incompatibility24-26.

RFID technology has also been used in hospitals for the same purposes as barcodes. The technology uses radio waves for collecting and transferring patient data25. Some of its advantages over barcode technology include the elimination of the “line-of-sight” requirements of barcode scanners, and the capability to program RFID devices. RFID has been demonstrated to be effective in supporting patient safety, eliminating medication errors, and other adverse events related to patient misidentification28-30.

Other newer technologies enhance patient safety by providing patient security through identity verification systems that use biometrics. Biometrics are measurable characteristics of human beings that are unique to each individual. Biometric devices and their accompanying software in healthcare institutions permit the automatic authentication of patient and provider identity for different purposes such as secure EHR system access, and patient verification31. The most common hospital implementation of biometrics are the use of fingerprint and iris scanning32, 33. The unique authentication methods of biometrics make it difficult to mismatch and forge identities since no two irises or fingerprints are the same.

In the pharmacy, different hardware systems that work in conjunction with hospital information systems play a major role in assuring that the right drug, the right dosage and instructions are prepared for the right patient. Automated dispensing machines (ADM), or automated dispensing cabinets are the most commonly used devices for decentralized medication dispensing34. These machines are storage devices that automate and track medication distribution at the point-of-care. ADMs have been shown in the literature to have a moderate effect in reducing medication errors by automating the dispensing process34, 35. Carousels on the other hand are centralized medication storage and retrieval systems designed as a series of revolving shelves set on rails has been seen to reduce filling or dispensing errors by automating medication dispensing in the pharmacy36. Lastly, stationary robotic compounding and dispensing systems that work in conjunction with ADMs and carousels to further increase the accuracy of dispensing the correct drugs, dosage and quantities to the right patients, have demonstrated clear benefits in patient medication safety37. These pharmacy automation technologies all use a form of AIDC method to verify that medication orders are correctly linked to patient records, and monitor inventory supplies.

Motivated by the important role and potential that AIDC methods and pharmacy automation implementations possess in reducing medication errors, we aimed to determine the state and trends of adoption of these technologies in U.S. hospitals using a retrospective descriptive analysis of survey data from the HIMSS Analytics® Database
Methods

Data Source

Data from the Healthcare Information and Management Systems Society (HIMSS) Analytics® Database was used in this study. The HIMSS Analytics® Database contains survey data on the use, implementation and planning status of health IT hardware, software and infrastructure of more than 5,400 non-federal U.S. hospitals, which is included in its catalogue of nearly 40,000 U.S. healthcare facilities. The database is noted to be the “most comprehensive database” for hospital IT adoption, representing nearly all non-federal hospitals with greater than 100 beds, and more than 90% of all U.S. hospitals. The annually updated database originally started as the Dorenfest 3000+ Database in 1986, and was integrated in 1998 with data from U.S. Integrated Health Delivery Systems, to form the Dorenfest IHDS+ Database. It was then acquired by HIMSS Analytics, a non-profit subsidiary of HIMSS, in 2004 to become the HIMSS Analytics® Database. The latest version of the database used in this study contains data for 2012, which was made available at no charge to academic researchers in July, 2014.

Measurement of Technology Adoption

The HIMSS Analytics® Database was used to explore specific data elements pertaining to AIDC and pharmacy automation technology users. In each data element, survey respondents indicated whether the technology is currently being used, with some elements containing information on plans for future adoption. The following hierarchy tree loosely represents the availability and organization of the database relating to the topic of interest. The HIMSS survey definition of each data element can be found in Appendix A.

I. Barcoding
   A. Laboratory Department
      • Breast Milk Administration
      • Transfusion Verification
   B. Pharmacy Department
   C. Radiology Department
   D. Medication Administration
      • Complete Closed-Loop Medication Administration

II. Radio-frequency Identification (RFID)
   A. Laboratory Department
   B. Pharmacy Department
   C. Radiology Department
   D. Medication Administration

III. Medication Administration Processes

IV. Biometrics
   A. Fingerprint Scanning
   B. Iris Scanning

V. Pharmacy Automation
   A. Automated Dispensing Machines (ADMs)
   B. Carousels
   C. Robotics

Data Analysis

The Microsoft Access files of the HIMSS Analytics® Database, from 2008 to 2012, were queried using SQL from inside an R script. The R script gathered the results of the SQL queries, assembled together the data from separate years, and exported Office Open XML spreadsheets (XLSX files). All source code used in this paper is available for free reuse, commentary and contribution at http://github.com/fabkury/itsos. Exploratory analyses were done to inspect the technology adoption rates in U.S. hospitals. Hospitals with missing values were not considered in the analysis of each data element individually.
Results

Barcoding Use

Bar code medication administration (BCMA) had the highest growth in adoption, averaging an increase of about 7% per year from 2008 to 2012 compared to 6.4%, 2.2%, and 1.15% for Pharmacy, Laboratory, and Radiology departments respectively (Figure 1). Barcoding use in the Laboratory department had the highest hospital adoption at 84.2% in 2012, compared to 73.9%, 58.1%, and 50.8% for Pharmacy, medication administration, and Radiology respectively. Within hospitals that use barcoding in the Laboratory (n=4509), 7% (n=324) use the technology for transfusion verification, while only 2% (n=89) use it in breast milk administration in 2012. In the same year, within hospitals that use BCMA (n=3114), 67.8% (n=2110) attest to having a complete closed-loop medication administration system, while 12.3% (n=384) indicate that they do not, and 19.9% failed to provide the detail. Table 1 includes a summary of adoption rates for bar coding, and Figure 1 for annual trends.

RFID Use

RFID medication administration had the highest growth in adoption, averaging an increase of about 0.4% per year from 2008 to 2012 compared to 0.25%, 0.24%, and 0.14 for Laboratory, Pharmacy and Radiology departments respectively (Figure 2). Similarly, RFID medication administration had the highest adoption rate in 2012 at 1.87% compared to 1.57%, 1.55%, and 1.12% for Laboratory, Pharmacy and Radiology departments respectively. A summary of the adoption rates is shown in Table 1.

Medication Administration Process

For all hospitals in 2012 that either use bar code or RFID in their medication administration process (n=2901), 97.1% (n=2818) of the hospitals have tags on the medications, 89.4% (n=2594) have them on their patients, and 59.2% (n=1718) on nurses. Patient tagging had the highest growth in adoption per year at 3.4%, followed by nurse (3.38%) and medication (0.96%) tagging and from 2008 – 2012 (Figure 3).

Biometrics

The use of fingerprint scanning had an average annual adoption increase of 1.23% per year from 2008, leading to a total of 15.9% (n=871) adoption within all hospital respondents (n=5467) in 2012. Iris scanning technology has an average annual adoption rate of 0.02% from the same time frame, and is only currently being used in 13 hospitals (0.02%) in 2012. Only 2.49% (n=136) hospitals in 2012 plan to expand or adopt the fingerprint technology in the following years, in contrast to only 12 hospitals (0.22%) for iris scanning.

Pharmacy Automation

The adoption of automated dispensing machines increased at an average annual adoption rate of 2.08% from 2008, leading up to an 81% hospital use in 2012. ADMs are predominantly used in the Medical or Surgical departments, followed by the Emergency department and the operating rooms (Figure 4). In contrast, robotic technology average annual adoption rate is around 0.04% within the same 4-year timeframe, leading to 7.88% hospital use in 2012. Carousel hospital use increased from 2.9% in 2010 to 5.67% in 2012. About 20.32% of hospitals that are already using carousels plan to expand and acquire more.

</table>
Discussion

Overall, we found that from 2008 to 2012, medication administration had the highest annual growth rate for both bar code (7%) and RFID (0.4%) technologies. This may be due to healthcare legislation such as the HITECH Act in 2009, which stimulated investments in health IT, and set deadlines to meet specific meaningful use criteria. The data also shows that about 67.8% of hospitals with BCMA have a closed-loop system. This raises the optimism for more hospitals to reach Stage 5 of the HIMSS EMRAM.

Bar code adoption in laboratory (84.2%) and pharmacy (73.9%) departments in 2012 are high, which may be attributed to regulations by the FDA, and the amount of inventory tracking inherent in both departments. We also notice the low adoption rates for breast milk administration and transfusion verification, which may be attributed to the relatively low error rates compared to general medication administration, and the lack of consensus and economic resource. Adoption of RFID technology is also generally low, which is consistent with previous studies explaining costs and negative perceptions as major barriers of implementation.

Details on the utilization of bar code and RFID tags on patients, medications, and nurses in 2012 show both high rates for medications (97.1%) and patient (89.4%) tags, but moderate use for nurses (59.2%). This may have implications on the requirements of closed-loop medication administration and information in the eMAR because a record containing the identity of the healthcare provider who dispenses and administers the medication is important in tracking and record transparency.

For biometrics use in hospitals, the data shows a slower annual adoption of both fingerprint and iris scanning technologies (1.23% and 0.02% respectively), with comparatively low overall adoption. Low adoption may be due to the costs in implementing biometrics within existing EHR systems and workflows. Pharmacy automation technologies such as ADMs seems to show a steady growth (2.8%), with high hospital adoption (81%) in 2012. In contrast, adoption is relatively low for carousels and robotics (5.67% and 7.88% respectively), which is most likely due to the hardware costs.

In summary, although the benefits of AIDC methods and pharmacy automation technologies in reducing medication errors seem to be increasing, current adoption trends, careful consideration of individual hospital systems, costs, and clinical workflow should guide administrative decisions leading to greater adoption. Organizational leadership and the cooperation of hospital staff will continue to be important in the ongoing adoption of these technologies. Findings from this study may provide decision makers with a benchmark for strategic planning and deployment of these technologies for raising the quality of healthcare through the improvement of patient medication safety.
Limitations
The main limitations of the HIMSS Analytics® Database are similar to other studies based on data from surveys. The data relies on accurate self-reporting from hospital administrators via completion of a phone interview and an IT inventory survey. Survey respondents who represent their healthcare institution may not have the information to answer some specific parts of survey questions, or may decline to volunteer the information, leading to varying response rates for each data element. Some data elements lack more granularity and other specific process details that may open new opportunities for research and analyses. In common with many surveys, the time period during data collection may not accurately reflect the current state of affairs in these organizations.

Regardless of its limitations, to our knowledge, the HIMSS Analytics® Database is currently the most complete survey of health IT adoption and implementation in nearly all non-federal U.S. hospitals. It is a valuable resource that continues to be refined and expanded every year, providing researchers with trends that contribute to more strategic hospital investments and planning.

Conclusion
The increasing adoption of AIDC methods and pharmacy automation technologies across all U.S. hospitals sizes demonstrates interest in ensuring patient medication safety towards the improvement of quality of care. A comprehensive knowledge of the adoption rates, trends and evidence demonstrating the effects of implementing these technologies may contribute to individual hospitals’ strategic decision-making. The database provided by HIMSS Analytics™ with the support of the Dorenfest Institute are capable of providing analytic data on these and other matters that may serve as indicators for healthcare access and delivery. The same knowledge may stimulate the development of future health policies supporting the five rights of medication administration.

Acknowledgement
We gratefully acknowledge HIMSS Analytics™ for access to the data, especially Jennifer Horowitz (Senior Director of Research) of HIMSS North America for her valuable assistance with the database. This research was supported by the Intramural Research Program of the National Institutes of Health (NIH), National Library of Medicine (NLM) and Lister Hill National Center for Biomedical Communications (LHNCBC). This research was also supported in part by an appointment to the NLM Research Participation Program, administered by the Oak Ridge Institute for Science and Education (ORISE) through an interagency agreement between the US Department of Energy (DoE) and the NLM.

Towards a Generalizable Time Expression Model for Temporal Reasoning in Clinical Notes

Sumithra Velupillai, PhD1,2, Danielle L. Mowery, PhD2, Samir Abdelrahman, PhD2,3, Lee Christensen, MS2, Wendy W Chapman, PhD2

Abstract

Accurate temporal identification and normalization is imperative for many biomedical and clinical tasks such as generating timelines and identifying phenotypes. A major natural language processing challenge is developing and evaluating a generalizable temporal modeling approach that performs well across corpora and institutions. Our long-term goal is to create such a model. We initiate our work on reaching this goal by focusing on temporal expression (TIMEX3) identification. We present a systematic approach to 1) generalize existing solutions for automated TIMEX3 span detection, and 2) assess similarities and differences by various instantiations of TIMEX3 models applied on separate clinical corpora. When evaluated on the 2012 i2b2 and the 2015 Clinical TempEval challenge corpora, our conclusion is that our approach is successful – we achieve competitive results for automated classification, and we identify similarities and differences in TIMEX3 modeling that will be informative in the development of a simplified, general temporal model.

Introduction

Accurate temporal identification and normalization is imperative for many biomedical and clinical tasks including generating timelines1, identifying phenotypes2, and creating problem lists3. Natural language processing (NLP) can help enrich event, phenotype, and problem detection by providing temporal context to event descriptions extracted from clinical texts. A major NLP challenge is developing and evaluating a generalizable temporal modeling approach that performs well across corpora and institutions. Few NLP system studies evaluate the generalizability of clinical temporal models and information extraction approaches that were developed for a particular use case or institution. To date, several NLP community challenges - 2015 Clinical TempEval4, based on the THYME corpus5, 2012 i2b26, and the 2014 ShARe/CLEF eHealth challenges7 - have attempted to encourage benchmarking and system evaluation for temporal extraction by applying adapted versions of the TimeML model8 to clinical texts of various report types from different institutions (Beth Israel Deaconess Medical Center, Partner’s Healthcare, and Mayo Clinic). The TimeML model enables automated temporal reasoning from text by defining a number of components, of which three components are central: events (e.g., diseases), time expressions (TIMEX3s, e.g., dates), and time relations (e.g. disease after date). Through this, it is possible to order events in time with respect to each other, and with respect to time expressions in the texts. Correctly identifying time expressions within a temporal reasoning system is necessary to capture specific mentions of time, and thus enable time anchoring and positioning of relevant events from narratives. These community challenges have established the state-of-the-art performance for NLP identification of these three core components in the adapted TimeML models.

For temporal modeling, overall performance has been published for each community challenge; however, there are few studies reporting system performance across different clinical corpora, and there has not been any in-depth analysis of performance on different temporal model subtypes. Our long-term goal is to create a generalizable temporal reasoning model that leverages and simplifies existing models. We initiate our work on reaching this goal by focusing only on TIMEX3 identification. In particular, we present a systematic approach to 1) generalize existing solutions for automated TIMEX3 span detection, and 2) assess similarities and differences in different instantiations of TIMEX3 models applied on different clinical corpora.

In the aforementioned challenges, successful approaches for TIMEX3 span detection, that is, correctly identifying and extracting specific mentions of time expressions in text such as “tomorrow”, “14 April 1998”, “for two weeks”, have either employed rule-based systems or machine learning approaches using lexical and syntactic features in combination with rule-based information. In the 2012 i2b2 challenge, the top performing approaches resulted in F1 scores between 0.8-0.91 for overlapping TIMEX3 spans9. The results in the 2014 ShARe/CLEF eHealth challenge
were lower: 0.37 overlap F1 \textsuperscript{1}. Our research lab, the Biomedical Language Understanding Laboratory (BluLab), recently participated in the 2015 Clinical TempEval challenge\textsuperscript{2}. Similar to other successful, high-performing NLP approaches, we developed a machine learning approach using local contextual features and information from a rule-based system to identify TIMEX3 spans. Our team ranked first on the TIMEX3 span detection task in this challenge, resulting in an overall exact F1 of 0.72. However, official scores in these challenges only report overall results for TIMEX3 detection. Moreover, to our knowledge, there are few studies reporting system performance across different clinical corpora, along with an in-depth analysis of similarities and differences in TIMEX3 annotations.

Methods
We performed our study on two corpora\textsuperscript{1}: the 2015 Clinical TempEval corpus, and the 2012 i2b2 challenge corpus. The Clinical TempEval corpus was created within the THYME project\textsuperscript{3} consisting of 440 clinical notes and pathology reports for colon cancer patients from the Mayo clinic (in total 293 documents for training, 147 for test). The i2b2 corpus consists of 310 discharge summaries (190 training, 120 test) from Partners Healthcare and the Beth Israel Deaconess Medical Center. We chose these two corpora for this study because they employ similar, but not identical, temporal models, and were specifically developed for temporal reasoning evaluation. Three main steps were employed: 1) TIMEX3 model mapping, with the aim of generating a common, comparable model, 2) state-of-the-art TIMEX3 classification assessment, with the aim of evaluating top performing TIMEX3 system approaches across corpora, and 3) qualitative error analysis, feature ablation evaluation and TIMEX3 type characterization, with the aim of completing an in-depth analysis.

Common TIMEX3 type model
In our attempt to characterize and analyze similarities and differences in separate instantiations of TIMEX3 models applied on different corpora, the first step was to create a common TIMEX3 type model. The two corpora employ slightly different TIMEX3 definitions and types. The Clinical TempEval corpus contains six TIMEX3 types: DATE, TIME, DURATION, PREPOSTEXP, QUANTIFIER and SET, in contrast to the i2b2 corpus which defines four types: DATE, TIME, DURATION and FREQUENCY. To enable comparison and analysis, we map the more fine-grained Clinical TempEval TIMEX3 types to the i2b2 types in the following way: PREPOSTEXP annotations are merged to DATE, and QUANTIFIER and SET annotations are merged to FREQUENCY. Examples are provided in Table 1. For our experiments, we maintained the training and test splits from each respective challenge corpus.

Time expression extraction using ClearTK
To generalize existing solutions for automated TIMEX3 span detection, we applied the top-performing TIMEX3 span detection approach from the 2015 Clinical TempEval challenge\textsuperscript{9}. This is a UIMA-based machine learning solution using the ClearTK framework\textsuperscript{10}. A separate support vector machine (SVM: Liblinear) sequence label classifier (CleartkSequenceAnnotator) was created for each TIMEX3 type, where parameter setting (C-value) was determined by a grid search on a subset of the training data and set manually on the final model. The data was preprocessed with cTAKES v. 3.2 to extract lexical, morphological, and syntactic features\textsuperscript{11}. For the TIMEX3 types, gazetteer information specific to each type was also added as features, based on an adapted version of HeidelTime\textsuperscript{12}. A Begin-Inside-Outside chunking representation was used, with the following features: the current token, the current token with the two last characters stripped (\textit{decades} \rightarrow \textit{decad}), part-of-speech tag, numeric type (e.g. \textit{digit},

\textsuperscript{1} University of Utah Institutional Review Board approval was obtained for using these corpora for research
alphanumeric), capital type (e.g. all in upper case, mixed case), lower case, context tokens\(^2\), and whether or not the token is found in the TIMEX3 type-specific gazetteer. Compared to the successful approaches in the 2012 i2b2 challenge that used machine learning, this approach is similar, but not identical – for instance, Xu et al.\(^3\) employed the conditional random fields (CRF) algorithm and slightly different features. Roberts et al.\(^4\) used CRF for TIMEX3 boundary detection and SVM for type classification. Most other solutions were entirely rule-based\(^5\).

Three SVM models were trained using the datasets: 1) i2b2 training data, 2) Clinical TempEval training data, and 3), merged model with the two training data sets combined. System performance was evaluated on the i2b2 test data and the Clinical TempEval test data releases, using exact and overlapping precision, recall, and F1 as main outcome measures. We used the official evaluation script provided in the 2015 Clinical TempEval challenge\(^6\).

**Qualitative error analysis, feature ablation evaluation and TIMEX3 type characterization**

A qualitative error analysis to identify commonalities and differences was performed. We analyzed true positives on the results obtained by training a model on one corpus and evaluating on the other, to identify commonalities between the corpora and to characterize “core” TIMEX3 types. We also analyzed false positives and negatives, to identify and characterize differences between the annotations. Error analysis was performed on exact match only. Additionally, we performed a feature ablation study on the results obtained by this training/testing setup as well as on the results obtained when training a merged model with both corpora, evaluated on each test set. We built separate models with one feature removed each time, to identify which features seem to contribute the most for this task (i.e., if results are worse when removing one feature compared to using all features, this is an indication of an important feature).

**Results**

We present classification results on the i2b2 and Clinical TempEval test sets and results from the qualitative error analysis. First, we evaluate performance on within-corpus models. Second, we analyze performance on the two test sets on applied on the model trained on 1) i2b2 training data, 2) Clinical TempEval training data, and 3) merged training data. Finally, we present results from the qualitative error analysis, feature ablation evaluation and TIMEX3 type characterization, using the outputs from applying each test set on the model created from the other corpus’ training data. Overall corpus statistics are presented in Table 2.

**Temporal Information Extraction using ClearTK**

In Table 3, classification results on the two test datasets when applied on the model built from their corresponding training data are shown, strict and overlap. Results for the majority TIMEX3 type DATE are best overall. Results for DURATION and FREQUENCY are considerably higher when using overlapping evaluation criteria, in particular for DURATION, from 0.60 to 0.76 F1 for i2b2, and from 0.47 to 0.70 for Clinical TempEval. Precision is considerably higher for FREQUENCY when using overlapping evaluation, from 0.71 to 0.84 for i2b2 and 0.56 to 0.78 for Clinical TempEval. Results for the least frequent TIMEX3 type TIME differ between the corpora: for the

</tbody>
</table>

To further analyze differences and commonalities, the two test sets were also evaluated on all three created models. The least frequent TIMEX3 type (TIME) is not included since the number of training instances is insufficient. Not surprisingly, results are worst when applying each test set on the model created from the other corpus (e.g. training on Clinical TempEval and testing on i2b2), Figure 1. Specifically, results for DATE drop from 0.79 strict F1 (0.88 overlap F1) to 0.53 (0.61) on the i2b2 corpus, and from 0.79 (0.86) to 0.44 (0.57) on the Clinical TempEval corpus. For DURATION and FREQUENCY, the drop is from 0.60 (0.76) to 0.23 (0.44) and 0.56 (0.66) to 0.11 (0.18) on the i2b2 corpus. On the Clinical TempEval corpus, the drop is from 0.47 (0.70) to 0.31 (0.53) for DURATION and from 0.35 (0.49) to 0.06 (0.10) for FREQUENCY. Moreover, creating a merged model from the two training sets did not improve overall results for either test set (0.69 overall span strict F1 when evaluated on the i2b2 test set, and 0.69 when evaluated on the Clinical TempEval test set). However, results for DURATION on the Clinical TempEval test set are slightly improved when applied on the merged model (0.51 strict F1, 0.76 overlap).

Figure 1. Classification results per TIMEX3 type DATE, DURATION and FREQUENCY, strict and overlap. Three models: i2b2 model, Clinical TempEval (CTE) model, and merged (the two training sets combined) model, each evaluated on the i2b2 and CTE test sets.
**Qualitative error analysis, feature ablation evaluation and TIMEX3 type characterization**

We perform a qualitative error analysis on true positives, false negatives, and false positives (exact match) from the system output of each test set applied on the model created from the other corpus’ training data. This way, we are able to characterize corpus-specific annotations, and also commonalities between the two corpora.

**Figure 2.** Venn diagram depicting error types and examples for each test set, based on system predictions for the i2b2 test set applied on the model built on the Clinical TempEval training data, and vice versa.

Most true positives on both test sets for DATE cover explicit dates such as “9 November, 2010”. These are also the most common DATE annotations in both corpora. However, DATE annotations such as “today”, “this time”, “many years ago”, “the same time” are also correctly classified in both test sets. For DURATION and FREQUENCY, common annotations include expressions like “several years” and “every x hours”. Examples are given in **Figure 2**.

However, the differences outweigh the commonalities between the corpora, as evidenced by the results. The Clinical TempEval DATE annotations contain a larger number of pre-/post-operative expressions that are not covered in the i2b2 corpus, as well as relative DATE instances such as “recent” and “now”. The i2b2 corpus, on the other hand, contains more DATE expressions typical for the document type (discharge summaries), such as “day of life x”, “hospital day x”, “day of delivery”, “day of transfer”, “the time of discharge”, that are not covered in the TempEval model. This is reflected also in the false positive results: when evaluating the i2b2 test data annotations on the Clinical TempEval model, expressions such as “currently”, “recent”, “intraoperatively”, “the future”, “the time”, “that time” are erroneously predicted as DATEs.

For DURATION, the i2b2 corpus contains expressions such as “>48 hours”, “the entire night”, “one months time”, “overnight”, “the next several hospital days” that are missed by the Clinical TempEval model, while the i2b2 model fails to represent Clinical TempEval DURATION annotations such as “quite a few years”, “a while”, “lifelong”, “overnight”.

1256
The i2b2 FREQUENCY annotations contain expressions not covered in the Clinical TempEval model, such as “q24”, “QID”, “qhs”, “bid”, “x 1”, while expressions such as “per day” and “xx/min” are common in the Clinical TempEval FREQUENCY annotations.

In addition to the lexical variations in the two corpora, the feature ablation analysis reveals that surrounding words are the most informative feature for all TIMEX3 types both when evaluating a trained model built on one corpus using the other test set, and when evaluating the merged model on each test set, Table 4. All other features have limited individual impact overall.

Table 4. Feature ablation study for error analysis. Each feature was removed when building the TIMEX3 model, keeping all remaining features. Results are presented for the TIMEX3 types DATE, DURATION and FREQUENCY, once when building a model on one corpus (Clinical TempEval (CTE) or i2b2) and evaluating on the other (cross-corpus), and once when building a model with both training sets (merged).

Discussion and Conclusion

In this study, we present a systematic, simplistic, and scalable approach to 1) generalize existing solutions for automated TIMEX3 span detection, and 2) assess similarities and differences in different instantiations of TIMEX3 models applied on different clinical corpora.

Retraining and applying the top-performing TIMEX3 span detection solution from the 2015 Clinical TempEval challenge on the i2b2 corpus produces competitive results: 0.74 strict F1 and 0.87 overlapping F1. The top ten performing systems in the 2012 i2b2 challenge resulted in strict F1 between 0.67-0.80 and overlapping F1 between 0.8-0.91. Combining the two training data sets to create a merged model slightly decreases overall results when evaluating on each test set, but results for DURATION on the Clinical TempEval test set are improved, indicating that the addition of new training data from a different corpus was informative.

Enabling characterization and analysis of commonalities and differences between different time expression instantiations by evaluating system output errors from a model trained on one corpus and evaluating on another is informative. In particular, this method reveals that some TIMEX3 expressions can be accurately covered across the two corpora, in particular for the majority type DATE. The main differences between the studied corpora can be categorized into two types: lexical (and document-type specific) variants (e.g. “qid”) and structural (document type). Further, the feature ablation study sheds light on the informativeness of individual features, where surrounding tokens provide context that is clearly crucial for improved performance.

Rule-based systems were successful in the TIMEX3 span extraction subtask of the 2012 i2b2 challenge. Such systems generally produce high recall, while machine learning-based systems generally produce high precision results. Given the new knowledge about lexical variants for different TIMEX3 types in different corpora, we also want to study how to incorporate this information and how to best make use of a combination approach for all elements needed in a temporal reasoning solution.

---

4 results for strict matching were recalculated using the official 2012 i2b2 evaluation script on system submission outputs provided by the challenge organizers
Contributions and limitations

The main contribution of our approach is that it is systematic and simple in acquiring and building a high-performing task model for TIMEX3 classification. Moreover, our results do not necessarily depend on the system approach for TIMEX3 detection - one could choose to apply any of the previous successful machine learning-based approaches for comparison or further development. Second, we achieve competitive results for automated classification on a new corpus. Third, we identify similarities and differences in TIMEX3 modeling which could be informative in the development of a simplified, general temporal model. Finally, our in-depth analysis identifies lexical variants of time expressions that could be useful for several clinical information extraction use-cases and feature engineering. However, we are planning to tackle the following potential future points:

Our proposed approach is evaluated only on two corpora annotated with similar temporal models. Other models have been proposed for the clinical narrative domain, such as the Temporal Constraint Structure\textsuperscript{15}. Applying our proposed approach on this model would probably require more mapping steps, as well as access to annotated documents for system development and assessment. An alternative approach to our mapping strategy could be to keep more granular types separate and build hierarchical structures (e.g. PREPOSTEXP is-a DATE) instead of mapping to broad TIMEX3 types – this way, one would get a richer representation while still keeping a generalizable overall model.

Document structure information, such as sections, is not taken into consideration when mapping annotations or for the feature engineering of the machine learning models, which is a central part of clinical narratives. We plan to incorporate this information in future extensions.

Our analysis of commonalities and differences is performed only on exact matched expressions: a richer overall picture would be obtained if also studying overlapping annotations. For successful unification of annotations, more training data, hierarchical ontologies, and annotation layers are needed, in particular for a more accurate and detailed analysis and model of less frequent types, such as FREQUENCY and TIME. The feature ablation study reveals that surrounding words are the most informative features. We intend to further study the impact of different context window sizes, and also whether the contextual information could be de-lexicalized in some way, to address generalizability across document types.

We will continue our work on developing a simplified, common temporal reasoning model for core elements needed in a full-scale temporal reasoning system. As a first step, we will employ our suggested approach on other available annotated corpora for further analysis and development. In particular, we plan to use the 2014 ShARE/CLEF eHealth corpus that contains disorder mention annotations along with semantic attributes, including time expression annotations. Since this corpus was created with a focus on disorder annotations, not overall temporal information, we expect that our proposed approach will have high coverage on extracting relevant time expressions, but that tailoring will be necessary for disorder context. We will also extend our work to include temporal expression normalization, as well as event span and attribute classification, and temporal relations.

Acknowledgements

We thank the Mayo clinic and the challenge organizers for providing access to the 2015 Clinical TempEval corpus, and i2b2 and the 2012 challenge organizers for providing access to their corpus. Organizational Uses of Health Information Exchange to Change Cost and Utilization Outcomes: A Typology from a Multi-Site Qualitative Analysis

Joshua R Vest, PhD, MPH1 and Erika Abramson, MD, MS1,2

1Division of Health Policy and Economics, Department of Healthcare Policy and Research, Weill Cornell Medical College, New York NY; 2Department of Pediatrics, Weill Cornell Medical College, New York, NY

ABSTRACT

Health information exchange (HIE) systems facilitate access to patient information for a variety of health care organizations, end users, and clinical and organizational goals. While a complex intervention, organizations’ usage of HIE is often conceptualized and measured narrowly. We sought to provide greater specificity to the concept of HIE as an intervention by formulating a typology of organizational HIE usage. We interviewed representatives of a regional health information organization and health care organizations actively using HIE information to change patient utilization and costs. The resultant typology includes three dimensions: user role, usage initiation, and patient set. This approach to categorizing how health care organizations are actually applying HIE information to clinical and business tasks provides greater clarity about HIE as an intervention and helps elucidate the conceptual linkage between HIE and organizational and patient outcomes.

INTRODUCTION

Health information exchange (HIE) is the electronic sharing of patient information between different health care organizations and providers.[1] Through HIE, physicians, clinical staff, and administrative users have access to patients’ tests, reports, encounters, and summary documents from other providers. Improved access to more comprehensive information may support decision-making, inform providers of additional medications or allergies, and help avoid repeated or duplicate testing.[2] The literature on the effectiveness of HIE is mixed,[3,4] but several evaluations have suggested HIE usage can help avoid unnecessary utilization[5,6] and reduce health care utilization and costs.[7-9] These evaluations tend to either view HIE as a structural capability of the health care organization,[e.g. 10,11,12] or examine the effects of accessing HIE systems in a specific clinical context.[e.g. 5,7,9] The use case underlying many of these evaluations is that HIE fills in the gaps in patient information for clinicians.[2,13]

However, HIE is a much more complex intervention in the daily operation and practices of health care organizations. For example, the use cases for HIE extend to non-clinical staff in health care organizations, such as case managers or social workers, and HIE can support non-clinical functions.[14] Also, conceptualizing HIE activity as a uniform structural resource for an organization obscures much of the variation in information access and usage. Users of HIE systems retrieve and receive different types of information[15] and in different formats (e.g. reports, push messages, or online queries).[16] Furthermore, integrating information from HIE into clinical care or business processes requires more steps than is reflected by basic measures of system access.[17] With all these known variations, how organizations actually put HIE delivered information to use to improve patient outcomes and reduce costs is not well defined.

We sought to provide greater specificity to the concept of HIE as an intervention to change cost and utilization outcomes. While evaluations according to the availability or access of HIE systems have been insightful, they do not capture how individuals and health organizations actually act upon HIE information or integrate HIE into existing workflows and clinical practices. Using qualitative methods, we examined the basic question, how are organizations using the community-wide patient information made available through HIE? To answer this question, we developed a typology of the organizational applications of HIE. This typology provides greater clarity about HIE as an intervention and facilitates the conceptual linkage of this technological intervention to patient outcomes and organizational changes.
METHODS

We selected a qualitative approach to capture the variety of potential patient populations, clinical care settings, work processes, and applications of HIE.

Study site
All data were collected from health care organizations working with the Bronx Regional Health Information Organization (RHIO) in New York. The RHIO is a non-profit organization that facilitates HIE for more than 60 inpatient and ambulatory care organizations and includes information on more than 550,000 patients. The Bronx RHIO was established in 2005 and offers notification alerts of patient utilization, DIRECT messaging, a portal to query patient information, a centralized data repository for analytics, electronic referral management, and analytic services.[18] In 2012, the Bronx RHIO was awarded a CMS Health Care Innovation Award to develop data registries and expand analytic capabilities in order to reduce the cost of care for Medicaid and Medicare patients in the borough. This expansion of services makes the Bronx RHIO an ideal setting for a typology development as it resulted in a large and diverse number of activities supported by HIE. As part of the grant, the Bronx RHIO customizes services for each participant through collaborative consolation, so that HIE information supports each organization’s specific portfolio of services or interventions. This analysis was conducted as part of broader evaluation that includes a quantitative evaluation of impact and costs.

Selection of participants
We conducted interviews with 25 health care organization leaders, clinicians and employees, as well as representatives from the Bronx RHIO from June 2014 to March 2015. Interviewees had titles such as: CMIO, Section Chief, Director, Nurse, Case Manager, Physician, Statistician, and Patient Navigator. A total of 5 organizations were included. We purposefully sought interviewees who were knowledgeable about the organization’s work with the Bronx RHIO, users of information obtained by HIE, and who were participating in the Bronx RHIO’s current CMS supported HIE activities. Bronx RHIO staff identified the key contacts and the key contacts helped to identify the relevant individuals within the organization. Consent was obtained from each individual interviewee. Interviews also occurred opportunistically during the data collection process. Recruitment stopped once all community partners using HIE to support their activities were represented and thematic saturation had been reached. All interviews were audio recorded and transcribed.

Interviews
Interviews followed a semi-structured format with open-ended questions. The interview guide asked about the characteristics of the organization and specifics about the activities (including day to day activities, interventions or projects) supported by HIE. Questions about the role of HIE in these activities were guided by the Triangle Model for evaluating health information technology interventions, which considers technology usage as the product of patient, provider, technology and organization interaction.[19] Data collection occurred through a combination of on-site (72%) and telephone interviews. Interviews lasted an average of 33 minutes.

Interviews occurred in three distinct steps. First, we conducted a focus group with representatives of the Bronx RHIO to obtain an overview of all partner activities. The focus group included a group card-sorting activity, where the respondents were asked to group the partners’ activities according to: 1) project goals; 2) how information is accessed; 3) who accesses the information; and 4) no set criteria (free choice). Next, we interviewed the leadership of the participating health care organizations. Interviews occurred only after the organization was actively applying HIE to an activity (i.e. the site had “gone live”). Organizations were active once they: 1) established procedures and policies for Bronx RHIO information usage; 2) HIE information was being accessed as part of the activity; and 3) HIE information had been applied in the delivery of health care services to patients. Finally, we interviewed those individuals using HIE information or involved in the activities supported by HIE. This approach limited our sample to active users and excluded any organization planning or simply “piloting” HIE usage.

Analysis
The first objective with our qualitative analysis was to develop a typology of HIE usage. We did not select any particular theoretical lens for analyzing the data, but instead followed an iterative, general inductive and comparative approach.[20] First, through a joint reading of three transcripts and review of the card sorting exercise, we identified preliminary themes relevant to defining our typology using open coding. Subsequently, we coded all transcripts together during joint reading sessions, continually checking, revisiting, and adjusting our typology in light of
additional data. As a member check, we reviewed our typology with Bronx RHIO representatives and other HIE evaluators. The second objective was to identify any factors that acted as barriers or enablers of successful usage of HIE. During interviews, we did not formally define success, but for our analyses we defined success solely as a reported application of HIE to meet a goal or job requirement. Therefore, success was both self-reported and could vary between job types and organizations. Determinants of success were identified concurrently during our analysis using an open coding approach. Through discussion and regular meeting sessions, synonymous codes were merged and we grouped each identified theme into the broader categories of determinants suggested by the Triangle Model (i.e. axial coding). Data analysis used NVivo10. The study was approved by the Weill Cornell Medical College Institutional Review Board.

RESULTS

Interviewees represented specialty care centers at an integrated hospital system, a hospital emergency department, a federally qualified health center (FQHC), and a case management organization. We identified 12 examples of different applications of HIE during interviews (Table 1). Some instances of usage were repeated across the organizations (e.g. most had staff authorized to access the Bronx RHIO’s standalone web-based portal). However, other organizational activities were supported by reports consisting of line lists of patients or by automatic notifications of patient emergency department utilization and hospital admissions.

Typology

Our typology includes three independent dimensions: USER ROLE, USAGE INITIATION, and PATIENT SET (see Figure 1 on the next page). The typology is applied at the level of the application of HIE in the context of a specific program or activity.

The primary, and most distinguishing, characteristic of each of the organizational applications of HIE was the USER ROLE. Formally, we defined the dimension as the “ultimate consumer of the information.” The USER ROLE dimension does not necessarily measure the individual who interacted with the HIE systems, but instead the focus is on the individual within the organization who was expected to act upon the information or for whom the information was supposed to support their work. This distinction reflects the features we observed during interviews. First, information obtained via HIE could have been delivered to an intended user in any fashion (e.g. a portal, notification, or report). Second, the HIE information may effectively pass through many different hands on the way to the “ultimate consumer” (e.g. proxy users, or analysts who produce reports to give to other staff). We subdivided USER ROLE into two categories. Clinical users included all physicians, nurses, and case managers applying HIE information to direct patient care. Administrative users were managers, analysts, and staff not engaged in clinical care.
The second dimension of the typology describes how information was obtained from HIE. Instead of focusing a specific type of technology used (e.g. DIRECT compared to a portal), we focused on a larger concept: who was responsible for obtaining the information for the end user or who initiates usage (i.e. USAGE INITIATION)? In our sample, the organizations either relied on the Bronx RHIO staff to provide the information in a form for use by end users (i.e. externally generated) or the responsibility for ensuring end users had access to information was managed internally. For example, the Bronx RHIO staff would electronically send a detailed report of their clients’ recent emergency encounters and utilization history. To the organization, the information was created externally. In contrast, some organizations utilized staff and resources to generate similar reports or to query the centralized data repository for patient information. As a case in point, one nurse case manager reported she relied on the Hospital’s statistician “to generate that list of potential [clients]” for her. These were instances of internally initiated access to HIE information.

The final dimension, PATIENT SET, refers to the type of patient to whom the information is being applied. Organizations were applying HIE information to two broad types of patients. First, they were using HIE to find information on a pre-defined set of patients, in other words on patients that were already seeking ongoing care from the organization. Generally, these patients were selected subsets of the entire patient populations defined by a specific clinical condition (e.g. diabetes, asthma, etc.) or by utilization levels (e.g. frequent emergency department users). For example, the FQHC was using HIE information to identify which of their existing diabetes patients were out of date on laboratory testing. The Health System applied HIE in a similar fashion by generating line listings of their geriatric and asthma clinic patients’ recent emergency department visits and admissions. Alternative to using HIE to find information about existing patients was applying a set of criteria in order to find patients for inclusion in program or intervention. The criteria for finding patients was often a specific condition or response to a type of event. As an example of this type of patient finding, one organization used HIE to identify patients to include in their medical home and another used HIE to supplement missing demographic data in order to contact individuals recommended by the state Medicaid program for care management. As a third example, the Hospital and Health System used HIE to identify patients that had been recently discharged without usual sources of care to recruit for their care management or outpatient programs.

Determinants of successful application of HIE
As noted, all organizations were actively using HIE information within the organization. The degree of success was both varied and dependent upon multiple factors. ORGANIZATIONAL FACTORS, such as available resources, established procedures, and dedicated staff, were supportive for both administrative and clinical users. For example, the Health System queried the central data repository to generate a “lost to follow up report” to identify patients recently discharged who had not been seen at their specialty clinics. To act on this information, the Health System had dedicated staff and a “call center does exist, and they can and do respond to orders to make those calls.”

Figure 1. Multi-dimensional typology of organizational applications of health information exchange (HIE)
Likewise, for clinical users, the FQHC structured work processes so that information retrieval from HIE was the responsibility of medical assistants and not other clinicians. As another example, the Case Management organization has staff and procedure in place to respond to any automated notifications that are received after normal business hours.

Generally, the application of HIE fit better into administrative workflows than for PROVIDERS. Physicians and nurse practitioners were not often active users of the query-based HIE, and HIE information was more likely to get in front of clinical users if work practices made sure the information was delivered to them or if another user queried databases on their behalf. For physicians, there was variable utility in knowing about recent discharges or emergency department visits. However, administrative users could use even a small bit of information (such as a telephone number), and even outside the context of a patient visit, to perform outreach or other activities. There was generally more certainty that the administrators would act on the information than clinicians. For example, as a manager noted, “I can control the [administrative staff]. They work for me. The doctors don’t…”

PATIENT FACTORS could inhibit the effectiveness of the organization’s application of HIE. As an example, each morning clinicians in specialty clinics serving diabetic and asthmatic patients were provided lists of the recent emergency encounters and admissions for that day’s scheduled patients. Clinicians found that information useful, but the utility of the information was limited because “my no show rate is so high that many of those patients on that report probably don't show up for their appointments.” In particular, asthma patients were not inclined to follow up with a visit after an emergency department encounter because their symptoms were controlled or their acute needs had already been addressed. In contrast, the show rate for geriatric patients was much higher and as a result the information from HIE was “a great tool.” This may be due to the fact that geriatric patients tended to be quite loyal to their primary care providers who were coordinating the entirety of their care.

Unsurprisingly, lack of integration between HIE TECHNOLOGY and other systems was often viewed as a barrier to usage. This was most noted for query-based HIE, because none of the organizations had a single sign on option within their electronic health record (EHR). As a result, usage of query-based HIE suffered. As one interviewee noted: “I don't actually go to the [portal] because it's very cumbersome….I mean, so how does it fit into my day? It doesn't fit into my day. …” In contrast, internally initiated reports from the centralized analytics database by report writers or data analysts fit much better into workflows. Likewise, interviewees reported alert notifications and aggregated reports created by the Bronx RHIO fit easily into workflows and were much easier approaches to use HIE information.

Finally, patient CONSENT was a recurring theme in our interviews and was consistently a barrier. New York State policy requires active patient consent and that consent be obtained at each site. Clinical and administrative users were unable to access information they believed they needed for unconsented patients. Organizations varied in their approaches to dealing with the challenge of consent, but most tried to incorporate the consent paperwork as part of the registration process. The FQHC had a community health worker on site (funded by the Bronx RHIO) solely to consent and educate patients. This approach was particularly successful, because it coupled a culturally competent representative with technology and a standardized work process. If the community health worker could not obtain patient consent, the clinician was notified within the EHR to also try to obtain consent.

LIMITATIONS

This typology and the factors identified with HIE usage are limited by several factors. First, our findings are based on a single RHIO’s line of services. However, the number of services offered by the RHIO is broad and to a diverse set of health care organizations. Furthermore, these services are consistent with our broader experiences with other HIE-facilitating organizations. Second, it is possible to conceptualize organization’s application of HIE on additional dimensions not represented in our typology. For example, our typology does not include the information content, which has been applied in prior HIE studies of usage. We choose to keep the number of dimensions limited to make it more manageable and easier to apply generally. Also, the relevance of clinical and demographic information as a distinguishing feature of usage is not always clear. Both are often needed and both are often present from any type of usage of HIE (i.e. push and pull systems both provide access to clinical and demographic information). Likewise, the Triangle Model proved to be a useful approach for categorizing themes identified from different care settings, but it is possible that basing our interview guide on an alternative framework would have resulted in additional determinants. Additionally, our typology reflects organizational activity relatively early in the
course of their HIE usage, as such we did not observe all possible combinations of our USER ROLE – INITIATES
USAGE - PATIENT SET typology (as some may not occur frequently). We plan on conducting a second wave of
interviews to better understand how HIE activities evolve over time. Lastly, we did not independently assess or
define successful use of HIE, but let the interviewees define what they viewed as a “successful application of HIE.”

DISCUSSION

Based on interviews with those facilitating HIE activities and health care professionals using HIE services, we
developed a three dimensional typology of organizational use of HIE. Each instance of an organization’s application
of HIE can be categorized according to the type of USER ROLE (clinical or administrative), the USAGE INITIATION
(internally or external), and the PATIENT SET (pre-defined patients or patients to be found). This approach to
categorizing how health care organizations are actually applying HIE information to clinical and business tasks
provides greater clarity about HIE as an intervention and helps elucidate the conceptual linkage between HIE an
organizational and patient outcomes.

Importantly, this study and the resulting typology, illustrates the broad set of possible applications of HIE to health
care organizations. Generally, HIE has been conceptualized and evaluated as a clinical intervention. As
reported here, HIE supported direct clinical care, but also case management activities and patient enrollment into
specific programs. These additional use cases are of potential value to health care organizations and also illustrate
the diverse types of users associated with HIE. Other evaluations have noted that HIE is used by more than just
physicians, but this typology helps explain the broader purposes and activities of these non-clinical users. In
similar fashion, the typology highlights the unique role HIE can fulfill for health care organizations: as a source of
information on the unfamiliar, hard to reach, and sought out type of patient. Each interviewee had multiple
information systems supplied by their organization or even partner entities (like the state Medicaid agency). Once
those sources had been exhausted, interviewees were turning to HIE to fulfill their information needs.

Considering how organizations actually apply HIE to the care of their patients may help explain many of the current
research findings and can provide guidance to future studies. For example, several evaluations have viewed HIE
from the adoption / implementation perspective by measuring HIE simply as present or absent. This is a perfectly
valid approach and very much in line with the idea of information systems as structural component of the
organization, but findings from the literature using this measurement approach are mixed. Our
typology can help move measurement a step closer to actual processes. Instead of measuring HIE as a structural
feature only, our typology characterizes and clarifies the underlying processes organizations use to apply the
information obtained via HIE. This potential tighter coupling could help better inform the types of outcomes we
should expect from HIE interventions and also suggests considering potential organizational and operational
outcomes in addition to the utilization outcomes which are the focus of most of the existing research. For example,
organizations obtaining regular HIE reports containing information on new patients to enroll in a program clearly
fits expectations of efficiency and productivity gains. While these are important gains, it would be hard pressed to
expect quick changes to patient care and quality from such a usage strategy. Alternatively, changes to care
utilization and cost reduction might be more logical for clinical users with on-demand access to information working
to intervene on a set of pre-defined high-risk patients. Both use cases have a value and utility for a high performing,
cost conscious organization. However, these potential impact of administrative and clinical HIE use cases most
likely will not be reflected in the same dependent variables.

For health care managers, the immediate impact of adoption HIE might be most quickly realized in administrative,
patient finding projects. For one, the risk of non-acceptance of technology tends to run higher among clinicians and
physicians in particular. Second, implementing reports or queries into administrative workflow might be easier.
Third, this type of usage does not require the level of resources or staffing necessary to, for example, mount an
effective case management program to respond to notification alerts. Importantly, as the instances of usage
described in this study illustrate, administrative usage requires minimal information like addresses or telephone
numbers to be effective in reaching previously lost patients. If the patients were truly lost to follow up or impossible
to reach with existing information, any additional patient finding using HIE information is a gain that would not be
realized otherwise. Although not a particularly exciting use case, the 30 day readmission reduction program and
population health approaches like Accountable Care Organizations have heightened the importance of this basic
activity. Administrative use cases may not necessarily be what health information technology advocates and health
reforms hope for from HIE, but it is a start. It then becomes incumbent on the organization and the HIE facilitating
organization to make sure that HIE does not get regulated to only as a back-office application, but that the clinical use cases are adopted as well.

Finally, this study reiterates that health care organizations and the usage of health information technology are still subject to the influences of the external environment. In this study, patient consent was a barrier to effective usage. These policies governing the rules and requirements for obtaining patient consent are outside of health care organizations’ or the RHIO’s direct control. In New York State, consent policies are set statewide and developed through a collaborative process facilitated by the New York eHealth Collaborative and includes the State Department of Health, provider representatives and the public.[24,25] Organizations facing externally defined constraints have basically three broad options. The first is to try to address the challenge internally by shifting work process to meet the externally defined expectations. The Bronx RHIO’s funding of onsite staff and organizations building in the consent process into workflows were effectively this approach. The goal of both of these approaches was only to mitigate the perceived challenges dictated by the environment, e.g. New York’s active consent policy places responsibility for consent on the RHIOs, but the actual operationalization of the consent process occurs within health organizations. A second option is to attempt to change the external environment. Health care organizations in states with opt-in policies face workflow challenges and have to expend resources on a process that a) is the benefit of the patient and b) is a burden that their competitors and colleagues in opt-out states do not have to absorb. Health care organizations in states with opt-in policies that are serious about HIE a valuable part of their technology strategy should engage health policy makers to facilitate access to necessary information in a way that still meets patients expectations for privacy. Health policy makers should be willing to work with health care organizations on this issue, because the risk is if they don’t health care organizations will adopt the third potential response to external pressure: HIE just won’t be used.

CONCLUSION

Our study creates a novel typology for characterizing how health care organizations are actually applying HIE information to clinical and administrative tasks. Our typology consists of three distinct dimensions: USER ROLE, USAGE INITIATION, and PATIENT SET. Use of this typology can help support future evaluations and implementations by focusing on the distinct role of the information obtained from HIE plays in activities desired to improve organizational and patient outcomes.

ACKNOWLEDGEMENTS

We thank the interviewees and their respective organizations for their time and cooperation. Also, we thank Drs. Rainu Kaushal, Lisa Kern, and Zachary Grinspan for their insights and assistance. Abstract

Data driven technology is believed to be a promising technique for transforming the current status of healthcare. Electronic Health Records (EHR) is one of the main carriers for conducting the data driven healthcare research, where the goal is to derive insights from healthcare data and utilize such insights to improve the quality of care delivery. Due to the progression nature of human disease, one important aspect for analyzing healthcare data is temporality, which suggests the temporal relationships among different healthcare events and how their values evolve over time. Sequential pattern mining is a popular tool to extract time-invariant patterns from discrete sequences and has been applied in analyzing EHR before. However, due to the complexity of EHR, those approaches usually suffers from the pattern explosion problem, which means that a huge number of patterns will be detected with improper setting of the support threshold. To address this challenge, in this paper, we develop a novel representation, namely the temporal graph, for event sequences like EHR, wherein the nodes are medical events and the edges indicate the temporal relationships among those events in patient EHRs. Based on the temporal graph representation, we further develop an approach for temporal signature identification to identify the most significant and interpretable graph bases as temporal signatures, and the expressing coefficients can be treated as the embeddings of the patients in such temporal signature space. Our temporal signature identification framework is also flexible to incorporate semi-supervised/supervised information. We validate our framework on two real-world tasks. One is predicting the onset risk of heart failure. The other is predicting the risk of heart failure related hospitalization for patients with COPD pre-condition. Our results show that the prediction performance in both tasks can be improved by the proposed approaches.

1 Introduction

Patient Electronic Health Records (EHRs) [6] is one of the major carriers for conducting data driven healthcare research. There are various challenges if we work directly with EHRs, such as sparsity, noisiness, heterogeneity, bias, etc [5]. One important aspect for mining EHR is how to explore the temporal relationships among different medical events within patient EHRs. Many approaches have been proposed for temporal mining of EHRs. For example, Lasko et al. [11] proposed a deep learning method for obtaining patterns from lab value signals. Kale et al. [7] applied deep learning to discover the physiomes from the physiological streams obtained in Pediatric Intensive Care Unit (PICU). Zhou et al. [24] proposed an optimization based technology for discovering the feature groups within which the raw medical features have similar evolving patterns. For all these works, the authors either identified as some evolving pattern on the values of a specific medical feature (e.g., lab test or physiological stream), or a group of medical features (e.g., diagnosis, medication or both). Another important type of feature is the temporal pattern across different medical features, which is referred to as temporal signatures in this paper. The existing approaches on temporal signature identification are mostly based on sequential pattern mining [2, 18] or temporal abstraction [17, 19, 20]. One major challenge for these methodologies working on EHRs is pattern explosion, which is the phenomenon that too many patterns are identified from the patient EMR corpus with improper support threshold. One could try to solve this problem by increasing the support threshold value used by sequential pattern mining but the mined signatures are then typically trivial. Therefore there is an urgent need on an effective way to identify a reasonable number of clinical meaningful signatures.

One cause of pattern explosion for traditional approaches is the sequence based representation: lots of the time the
finest time granularity of patient EHR is day, within each day many events can happen. This generates a huge number
of sequential patterns when the support threshold is relatively lower [2, 18]. In this paper, we propose a novel graph
based representation for patient EHRs. We represent the EHRs of every patient as a graph. The nodes in the graph are
the medical events (i.e., diagnosis, medications, lab tests, etc.). The edges indicate the temporal relationships among
the events in the EHRs of the corresponding patient. Every edge points from an event to another event that took place
later in time. A weight will also be associated with each edge, which encodes the average duration between the two
events in EHRs. A bases learning framework is then developed to identify the bases that can be used to compose all
those temporal graphs. We present several concrete instantiations of such framework and validate its effectiveness on
a real-world EHR data warehouse both quantitatively and qualitatively.

It is worthwhile to highlight the following aspects of the proposed graph based framework:

- Comparing to the traditional sequence based representation, temporal graph is more compact, which makes the
downstream analytics procedure more efficient.
- With graph based representation, the detected signatures are subgraphs instead of subsequences. Each subgraph
is composed of a set of subsequences. This effectively alleviates the pattern explosion problem while at the
same time retains the interpretability of the mined signatures.
- We provide concrete instantiation examples of the proposed framework in a completely unsupervised scenario,
as well as in scenarios where we incorporate expertise knowledge as regularizers.
- The framework is validated on a real-world EHR data warehouse with two specific clinical scenarios. One
is early detection of Congestive Heart Failure (CHF). The other is hospital readmission prediction of CHF
patients with Chronic Obstructive Pulmonary Disease (COPD) pre-conditions. We showed that the prediction
performance can be improved with the mined temporal signatures.

2 Related Work

This section reviews the existing work that are closely related to the research proposed in this paper. One is electronic
phenotyping approaches. The other is temporal knowledge extraction.

2.1 Electronic Phenotyping

Electronic phenotyping refers to the process of identifying phenotypes from patient EHRs, which is the procedure of
extracting clinically relevant features. There are quite a few existing electronic phenotyping works. For example, Ho
et al. [3, 4] formulates the patient EHRs as tensors, wherein every mode represents a specific type of medical event.
The entries in the tensor encode the interaction of those features (e.g., the frequency of a medication and a primary
diagnosis). Then they proposed a tensor factorization based approach for identification of the phenotypes. Zhou et al.
[24] formulates EHRs as temporal matrices with medical events as one dimension and time as the other dimension.
They propose an optimization based technology for discovering the phenotypes within which the raw medical features
have similar time-evolving patterns. Lasko et al. [11] proposed a deep learning method for obtaining phenotypes
from continuous lab value signals, where they first adopted Gaussian process regression to impute the missing lab test
values. Kale et al. [7] applied deep learning to discover the physiomes from the physiological streams obtained in
Pediatric Intensive Care Unit (PICU). For all these works, they either define a phenotype as some evolving pattern on
the values of a specific medical feature (e.g., lab test or physiological stream), or a group of medical features (e.g.,
diagnosis, medication or both). They did not consider the temporal relationships across different medical events, which
could be crucial as they suggest important information on the impending disease conditions.

2.2 Temporal Knowledge Representation

Knowledge representation from temporal data is a hot research topic in both data analytics and biomedical infor-
matics. For continuous time data, one popular approach is to transform them into discrete symbolic representations
(string, nominal, categorical, and item sets). Popular approaches include Piecewise Linear Approximation (PLA) [10], Adaptive Piecewise Constant Approximation (APCA) [8], Symbolic Aggregate approXimation (SAX) [13], Piecewise Aggregate Approximation (PAA) [9], etc. One can refer to [13] for a survey on these approaches.

For discrete time data, Mörchen et al. [15, 16] proposed the Time Series Knowledge Representation (TSKR) as a pattern language (grammar) for temporal knowledge discovery from multivariate time series and symbolic interval data, where the temporal knowledge representation is in the form of symbolic languages and grammars that have been formulated as a means to perform intelligent reasoning and inference from time-dependent event sequences. More recently, Wang et al. [22] proposed a convolutional framework to extract temporal signatures in discrete time data using the Temporal Event Matrix Representation (TEMR), which is shown to have wide applicability to a variety of data and application domains that involve large-scale longitudinal data.

The temporal graph we propose in this paper provides an alternative way to represent the temporal knowledge contained in discrete time data. The temporal graphs capture temporal structures hidden in the sequences in a more compact way, where the nodes in the graph are events appeared in the EHR and the directed edges encode the temporal relationships between pairwise events. In this representation, the events missing in patient EHRs will not appear in the graph, and the repeated pairwise events with the same ordering will only appear once in the graph. With this representation, the temporal graph is robust and resistant to sparse, noisy, and irregular observations. Moreover, this representation is very intuitive to interpret the temporal relationships among different medical events in patient EHRs. Another advantage is that with graph based representation, the detected phenotypes (or patterns) will also be in the form of graphs, which can be viewed as a nature aggregation of sequential patterns. In this way, we can effectively alleviate the pattern explosion problem.

3 Methodology

In this section we will introduce the details of our temporal graph based framework for phenotype identification from patient EHRs. First we present the basic definition of temporal graph and how it is constructed.

3.1 Temporal graph construction

Suppose we have a set of event sequences $S = \{s_n : n = 1, \cdots, N\}$ where $N$ is the number of sequences. Each event sequence is denoted by $s_n = ((x_{nl}, t_{nl}) : l = 1, \cdots, L_n)$ where $L_n$ is the length of $s_n$. In other words, we observe event $x_{nl}$ at time $t_{nl}$ in the sequence $s_n$. We order the events $x_{nl} \in \{1, \cdots, M\}$ so that $t_{np} \leq t_{nq}$, for all $p < q$. Figure 1 illustrates an example of such graph.

With the observed event sequences, we construct the following temporal graph for each sequence $s_n$:

**Definition 1 (Temporal graph)** The temporal graph $G^n$ of sequence $s_n$ is a directed and weighted graph with our event set as its node set $\{1, \cdots, M\}$, where the weight of the edge from node $i$ to node $j$ is defined as

$$W^n_{ij} = \frac{1}{L_n} \sum_{1 \leq p \leq q \leq L_n} \left[ x_{np} = i \land x_{nq} = j \right] \kappa \left( t_{nq} - t_{np} \right),$$

where $\kappa(\cdot)$ is a non-increasing function.
\[ \kappa(\cdot) \text{ is a non-increasing function defined as follows, thus the closer event } i \text{ and event } j \text{ appear in } s_n, \text{ the higher } W_{ij}^n \text{ will be.} \]

\[
\kappa(\delta) = \begin{cases} 
\exp(-\delta/r) & \delta \leq \Delta \\
0 & \delta > \Delta 
\end{cases}
\] (2)

Here \( \Delta \) is a time horizon so that we only create an edge between a pair of events if the duration between them is smaller than or equal to \( \Delta \). \( r \) controls the locality of the edge computation in the temporal graph. Namely, a larger \( r \) captures the similarities among events in a longer temporal range, which potentially increase the connectivity of the temporal graph, while a small \( r \) only considers closely adjacent symbols as similar. In the extreme case when \( r \) approaches infinity, \( W^n \) becomes an almost constant matrix, since all appearing event pairs will be fully and equally connected.

The right part of Figure 1 provides a graphical illustration of the event sequence on the left part. In the sequence, we have 5 observations of 4 unique events. We show the duration between pairwise events. In this example, we use \( \Delta = 3 \) months and \( r = 5 \) days.

In our empirical study on real-world EHR data warehouse, we optimize \( r \) based on the algorithm performance in specific applications.

### 3.2 Temporal Signature Identification

With all the constructed temporal graphs, we want to identify the temporal signatures that can be used to best explain the observations. Our idea is to compute the graph bases as the temporal signatures which can be used to reconstruct the observed temporal graphs. In Figure 2, we have one simplified example, where we have three graph bases, and one observed graph can be expressed as the average of the first two bases. In practice, we do not know the bases at the beginning, and our temporal signature identification problem is exactly the process identifying the unknown graph bases with the observed temporal graphs.

We call the resultant graph bases as temporal phenotypes, which capture evolving patterns of the health conditions hidden in the event sequences. To be specific, suppose we have constructed the temporal graph \( G^n \) for each sequence \( s_n \), and \( G^n \) is associated with the adjacency weight matrix \( W^n \in \mathbb{R}^{M \times M} \). To reconstruct \( G^n \), we assume there are \( K \) graph bases \( B^k \in \mathbb{R}^{M \times M} \) for \( k = 1, 2, \cdots, K \), which can be used to approximate the adjacency matrix \( W^n \):

\[
W^n = \sum_{k=1}^{K} A_{nk} B^k,
\]

where \( A \in \mathbb{R}^{N \times K} \) is the matrix of reconstruction coefficients. To compute the optimal graph bases and the reconstruction coefficients, we minimize the total reconstruction error:

\[
\mathcal{J}(A, B) = \frac{1}{2} \sum_{n=1}^{N} \| W^n - \sum_{k=1}^{K} A_{nk} B^k \|_F^2,
\] (3)

where \( \| \cdot \|_F \) is the matrix Frobenius norm.

To make the solutions more interpretable, we also consider two constraints on the reconstruction coefficients in \( A \) and the graph bases \( B^k \) for \( k = 1, 2, \cdots, K \). The first constraint is about the non-negativity, i.e., \( B^k \succeq 0 \) for all \( k \),
since our original temporal graphs are non-negative. The second constraint requires $A \geq 0$ and $\sum_k A_{nk} = 1$, for $n = 1, \cdots, N$, which make the rows of $A$ to be valid multinomial distribution. In this way, we can quantify each patient by the temporal signatures with probabilities which can be in turn used for personalized medicine, patient segmentation, and disease diagnosis.

### 3.3 Regularization

As we introduced earlier, the reconstruction coefficients in $A$ can be used for various applications. In particular, for the medical diagnosis application, our goal is to derive informative features to improve the diagnosis performance, i.e., the classification of control/case groups for the patients. To this end, we extend the temporal signature identification for temporal graphs with regularization $\Omega(A) \geq 0$:

$$J(A, B) = \frac{1}{2} \sum_{n=1}^{N} \| W^n - \sum_{k=1}^{K} A_{nk} B^k \|_F^2 + \lambda \Omega(A),$$

where $\lambda \geq 0$ is the parameter controlling the degree of regularization. In the following, we propose several regularizations as $\Omega(A)$ to incorporate additional knowledge on the patients under study.

#### 3.3.1 Similarity based regularization

In the first case, we may have implicit similarity links between patients indicating they are from the same group (case or control). We can encourage the linked patients to have similar signatures in $A$ using the following regularization:

$$\Omega(A) = \frac{1}{2} \sum_{n_1, n_2} \frac{1}{2} \| A_{n_1} - A_{n_2} \|^2 S_{n_1 n_2},$$

where $S \in \mathbb{R}^{N \times N} > 0$ is symmetric matrix encoding the similarity information. Note that, when $S$ is asymmetric, we can just equivalently replace $S$ with $(S + S^T)/2$ without changing $\Omega(A)$. It follows that $S_{n_1 n_2} = S_{n_2 n_1}$ and

$$\Omega(A) = \frac{1}{2} \text{tr}(A' L A),$$

where $L = D - S$ and $D$ is the diagonal degree matrix such that $D_{nn} = \sum_{n'} S_{nn'}$. Note that, some rows/columns of $S$ may be completely zero if we do not have knowledge about the corresponding patients, e.g., the instances in the test set.

#### 3.3.2 Model based regularization

In the second case, we may have access to the group information of the patients. We let $Y_n = 1$ if the $n$-th patient is from the case group and $Y_n = -1$ if the patient is from the control group. With the explicit label information, we can define the regularization $\Omega(A)$ directly with a discriminative model $Pr(A_n, Y_n|H)$:

$$\Omega(A) = - \frac{1}{|\mathcal{L}|} \sum_{n \in \mathcal{L}} \log Pr(A_n, Y_n|H),$$

which is termed as average log-loss in the literature. Here, $\mathcal{L}$ is the training set where we have label $Y_n$ for $n \in \mathcal{L}$.

One particular choice for the discriminative model we can use for the case/control classification of patients is the logistic regression:

$$Pr(A_n, Y_n|H) = \frac{1}{1 + \exp(-Y_n f(A_n))},$$

where the linear model $H : A_n \mapsto f(A_n) = A_n \Theta + \theta$ and $(\Theta, \theta)$ are parameters in the model $H$. It follows that

$$\log Pr(A_n, Y_n|H) = - \log(1 + \exp(-Y_n f(A_n))).$$

1273
In addition to the log-loss for probabilistic model, other loss terms can also be used with the linear model $H$. We consider the hinge loss for $(A_n, Y_n)$:

$$\text{loss}(A_n, Y_n | H) = \max\{0, 1 - Y_n f(A_n)\},$$

and

$$\Omega(A) = \frac{1}{|C|} \sum_{n \in C} \text{loss}(A_n, Y_n | H). \quad (7)$$

The details on how to solve the optimization problem can be referred to [14].

4 Empirical Evaluation

In this section, we evaluate the effectiveness of our temporal signature identification approach on real-world patient Electronic Health Record (EHR) data warehouse, which includes the records of 319,650 patients over 4 years. We use the diagnosis information of the first three digits of ICD-9 (which stands for International Classification of Disease, 9th Version) code and the medication information in terms of drug ingredients to construct the EHR sequences. The temporal graphs are constructed from those sequences according to Definition 1. We will study the following two specific problems:

Hospitalization Prediction. We identify a set of 430 Congestive Heart Failure (CHF) patients with Chronic Obstructive Pulmonary Disease (COPD) pre-condition. Among them 100 are hospitalized within one year after CHF confirmation, the rest 330 patients are not. The goal is to make use of the records 360 days prior to the CHF confirmation date to predict whether the patients will be hospitalized or not within one year after CHF confirmation. The graphical illustration of this setting is in Figure 3 (a).

Disease Early Prediction. We first identify a set of 1127 case patients who are confirmed with Congestive Heart Failure (CHF), and then construct a set of 3850 group matched controls. For every patient, we set an operation criterion date, which is the CHF confirmation date for case patients, the day of the last record in our database for control patients. We then trace back from the operation criterion date, hold off the records within the prediction window (180 days), and use the records in observation window (360 days) for analysis. The graphical illustration of such setting is in Figure 3 (b).
use thicker edges to denote stronger weights (which suggests shorter intervals). We tested the different strategies introduced in Section 3 to learn the temporal phenotypes. The composition coefficients for every patient will be used as their vector representations for the prediction tasks. For comparison purpose, we also implemented the following baselines:

- **Aggregated Vector Representation (AV).** This method represents every patient as a vector with dimensionality equal to the number of distinct medical events in all patients’ EHR records. The value on a specific dimension is just the frequency of the corresponding event in his/her EHR sequence.

- **Bag-of-Pattern Representation (BP).** This method first run a standard sequential pattern mining algorithm to detect frequent patterns from the patients’ EHR sequences, and those patterns will be combined together to form a pattern repository. Every patient will be represented as a vector with dimensionality equal to the size of such pattern repository. The value on a specific dimension will be the frequency that pattern appeared in the EHR sequence of the corresponding patient.

- **Event Signature Representation (ES).** This method implements the temporal signature mining algorithm proposed in [22], which identifies the temporal patterns in patient EHRs via a constrained optimization procedure. The patients will still be represented by the bag-of-pattern representation as in the BPS method.

After the vector based representation for every patient is derived, we then adopt Support Vector Machine (SVM) to perform prediction. The classification performance is measured by Area Under the Receiver Operating Characteristics Curve (AUC), Area Under the Precision Recall Curve (AUPR), and Accuracy (ACC), and these measures are averaged over 10-fold cross validation. The parameters in our methods are tuned with a greedy grid search strategy as follows.

We first construct the temporal graphs using the unsupervised method, and the locality controlling factor $r$ is tuned with cross validation on the prediction results using the signatures detected from the constructed graph. Then the number of bases is tuned based on the prediction results with unsupervised signature identification. Finally the tradeoff parameter for regularized signature identification methods is tuned with $r$ and number of signatures fixed. In both studies, we set $\Delta = 90$ days, as both are chronic disease scenarios.

| Table 1 summaries the quantitative results with parameters chosen in the ways described above. From the table we can observe that: (1) Prediction using the signatures mined from our proposed methods can achieve better prediction performance compared to those baselines, which suggests the effectiveness of the proposed graphical scheme; (2) Regularized signature identification can produce better results because they utilizes supervision information.

In addition to the quantitative results, it would also be interesting to examine the validity of the detected temporal signatures qualitatively. We present three signatures with largest magnitude of the average composition coefficients for each data set in Figure 5 and 6 respectively. For all three signatures in Figure 5 we can clearly observe the drug hubs...
Temporal Signature Identification

Despite the promising quantitative and qualitative results, there are several aspects of this framework that we want to specifically discuss here.

- Comparing to sequence based representation, graph based representation is more compact, but at the same time it will suffer from information loss. For example, if a pair of consecutive events with the same temporal ordering repeat multiple times within the EHR of a specific patient, they will only appear once in the constructed temporal graph and the weight of the edge linking them will be aggregated from all the durations between their appearances. Usually the trends of the variations of such durations between repeated pairwise events can be indicative of the progression of some impending disease conditions. Therefore a smart way of encoding such
information to the constructed temporal graph would be a great enhancement to the current representation.

- The graph construction process would be computationally expensive if the number of distinct events is large, and the following basis learning process will be time consuming as well because it is correlated with the dimensionality of the graph adjacency matrix, which is the number of the distinct events. One potential strategy that could make this process more efficient is the multilevel/hierarchical graph learning approach [23], where we can construct a hierarchy of graphs from coarse to fine by utilizing the event ontology. The patterns can be detected from the coarsened graph efficiently and refined to more detailed levels.

- As can be seen from Figure 5 and 6, the detected temporal signatures could be messy because of the high variability of the patient EHRs. Besides the multilevel strategy, it would also be interesting to investigate sparsity induced regularizers, which can make the learned signatures more interpretable and clear.

6 Conclusion

In this paper, we proposed a novel graph based representation for patient EHRs, which encodes distinct medical events as well as their temporal relationships. Compared to traditional sequence and matrix based representations, graphs are more compact and intuitive. We presented several approaches to identify interesting temporal phenotypes based on such graph based representation, and validated their effectiveness on real-world data sets.

DenguePredict: An Integrated Drug Repositioning Approach towards Drug Discovery for Dengue

QuanQiu Wang¹, MS, Rong Xu², PhD,

Abstract

Dengue is a viral disease of expanding global incidence without cures. Here we present a drug repositioning system (DenguePredict) leveraging upon a unique drug treatment database and vast amounts of disease- and drug-related data. We first constructed a large-scale genetic disease network with enriched dengue genetics data curated from biomedical literature. We applied a network-based ranking algorithm to find dengue-related diseases from the disease network. We then developed a novel algorithm to prioritize FDA-approved drugs from dengue-related diseases to treat dengue. When tested in a de-novo validation setting, DenguePredict found the only two drugs tested in clinical trials for treating dengue and ranked them highly: chloroquine ranked at top 0.96% and ivermectin at top 22.75%. We showed that drugs targeting immune systems and arachidonic acid metabolism-related apoptotic pathways might represent innovative drugs to treat dengue. In summary, DenguePredict, by combining comprehensive disease- and drug-related data and novel algorithms, may greatly facilitate drug discovery for dengue.

Introduction

Dengue is the most common vector-born viral infection in humans and the most rapidly spreading viral disease globally. Over 40% of the world’s population live in dengue-endemic areas, and about 50 to 100 million people are infected with the dengue virus every year. Currently, there are no curative drugs for dengue [1-3]. Therefore, cost-effective approaches are needed to rapidly discover innovative drug treatments for it. Drug repositioning is a drug discovery strategy that seeks to renew failed drugs or expand indications for approved drugs [4]. Currently, computational drug repositioning has not yet been applied to the search for drug treatments for dengue [5].

Disease genetics provide strong evidence to connect genes to human diseases. Variations in several genes have been shown to influence susceptibility and resistance to the dengue virus, as well as disease progression and severity [6-9]. These genes are involved in multiple genetic pathways associated with dengue as well as many other diseases. We hypothesize that diseases that share high genetic relevance with dengue may offer insights into disease biological basis and provide unique opportunities in developing effective drug treatments for dengue. Here we present a drug repositioning system (DenguePredict) that first finds diseases that are genetically related to dengue and then use dengue-related diseases as a window into understanding the biology of dengue and discovering drug candidates to treat it. Our study is different from current disease genetics-based drug discovery studies, which often directly infer drug targets from disease-associated genes [10-11]. To directly translate disease genetics into therapeutics, we need to know that disease-associated genes are involved in disease pathogenesis. However, the genetic basis of many diseases, including dengue, still remains unknown and the effect size of many disease-associated genes, for instance disease-associated genes discovered through genome-wide association studies (GWAS), is generally modest. Here we present an alternative strategy to circumvent these obstacles. We use disease genetics data as merely a starting point to infer interconnections among thousands of diseases and then develop a novel drug repositioning strategy to infer drug treatments based on these genetically related diseases and their associated drug treatments. Our intuition is that if two diseases share high genetic relevance, it is likely that these two diseases are related in pathophysiology even though the exact biology may remain unknown, therefore drugs that are effective in treating one disease may treat the other.

DenguePredict is a computation-based drug repositioning system. Computational drug repositioning approaches can be classified as drug-based, disease-based, and both [12-14]. Drug-based approaches leverage upon known drug molecular structures or functions such as chemical structure and properties, molecular docking, gene expression and drug side effects [15-21]. It was recognized that drug screens based on existing drugs might fail to identify new therapeutic mechanisms [22]. On the other hand, disease-based approaches put less emphasis on existing drugs and focus more on disease mechanisms and interrelationships, therefore have potential in discovering truly innovative
drugs. Disease-based approaches used disease-related data ranging from genome [10-11, 19-20] to phenome [23-27]. Many drug repositioning systems used well-established computational and statistical algorithms, including regression/classification, machine learning, network analysis, and text mining [14]. The keys to the success of a computational drug repositioning system include both the unique datasets included in the system as well as innovative ways in integrating various disease- and drug-related data towards specific problems (i.e. specific diseases or drugs).

There are three key components in DenguePredict. First DenguePredict contains a comprehensive drug-disease treatment relationship knowledge base (TreatKB) that we recently constructed from multiple heterogeneous and complementary data resources using advanced computational techniques including natural language processing, text mining and data mining [28-30]. TreatKB includes 9,216 drug-disease treatment pairs extracted from FDA drug labels, 111,862 pairs extracted from the FDA Adverse Event Reporting System (FAERS), a database supporting the FDA’s post-marketing drug safety surveillance, 34,306 pairs extracted from 22 million published biomedical literature abstracts, and 69,724 pairs extracted from 171,805 clinical trials. All together, TreatKB contains 208,330 drug-disease treatment pairs for 2484 drugs and 24,511 diseases. Second, we used disease genetics data from both the Online Mendelian Inheritance in Man (OMIM), a comprehensive database of human genes and genetic phenotypes [31], and the Catalog of Published Genome-Wide Association Studies from the US National Human Genome Research Institute (NHGRI), an exhaustive source containing the description of disease-trait-associated single nucleotide polymorphisms (SNPs) from published GWAS data [32]. We then enriched these disease genetics data by manually curating dengue-associated genes from published biomedical literature. Third, we used a novel signal prioritization algorithm that we recently developed [25] to find candidate drugs from dengue-related diseases.

Materials and methods

DenguePredict is depicted in Fig. 1 and consists of the following steps: (1) we constructed an integrated genetic disease network (GDN) using disease-gene associations and protein-protein interaction data from multiple large data resources. We applied a network-based ranking algorithm to find dengue-related diseases from GDN; (2) we examined what kinds of diseases and genetic pathways were enriched among top-ranked diseases; (3) we developed a drug repositioning approach to systematically transfer drugs from dengue-related diseases to treat dengue itself. We evaluated DenguePredict using the only two drugs that have been tested in clinical trials for the treatment of dengue; and (4) in order to better understand the top-ranked repositioned drug candidates, we determined which classes of drugs were enriched and which common genetic pathways these drug candidates target.

Fig.1. The drug repositioning and analysis pipeline of DenguePredict.

1. Construct an integrated genetic disease network (GDN) and find dengue-related diseases from GDN

1.1 Construct GDNs

We used disease-gene association data from three data resources to construct GDN. The first resource is the OMIM database [31]. We downloaded the OMIM database and mapped gene names to their corresponding approved human gene symbols as defined by the HUGO Gene Nomenclature Committee (HGNC) [33]. We extracted a total of 15,462 disease-gene pairs, representing 5,983 diseases and 8,831 genes.
The second source is the GWAS Catalog [32]. We mapped SNPs to their associated strongest genes, which were subsequently mapped to their corresponding approved human gene symbols as defined by the HGNC. In total, we obtained 22,470 disease/traits-gene pairs, representing 881 diseases/traits and 8,689 genes.

The third source is the published biomedical literature. We manually curated dengue-related biomedical literature and enriched dengue-associated genes included in OMIM and the GWAS Catalog. We classified curated dengue-gene pairs into genetics-based (to enrich data in OMIM) and genomics-based (to enrich data in the GWAS Catalog). Due to the intensive manual effort, we only curated dengue-associated genes from literature.

We first built two sub-networks separately using disease-gene associations from OMIM (GDN_OMIM) and the GWAS catalog (GDN_GWAS). We then integrated them into one network. On both sub-networks, two diseases were connected if their associated genes (proteins) interacted. The edge weights were determined by the numbers of protein-protein interaction (PPI) pairs between two diseases. The PPI data was obtained from the STRING database [34]. From the STRING database, we obtained a total of 4,137,054 human PPI pairs representing 17,756 human proteins. In building the integrated GDN, we mapped nodes in GDN_OMIM to the nodes in GDN_GWAS if the nodes represented the same diseases. The mapping was done based through the unified medical language system (UMLS) Concept Unique IDs (CUIs) [35]. The fact that only 29 diseases mapped between OMIM and GWAS Catalog demonstrate that the diseases in these two databases are largely complementary and that our mapping algorithm needs further improvements. For comparison, we also generated ten random networks by randomly shuffling the edges of the real GDN while maintaining the proportion of edges between diseases. The summary statistics of GDN and the two sub-networks are shown in Table 1.

1.2 Find diseases that share high genetics with dengue from GDN

Recently we develop network-based ranking algorithms to prioritize genes for a given disease [27, 36], to prioritize diseases for a given disease [25], and to prioritize diseases for a given microbial metabolite [37]. In this study, we applied these network-based ranking algorithms to find diseases that share high genetics with dengue. The iterative ranking algorithm is defined as: $p^{t+1} = (1-r)Wp^t + rp^0$, wherein $W$ is the column-normalized adjacency matrix of the integrated GDN (the equal transition probability between GDN_OMIM and GDN_GWAS) and $p^0$ is a vector in which the $i$-th element held the normalized ranking score of disease $i$ at $t$-th iteration. The initial probability vector $p^0$ contains dengue with a probability of 1.0. Other diseases are then ranked according to the steady-state probability vector, which is obtained by iterating the algorithm until the change between $p^{t+1}$ and $p^t$ is less than $10^{-6}$.

2 Analyze top-ranked diseases that share a high degree of genetic similarity with dengue

2.1 Analyze disease classes among ranked dengue-related diseases

To systematically understand dengue-related diseases, we examined disease classes enriched among top-ranked diseases retrieved from GDN with dengue as the input. We classified these diseases into sixteen categories using the 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD10) [38]. The ICD10 includes 22 highest-level disease classes. We used 16 of the 22 chapters and excluded six non-specific disease classes such as “Codes for special purposes,” and “Injury, poisoning and certain other consequences of external causes.” Since the terms used in ICD10 are often different from those in GDN, we mapped disease terms in ICD10 to their synonyms through UMLS CUIs [35]. We retrieved a list of ranked dengue-related diseases from GDN. For diseases at 10 different ranking cutoffs (top 10%, 20%, ... 100%), we calculated percentages of the sixteen disease classes among them.

2.2 Analyze genetic pathways shared among ranked dengue-related diseases

To gain insights into common mechanistic relationships shared among dengue-related diseases, we analyzed genetic pathways associated with them. Functions of highly enriched pathways might provide insights into common molecular mechanisms shared among dengue-related diseases. First, we retrieved disease-associated genes from OMIM and from the GWAS catalog. We ranked each gene based on how many of the dengue-related diseases it was
associated with as well as the ranking scores of those diseases: 
\[ R_{\text{gene}} = \sum_{i=1}^{n} R_{\text{disease},i} \],
where \( n \) is the number of dengue-related diseases that the gene is associated with and \( R_{\text{disease},i} \) is the disease ranking score (as determined by the network-based disease ranking algorithm described above). We then analyzed gene-associated pathways using pathway data from the Molecular Signatures Database (MSigDB), a collection of 10,295 annotated genetic pathways or gene sets from multiple sources [39]. We ranked these pathways based on the number of genes associated with dengue-related diseases as well as the rank scores of those genes: 
\[ R_{\text{pathway}} = \sum_{i=1}^{n} R_{\text{gene},i} \],
where \( n \) is the number of genes that the pathway contains and \( R_{\text{gene},i} \) is the gene ranking score as determined above. We compared top-ranked pathways for GDN to those for random GDNs in order to identify pathways enriched for dengue-related diseases.

3 Reposition drugs associated with dengue-related diseases to treat dengue

3.1 Drug repositioning algorithm
We ranked FDA-approved drugs by the number of dengue-related diseases that they could treat as well as the ranking scores of those diseases. The drug prioritization algorithm is defined as: 
\[ R_{\text{drug}} = \sum_{i=1}^{n} R_{\text{disease},i} \],
wherein \( n \) is the number of dengue-related diseases that can be treated by a drug and \( R_{\text{disease},i} \) is the disease ranking score (as determined by the network-based disease ranking algorithm described above).

3.2 De-novo validation using dengue drugs tested in clinical trials
The inputs to the drug prioritization algorithm are a ranked list of dengue-related diseases (output from the disease ranking algorithm) and their associated drug treatments as determined by the drug-disease treatment pairs from four TreatKBs. Since the inputs contain neither dengue nor dengue-related treatment information, thereby our evaluation is in fact a de novo validation approach. Since no FDA-approved drugs are currently available for the treatment of dengue, we used drugs that have been tested in clinical trials for evaluation. We retrieved a total of 101 dengue-related clinical trials from ClinicalTrials.gov (www.clinicaltrials.gov). While most of these trials test vaccines, five trials tested five different drugs: chloroquine (NCT00849602), ivermectin (NCT020445069), balapiravir (NCT01096576), celgosivir (NCT01619969), and uv-4B (NCT020661358). Among these five drugs, only chloroquine and ivermectin are FDA-approved drugs: chloroquine approved for treating malaria and amebiasis, and ivermectin approved for treating onchocerciasis and strongyloidiasis. For our drug repositioning purpose, we used the two FDA-approved drugs (chloroquine and ivermectin) as the gold standard. We calculated the rankings of these two drugs among all FDA-approved drugs. The higher these two gold standard drugs were ranked, the better the ranking algorithm was. We compared the rankings of these two drugs derived from GDN to those from ten randomly generated GDNs. In addition, we also compared the performances across the four different TreatKBs.

4 Analyze top-ranked drug candidates

4.1 Analyze drug classes among ranked drug candidates
We examined which classes of drugs were enriched among top-ranked repositioned drug candidates. We classified drugs using drug classes defined by the Anatomical Therapeutic Chemical (ATC) classification system [40]. The ATC system consists of 13 first-level codes, which were further classified into 94 second-level codes, 267 third-level codes, 882 fourth-level codes, and 4,580 fifth-level codes, which are individual drugs. We experimented classifying drugs using different level ATC codes and found that the third level ATC codes provided sufficient but not too fine-grained granularity.

4.2 Analyze genetic pathways targeted by repositioned drug candidates
To understand the common mechanisms of action underlying top-ranked repositioned drug candidates, we analyzed genetic pathways targeted by these drug candidates. The method for drug pathway analysis was similar to that used for disease pathway analysis as described above, except that the drug-target gene association data was from DrugBank [41]. We compared top-ranked pathways based on GDN to those based on random GDNs in order to identify pathways enriched for repositioned dengue drug candidates. Functions of these enriched pathways might provide insights into common molecular mechanisms targeted by drug candidates. We performed literature search for supporting evidence that these enriched pathways might be targeted for dengue treatments.
Results

1. Infectious and parasitic diseases, neoplasms, and diseases of the digestive system are enriched among top-ranked dengue-related diseases

Using dengue as the input, we retrieved a ranked list of 4729 diseases from GDN. The disease class “Certain infectious and parasitic diseases” was highly enriched among top-ranked diseases: 9.73% among top 10% ranked diseases as compare to 1.46% among all diseases. This is expected, since dengue is known to share genetics with other infectious diseases such as malaria, Mycobacterium tuberculosis, and HIV [42-44]. Therefore, the enrichment of this disease class among diseases retrieved from GDN roughly served as a positive control in validating both network construction and disease ranking algorithms. Interestingly, two other disease classes “Neoplasms” and “Diseases of the digestive system” were also significantly enriched among top-ranked diseases. For comparison, none of the sixteen disease classes were enriched when the randomly generated GDNs were used (data not shown).

Fig. 2. Three ICD10AM disease classes were enriched among top-ranked diseases retrieved from GDN.

2. Immune-related pathways may be the common mechanisms underlying dengue and its related diseases

Fig. 3 shows the top fifteen enriched pathways and their percentages among all retrieved pathways. Among these enriched pathways, at least nine pathways are involved in human immune system, including “REACTOME IMMUNE SYSTEM,” “KEGG FC EPSILON RI SIGNALING PATHWAY,” and “REACTOME ADAPTIVE IMMUNE SYSTEM.” Experimental and observational findings in past years suggest that immune system-related mechanisms are involved in dengue pathophysiology. Dengue fever is characterized by thrombocytopenia and vascular leak with altered plasma cytokine profiles. Suggested immune mechanisms include platelet activation and apoptosis modulating monocyte inflammatory responses, increased levels of mediators like tumor necrosis factor-α and interleukin-1β [45], interplay between plasmablasts, platelets, and complements [45], disruption of the interaction of Daxx and NF-kB to induce CD137-mediated apoptosis [47], immunodominance changes [48], the involvement of Notch signaling pathways to modulate host adaptive immune response and altered profiles of cytokines produced by cross-reactive T cells [49].
Four cancer-related pathways were also enriched, including “KEGG PATHWAYS IN CANCER,” “KEGG ENDOMETRIAL CANCER,” “KEGG PROSTATE CANCER,” and “KEGG COLORECTAL CANCER.” The same enrichment for cancers was observed in above disease class enrichment analysis. However, we could not find literature evidence supporting the direct relationship between dengue and cancers. Since immunopathogeneseis are known to be involved in many cancers and dengue, common immune mechanisms may underlie both dengue and cancers. Studies have shown that carica papaya leaves exhibits both anti-tumor activity and immunomodulatory effects in dengue [50-51]. In summary, by systematically analyzing genetic pathways involved with dengue-related diseases, we can gain deeper insights into molecular mechanisms underlying dengue and its related diseases.

3. DenguePredict found the two clinical trial dengue drugs and ranked them highly
As shown in Table 2, DenguePredict consistently ranked chloroquine highly (ranging from top 0.96% to 5.98%). Ivermectin was ranked lower than chloroquine, but still significantly higher than those derived with random GDNs. Comparing across four TreatKBs, DenguePredict using the MEDLINE-based TreatKB performed the best, with chloroquine ranked at 0.96% and ivermectine at 22.75%. Combining drug-disease treatment pairs from all four databases did not improve the performance (data not shown). The fact that we ranked both chloroquine and ivermectin highly demonstrated the validity of our repositioning strategy. The output of DenguePredict is a list of FDA-approved drugs ranked based on their likelihood for treating dengue.

Table 3. Top 10 drug candidates repositioned from four TreatKBs.

We examined which classes of drugs were enriched and analyzed genetic pathways associated with highly-ranked drug candidates. As shown in Fig. 4, the most enriched (more than 25-fold enrichment as compared to random GDNs) drug class was “Other analgesics and antipyretics.” This finding is consistent with the current symptomatic and supportive treatment for dengue using analgesic-antipyretic therapy for the relief of lethargy, malaise, and fever associated with the disease [2]. The second most enriched drug class was “anti-inflammatory and anti-rheumatic products” (15-fold enrichment), which includes corticosteroids. Corticosteroids are potent anti-inflammatory agents with a wide range of effects on the immune system. Observational studies have suggested that corticosteroids may benefit people with dengue-related shock and may prevent disease progression [52]. Our study provides independent mechanistic evidence supporting treatment benefits of corticosteroids in the treatment of dengue.
5. Repositioned drug candidates mainly target apoptosis- and immune-related pathways

Fig. 5 shows top 21 enriched pathways for repositioned drug candidates. The pathway involved in arachidonic acid metabolism showed 28-fold enrichment as compared to random networks. Arachidonic acid (AA) is a lipid second messenger generated by hydrolysis of membrane phospholipids via phospholipase A2 (PLA2). Malewicz et al. reported that dengue virus was able to activate PLA2 and generate AA [53]. Jan et al. showed that AA, superoxide anion, and NF-kappa B are sequentially involved in dengue virus-triggered apoptotic pathways in human neuroblastoma cells and that inhibition of PLA(2) activity by the PLA(2) inhibitors diminished DEN-2 virus-induced apoptosis [54]. Many of these top enriched pathways are related to immune systems, including natural killer cell mediated cytotoxicity, complement pathway, immunoregulatory interactions, and B lymphocyte pathways. This is consistent with the pathway analysis for dengue-related diseases. In summary, our study indicates that repositioned drug candidates that target arachidonic acid metabolism and/or immune systems might benefit people with dengue. While we did not perform literature search for all other enriched pathways, further investigating these pathways may generate novel hypotheses for dengue drug discovery.
Discussion
By leveraging upon vast amount of knowledge of disease genetics, drug targets, protein interactions, and drug treatments, DenguePredict effectively ranked the only two drugs currently under clinical trial for the treatment of dengue highly. Our approach also suggested potential genetic pathways involved in disease mechanisms and mechanisms of actions of the drug repositioning candidates, which warrants further investigation. DenguePredict is highly generalizable and can easily be retargeted to find drug candidates for other genetic diseases. We expect that its performance will vary among specific diseases and critically depends on the data (both available disease genetics and drug treatments) included for each disease.

We were unable to compare DenguePredict to existing computational drug repositioning systems since these systems did not include dengue in their study. For example, in a recent study, Gottlieb et al used disease-disease similarities and drug-drug similarities from multiple databases to construct a classifier (PREDICT) to determine treatment associations between 593 drugs and 313 diseases [24]. While PREDICT is among currently most comprehensive drug repositioning systems, dengue was not included. On the other hand, DenguePredict included significantly more drugs and diseases: 5,675 diseases on GDN; 2,484 drugs and 24,511 diseases in TreatKBs.

Our study can be further improved in several aspects. First, we can further reprioritize the generated ranked list of repurposed drug candidates by their costs. Dengue is most prevalent in developing countries; therefore costs of drugs needs to be considered. Second, our study generated lists of putative genetic pathways that might be involved with dengue-related diseases and drug candidates, however these candidates will evolve as new disease-associated genes are discovered. For example, as new genes are discovered for dengue or other diseases, more diseases will be linked to dengue from the updated genetic network. Third, we validated our repositioning algorithm using the two clinical trial dengue drugs. Due to the small size of our testing data, we are still uncertain about the precision of top-ranked drug candidates. Experimental or clinical studies are needed to test those candidates.

Mortality Prediction in ICUs Using
A Novel Time-Slicing Cox Regression Method

Abstract
Over the last few decades, machine learning and data mining have been increasingly used for clinical prediction in ICUs. However, there is still a huge gap in making full use of the time-series data generated from ICUs. Aiming at filling this gap, we propose a novel approach entitled Time Slicing Cox regression (TS-Cox), which extends the classical Cox regression into a classification method on multi-dimensional time-series. Unlike traditional classifiers such as logistic regression and support vector machines, our model not only incorporates the discriminative features derived from the time-series, but also naturally exploits the temporal orders of these features based on a Cox-like function. Empirical evaluation on MIMIC-II database demonstrates the efficacy of the TS-Cox model. Our TS-Cox model outperforms all other baseline models by a good margin in terms of AUC.PR, sensitivity and PPV, which indicates that TS-Cox may be a promising tool for mortality prediction in ICUs.

Introduction
Over the last few decades, machine learning and data mining techniques are increasingly used for ICU mortality prediction. For example, PhysioNet/CinC organized a challenge in 2012 to develop methods for patient-specific prediction of in-hospital mortality [1], where the data includes time series of vital signs during the 48 hours after ICU admission. There are two tracks in this competition concerning binary outcome measurement (dead or alive) evaluated by sensitivity and positive predictive value (PPV), and risk estimation evaluated by a range-normalized Hosmer-Lemeshow statistic. A great deal of models submitted by participants largely outperformed the baseline algorithm (SAPS-1). For example, Johnson et al [2] used a novel Bayesian ensemble learning algorithm, and Krajnak et al [3] combined machine learning and clinical rules to build a predictive model. Existing algorithms do not fully take advantage of the temporal changes of the input clinical time-series data. Models such as logistic regression (LR), support vector machine (SVM), and decision trees (DT) can only handle static and fixed-length feature vectors, which greatly limit their use on time-series. In this regard, it makes more sense to resort to Cox regression since it takes into account the temporal orderings of various features and it has widespread uses in survival analysis. In the following, we mainly survey the literature related to Cox regression in the area of medical care utilization.

Cox regression [4,5], though invented in the seventies, is still receiving significant interests from the domains of both healthcare and information technology. Different from methods mentioned above, Cox regression is one of the few models that take into account the temporal structure of events, which is very important for using time-series data to predict morbidity, readmission and mortality and to identify the associated factors. One of the classical examples for predicting morbidity is the risk assessment of cardiovascular disease [4]. A few studies also applied the Cox model for the prediction of outcome in patients with diabetes [6,7], stroke prediction [8], as well as ecologic studies [9]. These algorithms use the vast domain-specific knowledge that has been accumulated on the disease to manually select a limited number of risk factors and then put them into a Cox model.

Recent studies have also recommended using various machine-learning techniques combined with Cox regression for diverse topics in healthcare [10,11]. In addition, there have been a great effort towards making Cox regression more generalizable by adding regularizations to the parameters [12-15]. The above methods typically work on relational data with factors such as age, gender, race, weight, ecologic exposures, lab variables and clinical risk factors. Although some factors may be time-varying, they are typically processed in the canonical way. However, few have used Cox regression to classify multi-dimensional time-series
data, due to the challenge that Cox regression is originally proposed for survival analysis and cannot be directly used in time-series classification.

To address this problem, we propose in this paper a novel approach named Time Slicing Cox regression (TS-Cox), which not only takes advantage of Cox regression, but also can be applied on clinical time-series data. Specifically, the rich time-series data allow us to used sophisticated features such as statistical moments, powers in frequency domain, estimates in chaos theory and entropies in information theory as a novel set of covariates to predict mortality risk. Then, based on time-to-event characteristics of ICU data, we divide each time series into multiple windows for each waveform and extract features from every sliding window via signal analysis. Next, we employ Cox regression on those windows together with their associated time stamp information. After the model is trained, we are able to compute a hazard ratio as risk score for each waveform based on the extracted features and learnt model. Our TS-Cox model allows us to leverage on both powerful time-series features and the survival information in the time domain. To our knowledge, this is the first work that adapts Cox regression to classify multi-dimensional time-series.

The remainder of this paper is organized as follows. First, we introduce some background on the original Cox model and describe the proposed TS-Cox model. Next, empirical results of our TS-Cox model compared with baseline methods are presented and discussed. Finally, we summarize the research work and draw conclusions.

**Methods**

**Feature extraction method**

The input of our model is based on the features extracted from the multiple time-series of each patient. Many of our features are inspired by classic signal analysis methods including RR series distribution patterns (Mean, Median, Variance, Skewness, Kurtosis), magnitude of variability in the time domain (SD, RMSSD), and linear estimates in the frequency domain (power of VLF, LF, HF and LF/HF). A complete recipe for extracting these physiological features can be found in [16].

Besides, we also make use of features kindled by chaos theory and information theory, which are helpful in analyzing the degree of self-affinity and randomness of the time-series. Specifically, we adopt the detrended fluctuation analysis (DFA) based on chaos theory to estimate the statistical self-similarity of a signal [17-19]. We also compute the randomness measurements including approximate entropy [20,21], sample entropy [22,23] and permutation entropy [24]. They are measurements designed to quantify the degree of regularity versus unpredictability, reflecting the unpredictability of fluctuation in a time-series. A low value of the entropy indicates that the time-series is deterministic while a high value means that the time-series is unpredictable. These entropies are good indicators for cardiovascular signals where the occurrence of disease is highly correlated with the decrease of entropy. In summary, in this study we extracted 16 features from two types of time-series: heart rate (HR) and peripheral capillary oxygen saturation (SpO2), leading to 32 features in total for each time window of a patient.

**Classification method**

**Cox Regression**

Cox regression is a popular statistical model in survival analysis which deals with analysis of time duration until the happening of one or more events, such as sudden deterioration of a patient [4]. It estimates the risk of the occurrence of a particular event at a particular time stamp by quantifying the relation between the features and the risks.

Now we describe the Cox regression model. Let $X=(x_1, x_2, ..., x_m)$ be the feature vector for each patient where $m$ is the number of features. In this paper, the features come from the aforementioned signal analysis method. Let $h(t)$ be a hazard function assessing the instantaneous risk of an event (e.g. mortality) at time $t$. The Cox regression expresses the logarithm of the mortality risk $h(t)$ as a weighted sum of all features with a base function as follows:

$$\log h(t \mid X) = \alpha(t) + \beta_1 x_1 + \beta_2 x_2 + ... + \beta_m x_m,$$

where $\beta_i$ is the coefficient of feature $x_i$, reflecting the relation between this feature and the risk. For example, a large $\beta_i$ means that the raise of the value of feature $x_i$ increases the risk of mortality. $\alpha(t)$ is a base function independent
from the feature vector $X$ whose output varies over time depending on $t$. Given the above equation (1), we have that

$$ h(t \mid X) = \frac{h_0(t)}{\prod_{i=1}^{m} \exp(\beta_i X_i)} $$

where $h_0(t)$ is called baseline hazard function and the following product is called proportional hazards. The proportional hazards assume that each feature contributes an independent multiplicative factor to the primary risk hazard rate. Cox regression estimates the parameters $\beta$ using maximum likelihood estimation over the partial log-likelihood function in which $h_0(t)$ is cancelled out. Consequently, we do not need to know the functional form of $h_0(t)$ as the output does not depend on the feature vector. Given a fixed time stamp $t$, the risk hazard rate $h(t, X)$ only depends on the feature values. Therefore, when computing the risk hazard rate at a particular time stamp in the future, we only need to compute the proportional hazards as a proxy for risk hazard rate.

The problem of survival analysis is further compounded by the presence of censored data [25,26], where the status of an instance is not observable after a certain time point. For example, an instance in mortality analysis is censored when the patient at question is still alive at the end of observation. Censored times $C_i$ are associated with each instance $i$ along with observed time for the event $O_i$. Define the failure time $T_i$ for instance $i$ as the minimum of $O_i$ and $C_i$, i.e., $T_i = \min(O_i, C_i)$. $O_i \leq C_i$ indicates that the event of interest has occurred within the censoring time. However, if $O_i$ is unknown then $T_i$ is set to $C_i$ and the instance is censored. Take hospital readmission prediction as an example. An event is defined as the onset of heart failure readmission within 30 days of discharge from the previous admission. The censored cases can be identified when (i) the patients whose follow-up details were lost over time or (ii) the patients was not readmitted within the time period of follow-up until the end of the study (which is fixed to 30 days in this case). This is commonly called the right censoring setting, which is the most frequently studied censoring phenomena in survival analysis.

**Time Slicing Cox regression (TS-Cox)**

Now we introduce our Time Slicing Cox regression (TS-Cox) method, which applies the Cox model to time-series data. Our method contains three steps: preprocessing, training, and deployment. We describe these three steps in detail as follows.

**Preprocessing.** We assume that the time-series has a basic unit step which is the time gap between two measurements. For example, in our data from MIMIC-II, each unit step is 60 seconds. For each patient, we maintain a sliding window from the beginning of each of his or her time-series. The window is a fixed-length time frame (e.g., window size =1024 unit steps) that can be regarded as a snapshot of the status of a patient. At each iteration, we extract features from the time window and record the time stamp of this window. We then move the window by a fixed step-size and repeat until we reach the end of the patient’s time-series.

For each time window, we adopt the aforementioned feature extraction method to obtain features from the time-series within the window. In our case, each time window is associated with two time-series for HR and SpO2. We extract 16 features from each time-series separately, leading to 32 features in total for each time window.

In each iteration, we move the window by a pre-specified step size (e.g., 100 unit steps) and extract features again for the new window. This way, we have multiple windows for each patient. Suppose the number of windows for a patient is $L$. Each window is also associated with a new failure time, which is the time gap between the end of the window and the original failure time $T$. Let $D_l$ be the last time stamp of window $l$, $l = 1, ..., L$, and $S_l$ be the failure time for window $l$, we have that $S_l = \max(T - D_l, 0)$. At the end of preprocessing, for each patient we have $L$ windows where each window $l$ is associated with 32 features and a failure time $S_l$ reflecting the new survival time for that window.

**Training.** The training procedure is to estimate the value of $\beta$, which largely follows the same workflow for Cox regression. Different from the original Cox regression where each training instance is a patient, our TS-Cox model counts each window of each patient as a training instance. In other words, each window is viewed as a unique patient. This way, the TS-Cox model considers the time-varying migration of features and the temporal ordering of all the time windows. In contrast, if we extract features directly from the entire time-series for all patients and then input them into models such as LR or SVM, we would lose such temporal information.
We still learn a weight vector $\beta$ using maximum likelihood estimation after training the TS-Cox model. For example, if there are 32 features for each time window, the length of the vector $\beta$ is 32. The training process is to tune the value of $\beta$ so that the resulting risk hazard rates for all training instances best respect the order of their failure time $S_t$.

**Deployment.** With the learnt $\beta$ in place after training, the evaluation procedure is to evaluate the risk of mortality for an out-of-sample patient. Specifically, given a patient, we extract the 32 features from their last time window using the same window size as in preprocessing and training. We then compute the proportional hazard $h'(X)$ which is the exponential of the dot product of $\beta$ and the feature vector $X$, i.e. $h'(X) = \exp(\beta X)$ as the hazard risk rate. To use the proportional hazard rate for binary classification, we need to set a threshold $c$ so that those patients with $h'(X)>c$ belong to one class and the rest belongs to another class. The threshold $c$ is typically chosen by aiming at a prescribed specificity, sensitivity, or positive predictive value (PPV) based on cross-validation on the training data.

In practice, our model can be deployed to monitor patients in real-time. We can move the time window to the last point as new data come in, extract updated features, and re-compute the hazard rate by feeding the updated features into the TS-Cox model. An alert will be triggered when the criterion (such as $h'(X)>c$) for certain event is met.

**Results and Discussion**

We conduct experiments to evaluate the performance of the proposed method. In our experiments, we used a publicly available ICU database, namely Multiparameter Intelligent Monitoring in Intensive Care II (MIMIC II) [27]. The data harnessed in MIMIC-II were collected from the ICUs of Beth Israel Deaconess Medical Center from 2001 to 2008 and covers 26,870 adult hospital admissions (version 2.6). Two types of data were obtained: clinical data and physiological waveforms. The clinical data were acquired from the CareVue Clinical Information System (models M2331A and M1215A; Philips Healthcare, Andover, MA) and the hospital’s electronic archives. The data included patient demographics, nursing notes, discharge summaries, continuous intravenous drip medications, laboratory test results, and nurse-verified hourly vital signs, etc. The physiological waveforms were collected from bedside monitors (Component Monitoring System Intellivue MP-70; Philips Healthcare) and included high-resolution (125 Hz) waveforms (e.g., electrocardiograms), derived time series such as HR, blood pressures, SpO2, and monitor-generated alarms [28]. Here, we only extracted the time series of HR and SpO2 as the inputs to our model. Finally, our experiment datasets consist of 930 waveforms including complete HR and SpO2 records, among which there are 56 dead and 874 censored records. Our task is to predict whether a patient will die in the ICU.

We compare our method with the following baselines: 1) Classical classifiers including logistic regression (LR), linear SVM (SVM-I) and SVM with RBF kernel (SVM-r). Specially, we follow the traditional approach of first extracting features from the whole time series and then apply those classifiers for binary classification. 2) Time-Slicing version of logistic regression (TS-LR), linear SVM (TS-SVM-I) and SVM with RBF kernel (TS-SVM-r). In particular, we follow the same time-slicing mechanism as in TS-Cox and train these models on all time windows to learn the weight of each feature. When making prediction, we apply these learned weights on the last window of each waveform. For all time-slicing algorithms, we use 1024 unit steps as window size and 100 unit steps as step size for moving windows based on the previous experiments.

The dataset is highly imbalanced with the majority of patients being non-dead. Therefore, accuracy performance does not make the most sense in this case since one can achieve a high accuracy by always predicting non-dead for every patient. As a result, for evaluating the performance, we fixed the specificity of each model to about 0.95 and compare the sensitivity and PPV of each model. What’s more, we also evaluate the area under the ROC curve (AUC_ROC) and area under the precision-recall curve (AUC_PR). All the results reported in Table 1 are based on 5-fold cross validation. That is to say, we divide the whole dataset into 5 subsets where each subset contains 186 waveforms. Each algorithm is evaluated on each subset with all other 4 subsets being the training dataset. The final result is the mean of all evaluated subsets.

Table 1 below shows the results of all algorithms with specificity being fixed to 0.95. We make the following observations:
First of all, the proposed Cox regression with time slicing is better than the original Cox regression regardless of any measurements, which demonstrates the efficacy of using time slicing techniques in the Cox regression model. The advantage of Cox regression is that it takes time-to-event into consideration, while other models do not. Therefore, time slicing techniques work for Cox regression, but do not help other models since it merely increases the training instances for these classifiers.

Second, TS-Cox has both the largest AUC_ROC and the largest AUC_PR. Furthermore, TS-Cox surpasses all other models by a larger margin in regard of AUC_PR than of AUC_ROC, which signify that it makes more sense to measure AUC_PR than to estimate AUC_ROC for a skewed class distribution (most people still alive).

Third, the TS-Cox model constantly outperforms all the baseline models in terms of sensitivity and PPV, which indicate that TS-Cox is superior to other prediction models. We attribute this promising progress to the fact that the TS-Cox model is able to exploit the rich time-variant information of clinical time-series data.

Therefore, TS-Cox has a potential advantage over other methods to predict mortality in adult ICU monitoring system.

Conclusions
This paper proposed an integrated architecture for predicting death events in adult ICU patients based on a combination of time-series feature extraction methods and a novel time-slicing Cox regression method. The former produces more discerning features, and the latter exploits the strategy of slicing time windows on the static Cox model according to its time-to-event characteristics. We compared our TS-Cox model to conventional Cox model as well as LR, SVM-l, SVM-r, and their time-slicing version. The experiments indicate that TS-Cox has the highest AUC_PR, sensitivity and PPV by a huge margin at a specificity value around 0.95. These promising results demonstrate the feasibility of our new framework for better mortality prediction in adult ICU monitoring system.

Abstract

Detection of early symptoms in cervical cancer is crucial for early treatment and survival. To find symptoms of cervical cancer in clinical text, Named Entity Recognition is needed. In this paper the Clinical Entity Finder, a machine-learning tool trained on annotated clinical text from a Swedish internal medicine emergency unit, is evaluated on cervical cancer records. The Clinical Entity Finder identifies entities of the types body part, finding and disorder and is extended with negation detection using the rule-based tool NegEx, to distinguish between negated and non-negated entities. To measure the performance of the tools on this new domain, two physicians annotated a set of clinical notes from the health records of cervical cancer patients. The inter-annotator agreement for finding, disorder and body part obtained an average F-score of 0.677 and the Clinical Entity Finder extended with NegEx had an average F-score of 0.667.

Introduction

Cervical cancer

Cervical cancer is one of the most common cancers worldwide¹, frequently affecting young women below age 40. Therefore screening and early detection is essential². While cervical cancer incidence and mortality rates have dropped in countries where screening procedures have evolved into established prevention methods³⁴, the rates in less developed countries are still high.

Cervical cancer, highly mortal in advanced stages, is usually described as having few early symptoms except vaginal discharge, bleeding and pain post coitus. Early detection of cervical cancer is however crucial for treating it successfully. Novel ways to diagnose the disorder at even earlier stages would be highly valuable, as this could prevent treatable pre-cancer from turning into invasive cancer⁴. Early detection is yet sometimes hindered since not all women participate in cervical screening programs.

Today, electronic health records that describe the whole healthcare period of a patient are available in many countries including Sweden. To define and detect these possible early symptoms in a patient's health record, text-mining tools capable of identifying symptoms discriminatory for cervical cancer, are needed.

The overall aim of this study is to evaluate the performance of two previously developed text mining tools on health records of patients with cervical cancer, with a further aim to detect and discover early symptoms in a patient's medical history.

Text mining in the cervical cancer domain

Previous research in the field of text mining and cervical cancer has mostly focused on oncologic documents and pathology reports. One study used text mining of pathology reports, with the aim to transfer unstructured pathology reports to a structured database⁵. A review article⁶ regarding different approaches for clinical text mining within the cancer domain describes only two studies focused on cervical cancer. Both studies concern methods used to retrieve scientific oncology documents relevant to clinical decisions within a particular domain of cervical cancer. None of
them are in the domain of clinical text mining of symptoms relating to cervical cancer. However, there are two articles on the subject of cervical cancer staging. In the first, the authors used 250 cervical patient records for their experiments. The cervical cancer tumors were assigned 15 parameters to classify the stage of the cancer and 0.73 accuracy was obtained using a neural network architecture. In the second article, 221 cervical patient cases were used as input to a staging system using soft computing/neural networks. The cases were classified in stages I-IV and a classification score of 0.79 was obtained on test data. The C4.5 machine-learning algorithm was also applied on the data set, obtaining a score of 0.80.

In another study on tumor staging, the authors trained Naïve Bayes, Bayesian Network, Support Vector Machines, and Random Forest algorithms on manually annotated pathology reports from one hospital and evaluated the portability on another hospital’s pathology reports. They noted a decline in performance with at least 25 percent. However, in a later study they improved their results considerably to only a few percent decline in cross-hospital evaluation, by using feature selections to tune the classifiers and simple rules to identify numeric values.

**Named entity recognition and negation detection**

The Clinical Entity Finder (CEF) is a tool for entity recognition based on the machine-learning algorithm CRF++ and trained on manually annotated clinical entities in Swedish texts from an internal medicine emergency unit. An earlier approach to detect findings and disorders in the cervical cancer domain using Clinical Entity Finder revealed that many of the entities found by the tool were negated. Negations are important in essentially all clinical text, as many diagnoses are made based at least in part on exclusion of certain symptoms or test results. Negation detection have for example been incorporated in adverse drug reaction detection text mining workflows and similarly in the search for diagnostic codes in free text in electronic medical records. The Clinical Entity Finder has no built-in negation detection and a possible tool for negation detection in clinical text is NegEx, a rule based tool. NegEx has previously been adapted to Swedish with a set of Swedish negation triggers.

As it has been shown that different clinical subspecialties use clinical language with different distinctive features, a decrease in the performance of a natural language processing (NLP) system developed in one clinical domain is expected when applied in another clinical domain. The specific aim of this study is to investigate the efficiency of existing tools for text mining of Swedish health records, i.e. for entity recognition and negation detection, respectively, on the subdomain of clinical notes relevant for text mining studies on cervical cancer.

The research questions are:
- How well will a machine learning based tool (Clinical Entity Finder) trained on clinical notes from an internal medicine emergency unit automatically annotate cervical cancer symptoms in physicians’ notes from departments of gynecology and oncology?
- How well can the Swedish NegEx differentiate between negated and non-negated symptoms of cervical cancer?

**Methods and Materials**

**Data**

The Stockholm EPR Corpus is a database containing large quantities of clinical text in Swedish; over 600,000 patient records encompassing over 500 health care units from the Karolinska University Hospital. For this study, all patient records from the departments of obstetrics/gynecology and oncology from the years 2009-2010 with a diagnosis code for malignant neoplasms in the cervix (ICD-10 codes C53.0, C53.1, C53.8 and C53.9), were extracted, resulting in 646 patient records. The extracted data, containing notes from nurses, physicians and other professionals, is called the Cervical Cancer Corpus. Figure 1 shows the age distribution of the patients in the Cervical Cancer Corpus. For this study the physicians’ notes, in total 17,263 notes and 776,719 tokens were used.

Annotation

Annotation is the process of marking relevant entities in a text. This is performed manually by domain experts, and the annotation can be used to train a machine learning tool for automatic entity recognition. Manually annotated text is also used for the evaluation of such tools.

In this study, the entity types finding, disorder and body part were annotated. Both findings and disorders can be relevant as symptoms or indications of cervical cancer. The entity type body part is also relevant since it can give the location of symptoms. A finding is an observation made at a certain point in time and it is not necessarily abnormal, it can be a symptom reported by the patient as well as a finding from a medical examination. Disorders are abnormal and can be present even when they are not observable. The annotation performed in this study follows a set of guidelines based on those used when developing the Clinical Entity Finder, with added instructions for annotating negations.

Pre-annotation with the Clinical Entity Finder and NegEx

Pre-annotation is when a tool is used to mark relevant entities in a text before the manual annotation. This pre-annotation can then be used as a timesaving support for the annotators when doing the manual annotation. All physicians’ notes from the Cervical Cancer Corpus were pre-annotated using the Clinical Entity Finder. The Clinical Entity Finder was used to pre-annotate instances of the named entities body part, finding and disorder. To distinguish between negated and non-negated entities, the Clinical Entity Finder was augmented with the tool NegEx, which was used to classify entities of the types finding and disorder in the corpus as negated or non-negated. NegEx uses lists of negation triggers and looks for the presence of those triggers in text surrounding the annotated instances. A trigger can be a word or a sequence of words indicating negation. An example of a sentence with a negation is Patienten har ej smärta (The patient has no pain), where the finding smärta (pain) is negated by the trigger ej. Body parts and words outside of annotations were not investigated for negation.

Manual annotation of the physicians’ notes

Two physicians annotated subsets of the physicians’ notes from the Cervical Cancer Corpus. One physician is experienced in the text mining domain and in annotation (Annotator A), and one physician is an expert in the area of cervical cancer (Annotator B). They received the pre-annotated data, agreed on the interpretation of guidelines, and revised the annotations performed by the Clinical Entity Finder, using the Brat annotation tool. To properly evaluate the tools at least 100 manually annotated notes were considered as necessary to ensure variation and coverage. Annotator A and Annotator B annotated 180 and 100 notes respectively. The annotators removed faulty annotations, changed the span or type of annotations when needed, added missing annotations and marked annotations when negated. Figure 2 shows an example of a text pre-annotated by the Clinical Entity Finder with corrections carried out by Annotator A.
Figure 2. Screenshot of one sentence processed by the Brat annotation tool showing the pre-annotation in green and the manual annotation in blue. (Key phrases are translated to English).

An overview of the annotation pipeline is shown in Figure 3. The 17,263 physicians notes were firstly pre-annotated using the Clinical Entity Finder. In the next step all disorders and findings found by the Clinical Entity Finder were investigated for possible negations using NegEx. Finally, 180 of these pre-annotated notes were randomly selected for manual annotation (subset A). Annotator A corrected all of them, and Annotator B corrected 100 of them (subset B). The annotator agreement was measured on subset B and the performance of the Clinical Entity Finder was measured on subset A.

Figure 3. Annotation pipeline, note that subset B is covered by subset A, both annotators annotated subset B but Annotator A annotated another 80 notes.

Evaluation metrics

The performance of the tools was measured using precision (P), recall (R) and F1-score\(^2\). A high precision indicates that found named entities are correctly classified; a high recall shows that a large portion of named entities in the text are found, and the F1-score is the harmonic mean of the two. To calculate the scores, the number of true positives (TP), true negatives (TN) and false negatives (FN) were counted. A true positive is achieved when a tool has correctly annotated a named entity, a false positive occurs when a tool has incorrectly annotated a named entity, and a false negative when a tool has failed to detect a named entity that is present in the text.

\[
\text{Precision} = \frac{TP}{TP+FP} \\
\text{Recall} = \frac{TP}{TP+FN} \\
F1 = \frac{2*P*R}{P+R}
\]

The inter-annotator agreement between Annotator A and Annotator B was measured using the F1-score. The inter-annotator agreement can be viewed as an indicator of how well two individuals agree on this task and this can be compared to how well a tool can be expected to perform that same task.

Results

Results of the manual annotation

The annotators A and B each annotated 100 physicians’ notes from medical records of cervical cancer patients. Table 1 shows the confusion matrix for the two annotators. The rows show the annotations performed by Annotator A and the columns show the annotations performed by Annotator B. The diagonal shows the numbers of true positives - instances of named entities where the annotators agree on the type and the span of the annotation. To get
a match, the two annotators must pick the same exact span of text. An example of when the annotators have marked different spans is when one annotator marked the span *squamous cell carcinoma in situ* as a disorder but the other only marked the word *squamous cell carcinoma* in the same note. Such scope errors fall into the *No exact match* category, together with the cases of annotations carried out by only one of the annotators, either because of disagreement or by mistake. The level of inter-annotator agreement between Annotator A and Annotator B for exact and also partial match where there is at least one overlapping token (word), is shown in Table 2.

**Results of the annotation performed by the Clinical Entity Finder and NegEx.**

All of the physicians’ notes in the Cervical Cancer Corpus were processed by the Clinical Entity Finder and NegEx, and when evaluating the tools, the annotations carried out by Annotator A were used as a Gold Standard, assuming that Annotator A had correctly classified all named entities in the text. Annotator A and the tools were in complete agreement for 54 percent of annotations and Table 3 shows the confusion matrix for Annotator A and the tools, while Table 4 gives the precision, recall and F1-score for each of the entity types. Table 4 also demonstrates the improved scores when allowing partial matches, where there is at least one overlapping token, excluding punctuation.

Since NegEx only looks for negations when a finding or disorder has been annotated the performance of NegEx is directly dependent on the performance of the Clinical Entity Finder. The scores given in Table 4 for negated finding and negated disorder are therefore not perfectly suitable for evaluation of how well NegEx performs in the domain of cervical cancer. An additional evaluation has therefore been performed where all findings and disorders annotated both by Annotator A and CEF were selected. By selecting the instances already agreed on, the performance of NegEx could be isolated. There were 500 such instances and of those 57 were marked as negated by both Annotator A and NegEx. Precision, recall and F1-score for the ability of NegEx to correctly determine negations was calculated to be 0.78, 0.75 and 0.76 respectively.

Results of porting the Clinical Entity Finder

Table 5 shows the performance of the Clinical Entity Finder and NegEx in our setting compared to the performance of the Clinical Entity Finder applied to the type of data used to train on; health records from emergency units.

Error analysis

A manual error analysis has been performed on 60 of the annotated notes produced by the Clinical Entity Finder and NegEx as compared to the annotations done by Annotator A. The automatic and manual annotation most often classified the annotated entities in the same way, a recurring mistake, however, was made when a compound word for a disorder contained words describing a body part. Such compound words were sometimes wrongly classified as a body part. An example of this is the word *skelettmetastaser* (skeletal metastases), which contains the Swedish word for skeleton. Another source of error is the word *cervixcancer* (cervical cancer), a compound word in Swedish, which in many instances in the records was written as two words, *cervix cancer*. The CEF sometimes interpreted this as two separate entities; the body part cervix and the disorder cancer.

A second step of analysis was performed by looking at instances only annotated by either the automatic or manual annotation. The analysis found 333 false negatives, meaning annotations marked by Annotator A but missed by the tools, and 71 false positives, meaning annotations only performed by the tools. Table 6 shows the different errors sorted by type.
Table 6. The number of false positives and false negatives found in error analysis.

<table>
<thead>
<tr>

</tr>
<tr>
<td>False Negatives</td>
<td>65</td>
<td>116</td>
<td>132</td>
<td>20</td>
<td>333</td>
</tr>
</tbody>
</table>

After excluding scope errors, about half of the cases of false negatives in all categories were caused by the Clinical Entity Finder failing to detect words and expressions associated with cervical cancer. For example in the category body part, the word cervix was missed several times. The false negatives for disorders directly related to cervical cancer included for example dysplasi (dysplasia) and cancer in situ. Several of the missed disorders were either misspellings or abbreviations, for example the abbreviation cervixca for cervixcancer (cervical cancer in Swedish) and skivepitelcancer a misspelling of skivepitolcancer (squamous cell carcinoma) were both missed by the tools.

The largest source of false positives for disorders and findings were expressions describing procedures or drugs, for example preventivmedel (contraception). For body parts, the false positives originate from expressions where a body part word was part of a non-body part expression. For example, the expression över huvud taget (at all) contains the Swedish word for head (huvud), which causes a faulty annotation.

The individual evaluation of NegEx on 500 instances of findings and disorders resulted in 16 false positives and 19 false negatives. The false positives were almost all due to instances of findings and disorders appearing close to unrelated negation triggers. The false negatives were mainly caused by negation expressions being used that were not included in the lists of negation triggers used by NegEx and there was also a few cases were the manual annotation had failed to discover a negation and borderline cases.

Named entities and negations detected in the physicians’ notes.

Among the 776,719 tokens in physicians’ notes the Clinical Entity Finder identified 58,366 disorders, findings and body parts. Of these, 43,334 were either classified as findings or disorders and a total of 12 percent of findings and disorders were determined to be negated by NegEx. Table 7 shows the most common symptoms and most frequently negated symptoms in the physicians’ notes. The findings and disorders occurring more than 10 times in the text are also sorted on how large a proportion of them that is negated.

Table 7. The most frequent findings, disorders and negations found in the physicians’ notes.
Discussion

In this study, the efficiency of two existing tools for text mining of Swedish clinical text, i.e. for entity recognition and negation detection, was evaluated on a corpus of health records from patients with cervical cancer. The approach involved both manual and automated annotation of clinical entities, including negations. The investigation gave promising results and suggestions for further improvements. The issues studied relates partly to the problem of porting tools between subdomains of clinical text, and partly to the problem of inter-tool dependency when using a pipeline. As a result of this study, lists of clinical entities relevant to cervical cancer were created.

The term “sublanguage” is used to display that language in specialized domains exhibit characteristics that set them apart from general language21. However, clinical language is not homogeneous but consists of several specialized domains that exhibit the characteristics of sublanguages. The subdomain language will influence the creation of NLP tools for clinical text, as a tool relying on term statistics or semantics trained on one clinical note type have been suggested to not work as well on another. Clinical notes from different professions and specialties have been shown to cluster into readily distinguishable groups of lexical and semantic features.7

Here, a machine-learning tool called Clinical Entity Finder trained on clinical notes from a medical emergency unit was applied to notes in a Cervical Cancer Corpus. In both sub corpora, only notes written by physicians were used, as to avoid the further complexity of inter-professional sublanguages. Evaluation by comparing to manual annotation showed that precision was higher than recall for all of the annotated entity types, and manual inspection of tokens classified as findings, disorders, or body parts by the Clinical Entity Finder substantiates the precision of the tool. There were very few apparently faulty classifications; the lower recall was however often related to the tool being unable to classify expressions associated with cervical cancer.

NegEx classifies 12 percent of the findings and disorders in the data as negated; this is line with the findings of the manually annotated English clinical BioScope corpus that contained 14 percent negations. In another annotation study on clinical text from the internal medicine emergency unit, 19 percent of diagnosis expressions were found to be negated. The low F-scores for inter-annotator agreement on negated disorders was partly due to the disagreement between finding/disorder and not only because of disagreement on negation/non-negation. Error analysis did not indicate that the domain of cervical cancer affected the performance of NegEx. Instead the error analysis showed that NegEx gave false positives in some cases where an entity appears close to a negation trigger without actually being affected by it. False negatives where mainly the result of unusual negation triggers used in the physicians’ notes.

Findings and disorders associated with cervical cancer were often negated in the records, this is perhaps due to the fact that the patients in the corpus have known cancers and it is therefore of importance to document the presence or absence of such symptoms. Furthermore, as expected, statements regarding the general well being of the patient such as må brä (feels fine) or oro lig (worried) were frequently present in the records. These kinds of statements were actually seldom negated. Previous studies have found that affirmed and negated findings may be expressed on different levels of hierarchy. Here, this can be exemplified by the findings gynecological problems and signs of infection that were dominantly negated. However, when the patients had such problems, they were described as more fine-grained symptoms, such as bleeding, fever or pain, as opposed to the higher hierarchy general terms.

Manual annotation of clinical text is a time consuming and costly process and there is a need for domain experts or training of non-experts to obtain good quality annotations. Crowdsourcing is not an option due to the sensitive nature of the data. A tool that makes the annotation process easier is therefore valuable. It is also inevitable for human annotators to miss some entities when annotating, and the tools described here may increase the quality of the annotation in such cases.

Future work

Future work includes to extend the training data of the Clinical Entity Finder with the manually annotated cervical cancer health records, as this could be expected to improve the results on the cervical cancer domain by reducing the number of false negatives as indicated by the error analysis. The annotations performed in this study were on a relatively small amount of text. For the retraining of the tool, more annotation is needed, and a Gold Standard needs to be constructed by reviewing the annotations. The error analysis showed that a majority of false positives for
disorders and findings were incorrectly classified procedures or drugs; it could therefore perhaps be useful to include procedures and drugs as entity classes in the annotation to increase the precision of the Clinical Entity Finder. The symptoms found by the tools revealed that the same symptom was written in many different ways. This indicates the need for further usage of stemming, lemmatization and perhaps clustering of the found symptoms, to be able to draw more robust conclusions from our findings.

Conclusion

To our best knowledge, this is the first time cervical cancer narratives have been annotated both by human annotators and a machine learning based tool. By porting the Clinical Entity Finder to this new domain from the domain in which it was trained, the performance was reduced. Precision is still good, but the recall is decreased. This is expected and could be caused by the fact that the new domain contains patterns previously unseen by the tool.

The performance of negation detection was less dependent on the domain change, but since the negation detection is dependent on entities being found by the Clinical Entity Finder, its performance was more difficult to evaluate.

The Clinical Entity Finder was shown to be a useful tool for pre-annotation, since both annotators perceived it as making the annotation process more efficient as compared to annotating text without pre-annotation.

The clinical text found in health records is a promising source of information and the tools evaluated here could be a first step towards finding early symptom patterns in patients with cervical cancer.

Acknowledgements

We thank Maria Skeppstedt for letting us use the Clinical Entity Finder and we also thank Claudia Ehrentraut for her excellent initial study on cervical cancer text mining. This work was supported by the Nordic Information for Action eScience Center (NIASC); a Nordic Center of Excellence financed by NordForsk (Project number 62721). Machine Learning for Treatment Assignment: Improving Individualized Risk Attribution

1 University of Wisconsin, Madison, WI 2 University of Washington, Seattle, WA

Abstract
Clinical studies model the average treatment effect (ATE), but apply this population-level effect to future individuals. Due to recent developments of machine learning algorithms with useful statistical guarantees, we argue instead for modeling the individualized treatment effect (ITE), which has better applicability to new patients. We compare ATE-estimation using randomized and observational analysis methods against ITE-estimation using machine learning, and describe how the ITE theoretically generalizes to new population distributions, whereas the ATE may not. On a synthetic data set of statin use and myocardial infarction (MI), we show that a learned ITE model improves true ITE estimation and outperforms the ATE. We additionally argue that ITE models should be learned with a consistent, non-parametric algorithm from unweighted examples and show experiments in favor of our argument using our synthetic data model and a real data set of D-penicillamine use for primary biliary cirrhosis.

Introduction
Estimation of the risk of a disease attributable to an exposure or treatment is an important task in epidemiology and is typically determined using randomized controlled trials (RCTs). The average treatment effect (ATE)–the primary outcome of an RCT–is the average difference between treatment arms in the probability of the outcome, which is then used to recommend future treatments for individual patients. While ATEs are indicative of true treatment effects even in the presence of confounders, they have limited applicability for individual patients because we do not expect the same treatment effect in every person and diversity of effects goes beyond a population’s nonuniform prior risk. In addition, the ATE is population-distribution dependent, so it inherently lacks generalizability to alternative test distributions. Therefore, we consider modeling the individualized treatment effect (ITE), which is the effect of administering the treatment to a particular patient specified by a set of recorded features. Access to the ITE, in addition to the ATE, has many important clinical applications, with just one illustrated below.

Medication Use: Medications almost certainly have different effects in different individuals. For example, hormone replacement therapy treatment effect findings in RCTs and observational studies were of opposite sign for coronary heart disease, and advocacy of their use was rescinded when the RCT findings were released1. Yet, estrogen therapy is still the first line treatment among women experiencing hot flushes. This raises the question of whether ITE modeling can help determine subsets of patients who are still likely to receive benefit. Similarly, many drugs are taken off the market due to excess harm from adverse drug effects. Accurate ITE estimation could bring such drugs safely back to market for select subpopulations.

Currently, non-randomized epidemiological studies adopt classical statistical procedures, such as logistic regression (LR), in seeking to improve patient outcomes. However, machine learning has developed many alternative models for conditional probability distributions (CPDs) with numerous advances achieved. These advances should be leveraged in estimation of the treatment effect—a crucial epidemiological outcome of interest. Our work proposes the use of non-parametric algorithms possessing consistency results in place of logistic regression because of their theoretical ability to accurately recover the CPDs.

In this work, we show the value of ITE over ATE as well as the use of conditional probability models over logistic regression, using both synthetic and real data. We demonstrate our ability to recover the true ITE in synthetic data, and we show the generalizability of the conditional probability model to alternative population distributions of increasing Kullback-Leibler (KL) divergences. We also show that a conditional probability model learned with a consistent, non-parametric algorithm achieves a lower mean squared error (MSE) estimate of the ITE than logistic regression. Furthermore, we show that the conditional probability model produces a better estimate of the ITE than logistic regression on a real RCT data set of D-penicillamine use for primary biliary cirrhosis. Additionally, we show that learning from propensity-score matched examples and stable inverse probability of treatment-weighted examples do not improve over unweighted examples for making ITE prediction when only observational data is available. Thus, by casting treatment effect estimation in a machine learning framework, we introduce ways machine learning can be
used to develop improved, personalized-risk estimates and treatment recommendations.

**Background**
Randomized controlled trials are the gold standard for estimating the average treatment effect. They randomize patients to different treatment arms and measure the rate or probability of an outcome. The treatment arm with the highest success rate determines the preferred treatment, and the conclusion is that future patients who fit the entry criterion of the study should all get the preferred treatment. Randomization is crucial to balance confounders, which are covariates that lead to the outcome and are associated with the treatment. Randomization also balances confounders not measured in the study, so the conclusion is free of confounding bias in expectation.

In general, one cannot observe both “potential outcomes”, i.e., know what will happen to a specific patient under each treatment arm. The treatment that is given elicits the “true” outcome, and the treatment(s) not given elicits the “counterfactual” outcome. The counterfactual outcome is impossible to measure, but with randomization and the assumption that patients are drawn from an underlying population distribution, the expected outcome of patients assigned to a treatment arm is the same as the expected outcome of patients with the same treatment, true or counterfactual. Thus, RCTs provide a recommendation about the treatment effect for every treatment arm in the study for every patient.

**Confounding in Observational Studies:** The RCT, however, is impractical or infeasible for many exposure-outcome pairs. For example, randomization to a harmful treatment, such as smoking, is unethical. In such cases, observational studies are used to derive risk attribution statements. These include studies that use known-confounder-modeling, propensity scoring, inverse probability of treatment-weighting, and doubly-robust estimators. The two main ideas in these methods are to (1) adjust for confounders by modeling them, and (2) manipulate the population distribution so that the treatment is independent of confounders given the outcome. These methods rely upon modeling, but cannot do so effectively if they are missing important contributors to their model: the unobserved confounders. Thus, one key assumption in all of these methods is that there are no unobserved confounders (NUCA), which is difficult to determine in practice. Also, in most of these approaches, a model is assumed for the CPD of the outcome given the exposure and covariate. In these cases, the counterfactual outcomes, which are never observed, are assumed to follow the model CPD.

A second assumption made in clinical studies is the exclusion of intermediate variables–covariates that are on the causal pathway from the treatment to the disease. If included, the treatment effect is underestimated because the effect can be “explained away” by the intermediate variable. The exclusion of intermediate variables decreases the richness of the model, as the intermediate variable may also modify the treatment effect, and analyses that acknowledge and integrate this information exist.

**Individualized Treatment Effect:** One critical drawback of all these methods is that they seek to calculate the average treatment effect, when most applications of risk attribution really desire the ITE. The ITE provides the effect per individual instead of a population-level effect, and information about future individuals can be leveraged in determining optimal treatment choices. Unlike in ATE estimation though, acquiring sufficient counts to estimate the counterfactual ITE outcome is unachievable for any moderate-sized feature vector because the number of possible feature states is exponentially large. Therefore, a modeling approach to estimate the counterfactual outcome becomes necessary. These can be the same CPD models used in pseudo-randomized ATE estimation, e.g. logistic regression, but in the Methods section we will discuss two reasons to adopt other machine learning models: non-uniform treatment recommendations and non-parametric consistency.

The call for adoption of the ITE is not new, and the limitations of applying population-average effects on individuals has been noted. The ATE or relative risk is stated as the primary outcome, usually followed by a secondary analysis of the heterogeneity of treatment effect. As mentioned in Hayward et al., performing subgroup treatment effects is usually more effective in risk-stratified subgroups derived from multivariate analyses than in subgroups defined by individual covariates, and these methods have been adopted for approximating individualized treatment effects. While these methods do improve finer-grained treatment effect estimates, factors beyond the outcome risk may influence the treatment effect and can be utilized when modeling the ITE.

Modeling of the individualized treatment has been implemented in several studies. Qian et al. develop the framework of reward modeling and using model predictions to estimate individualized treatment rules (ITRs). Our work is related but instead makes statements about the utility of the ITE, the generalizability of the ITE, and the preference for using unweighted observational data for ITE estimation, all with simulations to illustrate these advantages. Our simulations
based on synthetic data have access to a ground truth ITE, which we use to assess our ITE estimations.

However, it is possible to assess the benefit of ITE without access to ground truth. Vickers et al.\textsuperscript{13} provides an unbiased method to estimate the advantages of using the ITE recommendation over the ATE recommendation using existing RCT data. They show that by counting outcomes in the subset of patients where ITE- and ATE- treatment recommendations disagree, the expected difference in treatment recommendations is estimated. Our experiments include such analyses to show that the ITE-recommendation can be estimated without access to the counterfactual outcomes. Unfortunately, this method can be severely underpowered in the case that the ITE- and ATE- treatment recommendations are highly similar, and a power calculation analysis to determine recruitment size would be helpful. Alternatively, a new RCT study could be implemented by randomizing to ITE- and ATE- treatment arms.

The methods we adopt do not directly optimize the individualized treatment recommendation. Instead, we model the conditional probability distribution, and then the differences in probability are determined using the estimates for the treatment effect of the true and counterfactual treatments. Zhao et al.\textsuperscript{14} develop a method to directly optimize for the ITR under a surrogate loss function from RCT data. While this method produces individualized recommendations, we believe a model should also provide treatment effect estimates under each treatment arm, because the treatment effect itself is critical information clinically. Also our methods do not require RCT data and scale to multiple treatment arms and factorial designs.

**Methods**

We describe ITE modeling below. Let the ITE for an outcome $y \in \{0, 1\}$ of a patient with features $v$ given treatment $u \in \{0, 1\}$ be the difference in estimates: $p(y = 1 | u = 1, v) - p(y = 1 | u = 0, v)$. The key assumption made in these modeling approaches is that both potential outcomes—the true outcomes $y_{\text{true}}$ and the counterfactual outcomes $y_{\text{cf}}$—come from the CPD model, that is, $p(y_{\text{true}} | u, v) = p(y_{\text{cf}} | u, v) = p(y | u, v)$ for all $u$ and $v$. The interpretation of the ITE is only causal if the no unmeasured confounders assumption (NUCA) is made; otherwise, it is just a statement about the difference in outcome probability given a new patient described by $(u, v)$.

If we have a correctly specified model and NUCA holds, for any new patient, we have their ITE that guides our treatment choice. This statement is notably population-distribution free and thus can generalize to arbitrary population distributions of $(u, v)$. The ATE does not have this characteristic; its calculation is dependent on the distribution of $(u, v)$ so its application should be limited to populations with similar covariate distributions unless the treatment effect is believed to be uniform.

Recalling that the application of the RCT-recommended treatment suggests that every patient should receive that treatment, a logistic-regression-based model similarly provides a uniform decision. Its decision will be in agreement with the sign of the treatment parameter. However, in many cases, and particularly in those where the treatment effect has small magnitude but high variance, the optimal treatment decision is nonuniform. Thus, we adopt machine learning methods which can estimate the CPD while also providing nonuniform treatment choices. In particular, we use AdaBoost because it has consistency results and is a non-parametric learning algorithm\textsuperscript{15,16}. In other words, AdaBoost will recover the correct CPD given enough examples, and will do so regardless of the train $(u, v)$ distribution provided proper support.

Table 1: Discussed methodologies with positive and negative characteristics in green and red respectively. ATE average treatment effect, ITE individualized treatment effect, RCT randomized controlled trial, PSM propensity-score matching, (s)IPT-W (stabilized) inverse probability-of-treatment weighting, LR logistic regression, CPD conditional probability distribution, NUCA no unmeasured confounders assumption.
With the adoption of a non-parametric learning algorithm comes the parametric/non-parametric learning trade-off. Parametric models may require smaller sample sizes to learn effectively but are not consistent if misspecified; non-parametric models may require larger sample sizes to achieve good CPD estimates but have arbitrary joint distribution consistency results.

Recall that propensity-score matching (PSM) and (stabilized) inverse probability-of-treatment weighting ((s)IPT-W) are methods to produce pseudo-randomized data for the estimation of the ATE\(^3,4,5\). With ITE as the target statistic, these methods become less desirable. In modeling the CPD, PSM and IPT-W weighting reduce the effective sample size, reducing our numbers for estimation. Thus under the modeling assumption and the goal of modeling ITE, we argue for unweighted CPD estimation. Table 1 compares and summarizes the advantages and disadvantages of study methods related to ATE and ITE estimation.

**Experimental Approach**

In this section, we restate the claims and reasoning in support of the individualized risk framework and provide ways to confirm them experimentally using synthetic data with access to ground truth, or using observational or RCT data.

As already noted, there is a strong argument for estimating the ITE over the ATE because the ITE is applicable for patient-specific recommendations as opposed to ATE-based, population-average recommendations. With correct specification and NUCA, the ITE is also generalizable to arbitrary population distributions, though it is harder to estimate than the ATE. The value of the ITE recommendation can be compared against an alternative–for example, ATE recommendation–using the subset of randomized patients where treatment recommendations differ\(^13\). With these methods, we test the hypothesis of ITE superiority and illustrate the benefits of ITE estimation on synthetic data.

We suggest that, in preference for generalizability of study outcome, the conditional probability distribution \( p(y|u, v) \) should be modeled with non-parametric learning algorithms. That is, our goal should be to learn the correct \( p(y|u, v) \) irrespective of the distribution \( p(u, v) \) because future data distributions \( p'(u, v) \) may be different. Non-parametric learning algorithms achieve independence from \( p(u, v) \) in the limit of increasing data. We use a synthetic dataset to empirically characterize the recovery of the ITE varying the training set data size and compare the performance of parametric and non-parametric learners varying the similarity of train and test set population distributions. We also use a real RCT data set to compare the treatment assignment policies of parametric and non-parametric learners in the presence of a substantial average treatment effect. Additionally, we use synthetic data to compare ITE estimation generalizability for parametric and non-parametric learners when the test set distribution \( p(u, v) \) varies from the training set distribution, though the conditional probability distribution \( p(y|u, v) \) remains the same. We also show experimentally that estimating \( p(y|u, v) \) directly from the original data distribution outperforms analogous estimators from propensity-score-weighting and similarly to stabilized inverse probability-of-treatment weighting.

Finally, we discuss applications of the conditional probability distribution modeling approach. Numerous concerns have been voiced about the appropriateness of observational data as a data source for the effect of treatments because confounding can bias the statistical interpretation. With free reign on the covariate definitions in observational studies, we may have access to highly-correlated or even logically-related covariates, such as "ever smoked" and "current smoker," in our analysis. We opt to include such covariates for richness of representation that can lead to better estimates of \( p(y|u, v) \), but must adapt our interpretation of "intervention" to specified multivariate changes instead of a (univariate) change of treatment state. We discuss several desired conditions when defining the set of "treatment" states and propose methods to provide interpretable recommendations when the space of "treatment" states is large.

**Experiments**

We first define a synthetic model of myocardial infarction (MI) with thirteen variables: age, gender, smoking status, HDL level, LDL level, diabetes, family history of cardiovascular disease (CVD), blood pressure, history of angina, history of stroke, history of depression, statin use, and MI. For simplicity, each variable is binary. The joint probability distribution is defined by the causal Bayesian network in Figure 1 with hand-crafted conditional probability distributions for each variable informed by medical expertise. Observational data are sampled directly from this Bayesian network, while interventions can be simulated by removing incoming edges to the intervention variable and specifying the Bernoulli distribution parameter. Thus, we simulate data from an RCT of statin use by removing the edge from LDL to statin and using a CPD for statins with equal probability of “yes” and “no” to define our RCT data distribution.

The question we seek to answer for our synthetic model is the effect of statin use on heart attack or MI. We test
the per-patient recommendations for or against statin use from logistic regression and boosted trees against the ATE recommendation of always prescribing statins. Testing uses data generated from our synthetic, randomized distribution and evaluation is performed using both the RCT method of Vickers et al. \(^{13}\) and by comparing the predicted ITE to the ground truth ITE calculated exactly from the Bayesian network. Unless otherwise specified, train and test data are generated from the RCT distribution where the LDL to statin edge is removed from the network. When learning our AdaBoost and logistic regression models, we need to ensure the intermediate and confounder assumptions described in the Background section are met. Since we are using synthetic data, there are no unobserved confounders outside our model. However, diabetes is on a causal pathway from statins to MI, so we exclude it from the features available to our models.

With our synthetic model we seek to characterize estimation of the ITE for each method by looking at error modes of each model and producing learning curves for the models as a function of training set size. To test for applicability to an arbitrary test population distribution, we alter the test distributions by changing CPDs for variables with no parents in the causal DAG. Finally, to evaluate ITE estimation from observational data, we use training set data from the observational Bayesian network and compare the estimation from the unweighted training set with estimation using altered data sets via propensity-score matching and stabilized inverse probability-of-treatment weighting.

To validate our claims on real data, we run experiments using trial data for the treatment of primary biliary cirrhosis (PBC) of the liver from the Mayo Clinic \(^{17}\). The trial covered a ten-year period and randomized patients across treatment with a placebo versus treatment with D-penicillamine. The data set includes 16 variables, including demographic

</table>
information like age and sex, as well as various lab tests such as serum albumin, serum cholesterol, and triglycerides (see Table 2). The question we seek to answer for this RCT dataset is the effect of D-penicillamine use on three-year survival. For the three-year survival period, the data set is censored to 288 patients, with 146 in the treatment group and 142 in the placebo group. At the end of three years, the treatment group experienced 27 deaths out of 146, whereas the placebo group experienced 32 out of 142. The trial thus demonstrates an average treatment effect of around 4% reduction, indicating a number needed to treat (NNT) of 25, in death rate at three years.

With the PBC trial data, we seek to compare the estimation of the ITE for each method against the ATE recommendation to treat all patients. Furthermore, given the strength of the average treatment effect, we compare the number of times each method suggests that a patient receive no treatment as opposed to the ATE recommendation. We estimate the average ITE versus ATE and number of untreated patients for each method by running 100 replicates.

We use the ‘ada’ package implementation of AdaBoost in R to learn the boosted forest\(^\text{15}\text{,}\text{16}\). Though the consistency guarantees for AdaBoost require the number of iterations to grow linearly with the training set size\(^\text{18}\), we use the
square root of the training set size to reduce the computational burden. Otherwise, we use the default settings from the 'ada' package. Logistic regression models are trained using the 'glm' function of R.

Results

Figure 2 shows the utility of adopting the ITE recommendation over the ATE recommendation on our synthetic model. We want to lower the risk of MI, so a negative difference between ITE and ATE is desirable. From Figure 2a, we see that the adoption of the ITE recommendation, as calculated from the AdaBoost model, lowers the probability of MI by 0.01 on average, provided sufficient training data. That is, the number needed to treat is about 100, so treating 100 patients with the ITE-recommended treatment results in one less MI on average than the ATE-recommended treatment of giving everyone statins. Only AdaBoost is able to provide an improved recommendation because of its ability to accurately estimate the conditional probability distribution. Since there are no interaction terms in our logistic regression model, the recommendation converges to the ATE recommendation of giving everyone statins, resulting in the observed difference of 0 for larger training set sizes in Figure 2.

Figure 2b shows the estimated expected difference in probability of MI between ITE- and ATE- recommended treatments among patients where the recommendations disagree on treatment choice. We see that the ITE recommendation lowers the probability of MI in this subset by about 0.02, or a NNT of 50. The upturn for AdaBoost as the training set size approaches 100,000 is likely due to correctly identifying more patients with small benefits from not taking statins. This dilutes the ITE- and ATE- difference among those patients where the recommendations disagree, but the population-wide probability of MI, which is the primary value of interest, continues to decrease.

Figure 3 shows the utility of adopting the ITE recommendation over the ATE recommendation on the PBC trial data. We want to lower the rate of death over a three-year period, so a negative difference between ITE and ATE is desirable, just as it is with our synthetic model. In Figure 3a we see that neither the AdaBoost model nor the logistic regression model outperform the ATE recommendation to treat all patients. While we would prefer to see the ITE outperforming the ATE, this result is not altogether surprising given the effectiveness of treatment. We do, however, see that the AdaBoost model roughly matches the ATE and outperforms the logistic regression model as we hypothesize and demonstrate repeatedly with our synthetic data. In Figure 3b we show the average number of patients for which each model recommends no treatment. The AdaBoost model rarely recommends no treatment, showing that it has effectively learned the treat-all policy, whereas the logistic regression model frequently recommends no treatment.

Learning curves for logistic regression and AdaBoost are shown in Figure 4a. These curves show mean-squared error of the ITE predictions versus training set size. As we expect, the parametric logistic regression converges to a non-zero error because the model is misspecified (since the ground truth model is not log-linear in the exposure and covariates). The error of AdaBoost, however, continues to decrease towards 0 as training set size increases, showing very accurate estimation of the ITE is possible with sufficient data. AdaBoost's approach toward 0 error is in line with the non-parametric consistency results of Bartlett et al.18.
which is exactly LDL, HDL, and smoking in the logistic regression would improve its performance. AdaBoost has the capability to simulate applying results to different populations by adjusting the prevalence of the five variables in our Bayesian network. Our final experiment is on the generalizability of ITE predictions for AdaBoost compared to logistic regression. We simulate applying results to different populations by adjusting the prevalence of the five variables in our Bayesian network (see Figure 1) with no parents: age, gender, HDL, depression, family history of CVD. We train on our default RCT data, with marginals shown in Figure 1, but test on modified RCT data with different prevalences of the aforementioned variables. Thus, we have changed \( p(v) \), but \( p(y|u, v) \) remains the same, so an accurate prediction of CPD, which is exactly \( p(y|u, v) \), should handle the changing test distribution gracefully. Figure 4b shows that the MSE does not change much.

To further investigate the errors in ITE prediction, we show the predicted ITE versus the ground truth ITE (as calculated from our Bayesian network) in Figure 5. Additionally, we plot the ATE which effectively predicts an identical treatment effect for all patients. The goal is to have predictions as close as possible to the true value, i.e., to have points as close to the \( y = x \) line as possible. In agreement with the results of Figure 4a, AdaBoost makes better ITE predictions than logistic regression and improves noticeably from 10,000 to 100,000 examples. For logistic regression (top), all ITE estimates will be above or below the line \( y = 0 \) because the model assumes that a single coefficient determines the direction of the effect. The four groupings of points extending down (at various angles) from the origin correspond to various settings of the variables LDL, HDL, and smoking. This suggests that including interaction terms among statins, LDL, HDL, and smoking in the logistic regression would improve its performance. AdaBoost has the capability to learn arbitrary interactions and can provide individualized recommendations, though the errors remain greater than zero as shown in the bottom of Figure 5. Indeed, some of the groupings of points lie off the \( y = x \) line also correspond to certain patient subpopulations for which the ITE is consistently misestimated. We expect, due to the consistency of AdaBoost, that these errors will decrease as more training data is available.

The effect of different data-weighting and matching schemes is shown in Figure 6. The recovery of the CPD model, and thus the ITE, requires the fewest examples when leaving the examples unweighted or using stabilized inverse weighting. While propensity score matching produces worse estimates of ITE, there is no benefit for using stabilized inverse weighting over no weighting for this task. One important consideration is that our data set includes some patients without elevated LDL who take statins, motivated by the suggestion that there could be therapeutic benefit of statins even in borderline hypercholesterolemia. However, in a data set with fewer normal-LDL statin users, propensity-score matching and particularly stabilized inverse weighting will impair the CPD model, because it will attach large excess weight to few examples.

Our final experiment is on the generalizability of ITE predictions for AdaBoost compared to logistic regression. We simulate applying results to different populations by adjusting the prevalence of the five variables in our Bayesian network (see Figure 1) with no parents: age, gender, HDL, depression, family history of CVD. We train on our default RCT data, with marginals shown in Figure 1, but test on modified RCT data with different prevalences of the aforementioned variables. Thus, we have changed \( p(v) \), but \( p(y|u, v) \) remains the same, so an accurate prediction of CPD, which is exactly \( p(y|u, v) \), should handle the changing test distribution gracefully. Figure 4b shows that the MSE does not change much.
Figure 6: Learning curves for AdaBoost trained on observational data. Test set ITE mean-squared error as a function of training set size is shown comparing training from unweighted examples (None), propensity-score matched samples with a 1:1 ratio (PSM), and stabilized inverse probability of treatment weighted examples (sIPTW). 95% confidence intervals are calculated over 100 replications.

Discussion and Future Work

Validation on Real Data: Our work highlights the machine learning potential for individualization in clinical scenarios. However, the work we have presented requires empirical justification in several directions. First, while we have provided empirical analysis on one real RCT data set we seek to apply our framework to more clinical data: both RCT and observational. In these settings, we do not have access to the ground truth ITE. Nevertheless, as in Figures 2 and 3, we can adopt the approach in Vickers et al.\textsuperscript{13} to compare outcomes from ITE and ATE recommendations. For rigorous evaluation, we must evaluate on several populations with varying covariate distributions. A characterization of which $p(u, v)$ distributions provide reliable ITE recommendations is critical as well. For example, there may be more uncertainty for patients under-represented in the training set, especially with limited data.

Statistical Theory: In addition, a deeper theoretical understanding of the algorithms and evaluations is necessary. For example, investigation of required training set sizes for non-parametric learning algorithms to outperform parametric algorithms, and logistic regression in particular, would be valuable. A characterization of the number of examples needed to move past the mean squared error of the logistic regression for a given task is important as a factor in determining when we should recommend the non-parametric model ITE instead of the ATE. Additionally, improved statistical understanding of the Vickers et al.\textsuperscript{13} method is critical. Two such statistical properties of particular interest are (1) a measure of the uncertainty in the differences calculated by the Vickers et al\textsuperscript{13} method and (2) power calculations to determine the necessary sample sizes to detect meaningful differences between ATE and ITE.

Epidemiology Methods: Critical factors preventing the automatic use of EHR data for risk attribution are variable definitions, confounders, and intermediate variables. For a pure prediction problem, precisely-defined variables that carry relevant information can improve performance, provided a large enough training set. For risk attribution, however, exclusion of a confounder or inclusion of an intermediate variable can result in biased estimation of both the ITE and ATE. This occurs with ITE prediction from logistic regression or non-parametric learners because the risk is, often arbitrarily, divided between the exposure and the intermediate variable causing inaccurate estimation of the exposure risk. However, we should not simply accept a regime that excludes intermediate variables because inclusion of intermediate variables may enhance our modeling of the conditional probability distribution.

Epidemiological study design often opts for the removal of variables that would actually improve the conditional probability model. We suggest two approaches to explore. First, for interventions, we can define the scope of their influence as a probabilistic change to multiple variables. For example, a diabetes intervention could be represented by the replacement of variable values for “rosaglitazone”, “fasting blood sugar,” and “HbA1c”. Then we can model the effect of intervention by comparing probability of outcomes under intervention or no intervention while richly modeling the conditional probability distribution. Second, a timeline-based analysis where the effect of the intervention...
on apparent intermediate variables, as well as the outcome of interest, can be modeled over time might allow all variables to be leveraged for prediction without hindering risk attribution.

Conclusion

In this work, we illustrated the parallels between the standard clinical study framework designed to determine the ATE and the burgeoning clinical study framework designed to determine the ITE. We highlighted shortcomings of the ATE; first, that the ATE is an average outcome, when in practice we usually care about the ITE for future patients, and second, that the ATE is population-distribution dependent. We then discussed modeling of the ITE. Notably, logistic regression can only recommend one treatment arm if we exclude non-linear and exposure-covariate interaction terms because the coefficient for exposure is either negative or non-negative. Furthermore, unless correctly-specified, logistic regression is not a consistent learning algorithm, so we cannot always recover the true conditional probability distribution, even from large populations. Instead, we adopted another popular framework, boosted trees. We showed that the forest-based ITE outperformed the ATE on a synthetic problem of MI prediction using binary variables, and that the forest-based ITE outperformed logistic regression-based ITE on a real problem of primary biliary cirrhosis treatment with D-penicillamine. Additionally, we showed that the use of propensity-score matching and inverse-probability-of-treatment weighting failed to improve the learning of the conditional probability distribution, suggesting that unweighted samples should be used for learning a model of the ITE. Finally, we showed that the forest-based ITE better generalized to different test set distributions than the logistic regression-based ITE. Modeling of the ITE has large theoretical advantages, though robustness guarantees and validation of its performance should be established before large-scale clinical deployment. A few sources of validation include replication studies and heterogeneity of treatment effect analyses using ITE model strata.

Abstract
Family health history (FHx) is one of the most important risk factors for disease. Unfortunately, collection and use of FHx is under-utilized in the clinical setting. Efforts to improve collection of FHx have had minimal impact. A novel approach to collect FHx using social networking capabilities is being explored. We conducted a nationwide survey of 5,258 respondents to 1- assess the interest in using an online social network for FHx, 2- identify if such a tool would have clinical utility, and 3- identify notable trends and potential concerns. We found survey respondents to be very supportive of the proposed approach and interesting trends related to age, education, and race were identified. Results from this survey will be used to guide future research and development of a proposed FHx social network application.

Introduction
Family health history (FHx) is one of the most important risk assessment resources to help clinicians prevent and control disease. By knowing a patient’s heritable risks, a clinician can personalize preventative and risk-mitigating strategies, such as increased screening, prophylactic surgery, risk-reducing therapeutics, and lifestyle changes. FHx is among the strongest risk factors for disease. For instance, patients with three or more first degree relatives with breast cancer have a 4-fold increased risk for breast cancer. Even a single first degree relative with colon cancer yields a 5-fold increased risk. Clinicians empowered with this information can personalize preventative care to reflect the increased risks of the patient. For example, colonoscopies and mammograms could be started at an earlier age and at increased frequency for patients at increased risk for colon or breast cancer, respectively. Furthermore, FHx is becoming a critical component of genomic medicine as the FHx is often used by genetics professionals to interpret genetic test results. Because FHx plays a significant role in risk assessment and genomic interpretation, its importance to controlling and preventing disease is considerable.

Even though FHx is a valuable resource to disease control and prevention, it is largely underutilized in the clinical setting. Studies have shown that clinicians typically discuss FHx with half of new patients and less than a quarter of return patients. Even among patients diagnosed with breast or colon cancer, two diseases known to have strong hereditary components, less than half of clinicians discussed FHx. A good FHx takes about 20-30 minutes to complete; however, clinicians typically only have a few minutes to discuss FHx with their patients. There simply is not enough time during a busy clinic schedule to collect and analyze a 3-generation family pedigree, the gold standard for FHx information. Furthermore, even if a clinician had enough time to record a detailed FHx, a patient’s self-reported FHx is often suboptimal. For example, the accuracy of self-reported FHx ranges widely, from 30%-90%, depending upon the degree of family relatedness and the reported disease. In summary, clinicians lack the time to record what often will be an inaccurately reported FHx from their patients.

Current Approaches to FHx Collection
To overcome these challenges, a number of groups have developed paper-based and web-based tools to help patients organize their FHx outside the clinical visit. The premise of such an approach is two-fold: first, patients have greater access to their FHx information outside a clinic visit, thus allowing them to collect relevant, and hopefully more accurate, FHx without time constraints. Second, and very importantly, when a patient returns to a clinic visit with a completed FHx in hand, the clinician can focus on actually using the FHx information to guide care. The most prominent of these FHx tools is the Surgeon General’s web-based My Family Health Portrait (https://familyhistory.hhs.gov). While small focus groups and surveys have demonstrated that patients and clinicians generally accept the use of such FHx tools, they are poorly adopted outside of research settings. Only about 2% of Americans have ever used a web-based FHx tool. We believe this is largely because the patient alone is responsible to gather, record, and assure the completeness and accuracy of all his or her FHx information with current FHx tools, a substantial burden placed solely on the patient. Moreover, these FHx are usually just basic interfaces to document FHx information; there is little intrinsic incentive to motivate adoption and usage. Also, there is a lack of collaborative support for family members, meaning each family member typically enters redundant family health information in
parallel with other family members- a waste of energy and knowledge. Moreover, even though patient-collected FHx using one of these tools has a fairly good (67%-100%) concordance with a FHx collected by a genetic counselor, this tool does not preclude inaccurate recollection (“I think Aunt Jane had breast cancer, or was it stomach cancer?”). Given the known inaccuracies of patient-reported FHx and the less-than-perfect concordance with in-person FHx interviews, we estimate that only about half of patient-generated FHx information using FHx tools will be correct. Any significant deviation from the true FHx interferes with disease risk assessment and genomic interpretation. Indeed, the issue of FHx reliability and accuracy must be addressed by any FHx collection tool in order to use FHx information effectively to improve patient care. Given the importance of FHx and its inherent challenges, we need more effective and accurate tools to help patients collect their FHx.12

A Novel Approach to FHx Collection

We believe that online social networking is a novel and innovative approach that can improve the collection of FHx. Over the past decade, online social networks have dramatically changed interpersonal communication and spreading information at unprecedented speeds; we plan to leverage benefits of online social networking to improve the collection and use of FHx. Indeed, by directly linking family members together to share health information via an online social network, we believe it will (1) engage more individuals in collecting a FHx as a result of cooperative behavior cascades within a family;1> (2) produce a more complete and accurate FHx because the ‘wisdom of the family’ corrects mistakes and fills in gaps in FHx knowledge;14 and (3) facilitate social support between family members, leading to positive behavior change and healthy decision making.15 While online social networks are available for families (e.g. eFamily.com) and for health (e.g. PatientsLikeMe.com), there are no online social networks that combine families and health. Using social networking to collect FHx is an untapped opportunity to improve the prevention and control of cancer, and may be more effective than current FHx tools in helping individuals collect their FHx. To address this important need, we are developing an online FHx social networking called ItRunsInMyFamily.com (http://ItRunsInMyFamily.com), which will help individuals to link up and share health information with their family members. ItRunsInMyFamily.com will be like Facebook, but designed specifically for sharing health information among relatives. See Box 1 for a description of the features and capabilities of ItRunsInMyFamily.com. Of note, the combination of health information, online social networking, and family relations raises an interesting mix of issues surrounding privacy, laws, and ethics. Nevertheless, efforts are currently underway to further explore these ethical and legal issues needs and determine how to best implement available technologies, techniques, and approaches to protect the security, privacy, and confidentiality of users’ health information.

Box 1. A summary of proposed features and capabilities available within ItRunsInMyFamily.com

End users are critical to the success and utility of any application. It is imperative to demonstrate an interest in ItRunsInMyFamily.com among potential end users. Therefore, we conducted a nationwide survey among the U.S. population to assess relative interest in ItRunsInMyFamily.com, to identify trends, and to highlight potential concerns or issues. Results from this survey will be used to guide future research and development, as well as establish a case for ongoing efforts and support for ItRunsInMyFamily.com.

Methods

We used SurveyMonkey Audience (Palo Alto, CA) to produce a nationwide, demographically balanced representation of the United States population, ages 18 and older. SurveyMonkey Audience, commonly used in academic research, has participants complete a demographic profile which includes sex, race/ethnicity, age, education, income, and regional location of the respondent. This demographic information is then used to randomly recruit a population balanced to match the general U.S. population.1> Additionally, the survey results were weighted by demographics to match the 2013 U.S. Census Bureau Population Survey relative to age, race/ethnicity, sex, and education. To maintain
the integrity of response data, SurveyMonkey Audience limits the number of surveys a member can participate in per week, rewards members with non-cash incentives (charitable donations and sweepstakes entries), and regularly benchmarks the members.

The survey consisted of a total 18 questions. Nine questions were assessing respondents awareness and use of FHx (these results published elsewhere). After a short description of ItRunsInMyFamily.com (see Box 2), seven Likert scale questions assessing the likelihood (not likely, slightly likely, moderately likely, quite likely, and extremely likely) of using and acting upon information in ItRunsInMyFamily.com. Additionally, we asked two Likert scale questions assessing the comfort (not comfortable, slightly comfortable, moderately comfortable, quite comfortable, and extremely comfortable) with planned privacy and security approaches to be used by ItRunsInMyFamily.com (asked after a brief overview of the approaches ItRunsInMyFamily.com will use to protect the privacy and confidentiality of its users [see Box 2]). The complete survey including questions and descriptions can be found at (https://www.surveymonkey.com/s/YHHRW7H). The survey questions and informed consent were approved by the Institutional Review Board (IRB) at the Medical University of South Carolina (MUSC).

Researchers and clinicians at the University of Utah and the Medical University of South Carolina are developing a new social networking website for family health history called ItRunsInMyFamily.com. ItRunsInMyFamily.com will help you gather and organize your FHx by allowing you to enter your own health information and then link up to share health information with your relatives. It is like Facebook, but for your family's health. With ItRunsInMyFamily.com, you will be able to:

- Record and maintain your personal health history all in one place online
- Link up with relatives and see what health concerns they have (or had)
- Comment and discuss health issues that run in your family with your family members
- Receive personalized recommendations based upon your personal and family health risks
- Share your family health history information with your doctor

Box 2. ItRunsInMyFamily.com introductory survey text

Privacy and security of one's health information is often brought up as a potential concern to future users of ItRunsInMyFamily.com. As a result, ItRunsInMyFamily.com developers plan to include a number of safeguards to protect the privacy, security, and confidentiality of its users. For example, ItRunsInMyFamily.com will:

- Prevent unauthorized access to your personal or family health information from individuals, companies, or entities;
- Allow you to control access to your personal health information to specific relatives. For example, you could prevent your Uncle Jack from knowing that you have asthma;
- Allow you to control what is shared about yourself to a family member's doctor;
- Use encrypted transmission and encrypted storage of all information provided; and
- Use HIPAA-compliant servers to store your health information.

Box 3. ItRunsInMyFamily.com privacy & security text

Survey data were analyzed using R 3.1.1 and SAS 9.3 (SAS Institute, Cary, NC). Descriptive statistics were used to summarize the results. Multiple logistic regression was employed in several univariate models to assess differences in covariates with respect to different survey response items of interest. Primary covariates of interest include age, gender, education level, and ethnicity, each weighted to the 2013 US Current Population Survey. For ease of interpretation in regression modeling, the original Likert scale responses were dichotomized to ‘more likely’ (extremely, quite, and moderately) vs ‘less likely’ (slightly and not at all). For direct comparison of scenarios regarding the subset of questions pertaining to “How likely would you be to use ItRunsInMyFamily.com if...?”, a generalized estimating equation (GEE) framework was utilized to control for correlated responses among individuals across the four response variables. We strive for a parsimonious comparison of the scenarios; given the analysis of trends showed relatively equal changes in direction across scenarios within levels of each covariate, the covariate adjusted GEE model was fit without interactions to evaluate how they compared, which provides relatively unbiased inference on population level changes in likelihood of using ItRunsInMyFamily.com across the four scenarios.

Results

A total of 5,258 subjects (of 5,438 invited; a 96.69% participation rate) participated in the survey between October 6 through 17, 2014. The demographics of the respondents are reflective of the U.S. population. Women represent 51.6% of respondents, 21.7% of respondents were between the ages of 18-29, 25.7% between 30-44, 27.1% between 45-59,
and 25.5% over the age of 60. ‘White/Caucasian’ represent 66.4% of respondents, 15.1% were ‘Hispanic/Latino’, 12.3% were ‘Black/African American’. 41.7% of respondents had a high school education or less.

**Would you use ItRunsInMyFamily.com?**

We found that **76.8%** of respondents were likely (7.46% extremely, 18.5% quite, 26.7% moderately, and 24.1% slightly) to use ItRunInMyFamily.com to collect and organize their FHx (baseline scenario). When asked their likelihood of collecting, organizing, and sharing their FHx using ItRunsInMyFamily.com if a doctor encouraged its use, **82.9%** of respondents were likely (13.4% extremely, 26.3% quite, 24.9% moderately, and 18.3% slightly) to use it. Similarly, **82.9%** of respondents were likely (13.1% extremely, 27.4% quite, 25.9% moderately, and 16.5% slightly) to use ItRunInMyFamily.com if a family member invited them to join and share their health information. Interestingly, **87.6%** of respondents would likely (31.9% extremely, 29.1% quite, 17.3% moderately, and 9.4% slightly) use ItRunsInMyFamily.com if they were invited by a family member who was suffering from a health because it might help his/her care or treatment. Notably, nearly two-thirds (61%) of respondents would be ‘extremely’ or ‘quite’ likely to use ItRunsInMyFamily.com in this case. A Chi-square test of weighted frequencies indicates these differences in the likelihood of using ItRunsInMyFamily.com across the various scenarios is statistically significant (p <0.001), indicating the distribution of responses to be different depending on the reasoning given to use the website. See Figure 1 and Table 1 for a summary.

Multiple logistic regression models showed some interesting trends relative to age, gender, and ethnicity. See Table 2. We found that compared to the youngest age group (18-29 years old), respondents older than 30 years were at greater odds (30-44 OR: 1.59, p<0.001; 45-59 OR: 1.50, p<0.001; 60+ OR: 1.72, p<0.001) to say they would be more likely to use ItRunsInMyFamily.com. Similarly, increased odds were observed in women compared to men (OR: 1.45, p<0.001), black compared to whites (OR: 2.29, p<0.001), and Hispanics compared to whites (OR: 2.12, p<0.001) with regards to being more likely to use ItRunsInMyFamily.com.

† Univariate multiple logistic regressions across various outcomes adjusting for age group, gender, education, and ethnicity, weighted to the 2013 US Current Population Survey

* Significant at 0.05  
** Significant at 0.01  
*** Significant at 0.001

Interestingly, these differences change with the additional scenarios posed in the subsequent questions. For instance with age, there is a significant difference in likelihood of using ItRunsInMyFamily.com in the baseline scenario that changes to no difference in subsequent scenarios. Race also showed a reduction in difference, though blacks still remained statistically more likely to use ItRunsInMyFamily.com for all scenarios. Conversely, education showed an opposite trend between scenarios with college educated respondents going from slightly less likely in the baseline scenario to significantly more likely in scenarios related to family members, particularly when it would impact a family member’s health. See Table 2. There was little change in difference between scenarios in gender.

These results were further analyzed by fitting subject responses via GEE to estimate the odds of using ItRunsInMyFamily.com with regards to the baseline question and subsequent scenarios. Assuming compound symmetry, within subject correlation between the combination of the four scenarios presented was 0.59. With the baseline question as a reference, a doctor recommendation to use the website increases the likelihood of using the website, with an OR of 1.65 (95% CI: 1.57 - 1.74). A family member recommendation increases the odds of use to a slightly higher degree, with an OR of 1.79 (95% CI: 1.70 - 1.89). However, a family member recommendation because it could potentially help their treatment had the greatest effect on overall willingness to use the website, presenting an OR of 3.30 (95% CI: 3.08 - 3.53). While interactions between the scenario variable with each covariate were independently statistically significant (the result of large sample of complete responses), evaluation of mean plots over the scenarios indicate trends to be relatively parallel in most cases between levels of each of covariate, age, gender,
race, and education. However, the noteworthy trends across scenarios related to age and education level described above were further confirmed. See figure 2.

![Figure 2](image)

**Figure 2.** Generalized estimating equation trend plots for responses by age group and education

**Speaking to your doctor about FHx**

If respondents had FHx information on ItRunsInMyFamily.com, 92.3% of respondents would likely (40.0% extremely, 30.8% quite, 14.5% moderately, and 7.0% slightly) share the information with their doctor. Of note, 71% would be ‘extremely’ or ‘quite’ likely to share their FHx with their doctor. See Table 1. We assessed factors influencing a respondent sharing one’s FHx with his/her doctor. Individuals over the age of 60 (OR: 1.78, p<0.001), women (OR: 1.49, p<0.001), and individuals with a college education (undergraduate OR: 1.48, p<0.001; graduate OR: 1.52, p<0.001) are more likely to sharing FHx information with a doctor. Ethnicity was not found to be a significant factor. See Table 3.

As noted in the introduction, ItRunsInMyFamily.com will also identify and provide personalized recommendations to speak to a doctor about health risks that run in the family. As such, 90.3% of respondents would likely (26.0% extremely, 32.6% quite, 21.1% moderately, and 10.6% slightly) follow recommendations provided by ItRunsInMyFamily.com. Similarly, family members using ItRunsInMyFamily.com can influence one to speak to a doctor, in this case 91.1% of respondents would likely (25.2% extremely, 34.7% quite, 21.8% moderately, and 9.4% slightly) speak to a doctor if encouraged to by a family member. See Table 1. With the exception of Hispanic/Latinos now being significant (OR: 1.35, p<0.01), the same trends among covariates exist as the previous question. See Table 3.

Discussion

The scope of this study was to demonstrate interest and identify trends among potential users for ItRunsInMyFamily.com. We were encouraged by the relative interest and likelihood use of ItRunsInMyFamily.com by potential end users, particularly under specific scenarios. Our nationwide survey demonstrated that a majority of the U.S. population would likely use ItRunsInMyFamily.com to collect and record their FHx if given the opportunity. This is especially true if a doctor encourages its use, if a family member invites them to join, and most strongly if a family member with a health condition invites one to join because it could help that person’s care and/or treatment. This insight will guide development of ItRunsInMyFamily.com to emphasize clinician and family mediated invitations, to encourage sharing of health information, and to provide care recommendations. Importantly from a clinical perspective, we identified that users of ItRunsInMyFamily.com will be likely share FHx information with his/her clinician. Furthermore, many would follow recommendations provided by ItRunsInMyFamily.com or a family member to speak to a clinician about a particular health issue. These findings are fundamental to the clinical utility of ItRunsInMyFamily.com. Finally, we were encouraged by the relative comfort expressed by respondents for the proposed privacy and security approaches. While further research is warranted, particularly to better understand of individuals concerns, these results provide an early indication that privacy and security concerns may not significantly hinder the adoption of ItRunsInMyFamily.com among patients. Nevertheless, these results suggest that ItRunsInMyFamily.com is an acceptable way for patients to collect and use FHx to improve their care.

Notable trends

Some of the trends in the analysis were particularly interesting. Notably, we were surprised that younger individuals were initially less inclined to use ItRunsInMyFamily.com. Although this difference dissipated under various scenarios,
we had initially expected to see higher likelihood of usage among younger individuals because it is an online social networking tool. While this can be explored further, perhaps age and experience of older individuals with health care reinforces to them the need for resource like ItRunsInMyFamily.com. This assumption is reinforced by the observation that the over 60 age group would be statistically more likely to share their FHx information with their healthcare provider over all other age groups. It is important to note that the survey was conducted over the web, implying that respondents across all ages are biased to be more internet savvy. Therefore, it might not represent a true representation of the actual population, particularly among older individuals in this case. Nevertheless, the trend remains interesting and requires further exploration.

We were intrigued by the trends associated with race, particularly among African Americans respondents. Prior studies have shown that African Americans are less likely to participate in recording their FHx in writing. However, our results show an opposite trend with African Americans being more likely to use ItRunsInMyFamily.com and being more comfortable with ItRunsInMyFamily.com privacy and security approaches compared to the other ethnic groups. This may be due to the fact that, in general, African Americans have a very tight-knit extended family and extensive kinship networks on which they rely for informal social support. Other work has shown that the opinions of family members are valued by African Americans when making health care decisions and hence they may be likely to be comfortable with sharing information within the family. Also, previous research has shown that African Americans are more likely to 1) get health care information online, 2) use email to communicate with family members, and 3) use social networking systems on their phones as a way to be connected with family and friends. Therefore, despite the documented health disparities among African Americans, perhaps leveraging social networking technology to collect FHx is an ideal way to overcome health disparities related to FHx.

Future direction

Several efforts are currently underway to further explore various aspects of ItRunsInMyFamily.com prior to development of the social network. Currently, we are conducting a research project to explore ethical and legal issues related to sharing family health information with relatives using an online social network. While these issues have not escaped our consideration, the legal experts and ethicists working on this project do not believe there are any scenarios that would preclude ongoing development and research on the overall project. Rather, they affirm that thoughtfully developed policies and user privacy controls can mitigate many ethical and legal concerns. Indeed, it is within the scope of the project to define a legal and ethics framework which will guide ItRunsInMyFamily.com development and use. In a separate effort, we are identifying relevant health IT data models, standards and terminologies to be implemented within ItRunsInMyFamily.com to promote health information exchange with electronic health records, personal health records, and other health IT applications. By aligning with Meaningful Use requirements and participating in the nationwide health IT infrastructure, it will allow ItRunsInMyFamily.com users to import and export health information with various health IT applications. Continual user engagement is critical to the success of ItRunsInMyFamily.com, therefore we plan to incorporate proven strategies that promote user remuneration, influence, belonging, and significance to establish and maintain user engagement. Finally, once development of the site is complete, we will need to validate that the FHx information collected using an online social network is more complete and accurate than current FHx approaches, as hypothesized. To perform this validation, we plan to compare FHx collected through various approaches (e.g. genetic counselor, My Family Health Portrait, and ItRunsInMyFamily.com) to the health pedigrees available in the Utah Population Database (UPDB). The UPDB is a research database that provides a true gold standard of FHx information because it combines genealogical records, medical records, and other vital records of Utah citizens.

Conclusion

Results from this nationwide survey demonstrate that potential users are supportive of using an online social network to collect FHx. Results from this survey provide justification for ongoing efforts and will inform future research and development.

Abstract

Clinical Named Entity Recognition (NER) is a critical task for extracting important patient information from clinical text to support clinical and translational research. This study explored the neural word embeddings derived from a large unlabeled clinical corpus for clinical NER. We systematically compared two neural word embedding algorithms and three different strategies for deriving distributed word representations. Two neural word embeddings were derived from the unlabeled Multiparameter Intelligent Monitoring in Intensive Care (MIMIC) II corpus (403,871 notes). The results from both 2010 i2b2 and 2014 Semantic Evaluation (SemEval) data showed that the binarized word embedding features outperformed other strategies for deriving distributed word representations. The binarized embedding features improved the F1-score of the Conditional Random Fields based clinical NER system by 2.3% on i2b2 data and 2.4% on SemEval data. The combined feature from the binarized embeddings and the Brown clusters improved the F1-score of the clinical NER system by 2.9% on i2b2 data and 2.7% on SemEval data. Our study also showed that the distributed word embedding features derived from a large unlabeled corpus can be better than the widely used Brown clusters. Further analysis found that the neural word embeddings captured a wide range of semantic relations, which could be discretized into distributed word representations to benefit the clinical NER system. The low-cost distributed feature representation can be adapted to any other clinical natural language processing research.

Introduction

Clinical Named Entity Recognition (NER) is to identify boundaries and determine semantic classes (e.g., problems, treatments and lab tests) of clinical concept mentions in clinical text. Over the last few years, much attention has been focused on the clinical NER as it’s the critical step of unlocking important healthcare information from narrative clinical text. Much of the important patient information is locked in the narrative clinical text, which is not directly accessible for clinical applications that rely on structured data. Clinical NER systems identify clinical entities from narrative patient reports to support clinical and translational research. Various clinical NER modules have been developed in general clinical Natural Language Processing (NLP) systems (e.g., MedLEE1, MetaMap2, KnowledgeMap3 and cTAKES4). Most of the existing clinical NLP packages are rule-based systems that rely on comprehensive medical vocabularies. Recently, the clinical NLP community organized a series of open challenges with focus on identifying clinical entities from narrative clinical notes, including the 2009 i2b2 (the Center of Informatics for Integrating Biology and the Bedside) challenge5 on medication information extraction, the 2010 i2b2 challenge6 on recognizing medical problems, treatments, and tests entities, 2013 Share/CLEF challenge7 on disorder mention recognition and normalization, and the 2014 SemEval challenge8 on disorder mention recognition and normalization. Researchers developed rule-based systems, machine learning based systems as well as hybrid systems during the challenges. Currently, most of the state-of-the-art clinical NER systems are primarily based on the machine learning models.9,11

Supervised machine learning methods approach the NER as a sequence labeling problem, which aims to find the best label sequence (e.g., BIO format labels) for a given input sequence (individual words from clinical text). Researchers have applied various supervised machine learning algorithms, including Conditional Random Fields (CRFs)12, Maximum Entropy (ME), and Structural Support Vector Machines (SSVMs)13, to recognize clinical entities. Among the supervised machine learning algorithms, the CRFs is the most popular one for NER tasks as it’s intrinsically designed for sequence labeling problem by modeling the relationships between neighbor tokens. A number of top-ranked NER systems are primarily based on the CRFs. The supervised machine learning algorithms work well as researchers manually extract useful features and feature combinations through feature engineering. Orthographic information (e.g., capitalization of letters, prefix and suffix), syntactic information (e.g. POS tags), n-gram information, semantic information (e.g., UMLS concept unique identifier) and disclosure information (sections in the clinical notes) are often used as features in the typical NER systems. The combination of features, such as the...
word combined with POS tags, also prove to be useful. Subsequently, it was identified that the performance of the supervised machine learning algorithm could be further improved by “unsupervised features”, which are typically derived from unlabeled corpora using unsupervised machine learning methods such as Brown clustering. Conventionally, Brown clusters are converted into symbolic IDs to form the unsupervised feature representations. Brown clusters have been used successfully in a number of top-ranked clinical NER systems, such as the system from Bruijin in i2b2 2010 challenge and the system from Zhang et al. from the SemEval 2014 Challenge. The study from Tang et al. also found that unsupervised features could improve the identification of clinical entities that not covered by the training corpus. However, this one-hot word representation has limitations in that it only captures a single aspect relation of a word using sparse binary vectors. Researchers have explored the distributional semantics models to derive distributional word representations. Jonnalagadda et al. explored the random indexing model and found that the distributional word representations could enhance the performance of clinical concept extraction. Henriksson et al. further combined the distributional word representations with a large unlabeled in-domain corpus to generate additional features for de-identification of health records.

Recently, there has been an increasing interest in training word embeddings from large unlabeled corpora using neural networks. Word embeddings are typically represented as a dense real-valued low dimensional matrix \( M \) of size \( V \times D \), where \( V \) is the vocabulary size and \( D \) is the predefined embedding dimension. Each row of the matrix is associated with a word in the vocabulary and each column of the matrix represents a latent feature. The distributed word representations can be derived from the word embeddings. Different from the one-hot word representations such as the clustering feature from Brown clusters, the word embeddings have real-valued numbers to describe multi-aspect relations between words. Usually, the word embedding matrix is first initiated with random values and then tuned using neural networks induced by the neural language model. Bengio and Mikolov proposed different neural networks to train the word embeddings, where the probability of a word given by the previous word was estimated using the cross-entropy criterion. In 2010, Collobert et al. proposed a new neural language model to train word embeddings using ranking loss criteria with negative sampling. The experimental results showed that the ranking based word embeddings derived from the entire English Wikipedia corpus greatly helped the NER task in general English domain.

Previous studies have shown that the neural word embeddings could represent abundant semantic meanings and capture multi-aspect relations into a real-valued matrix. However, there is no conclusion on how to use the real-valued word embeddings in machine learning based clinical NER systems. In the biomedical literature domain, Tang et al. conducted a study to evaluate the different types of unsupervised word representations in biomedical NER task. They used the popular word2vec package to generate the word embeddings and showed that the word embedding features improved the F1-score of a baseline NER system by 0.49% (from 70.0% to 70.49%). The Brown cluster features improved the F1-score by 1.2% (from 70% to 71.2%), which was superior to the word embedding features. Tang’s study directly used the real values from the embedding matrix as features in a CRFs model without any discretization and the corpus size was relatively small (20,000 sentences from BioCreAtIvE II GM corpus and 22,402 sentences from JNLPBA corpus). Recently, research from Wang and Manning showed that conventional supervised machine learning models, such as the CRFs, have a preference for high dimension discrete feature space instead of low dimension real-valued feature space. Later in 2014, Guo et al. proposed two new strategies for deriving distributed feature representations from neural word embeddings trained from the entire English Wikipedia corpus. The experimental results showed that the proposed binarized embedding features (BinEmb – there are three possible values: “positive”, “negative” and “neutral” in BinEmb feature. However, we keep using this name to make it consistent with the previous research) and the distributed prototype features (ProtoEmb) were comparable to the Brown clusters.

However, until now there is no report of using neural word embeddings in the clinical domain. Compared with general English text, the clinical texts are much noisy with frequently occurred ungrammatical sentences, misspellings and abbreviations. It is not clear how the supervised machine learning based clinical NER systems could benefit from the neural word embeddings derived from the noisy clinical corpora. It’s also not clear which of the neural word embedding algorithms would be better for clinical NER tasks and how to utilize the word embeddings as features in machine learning based NER systems. In this study, we propose to 1) explore the power of a large unlabeled clinical corpus (403,871 notes) using deep neural networks (DNN); 2) compare the entropy-based neural word embedding algorithm and the ranking-based word embedding algorithm on the clinical NER task; 3) compare three different strategies for deriving distributed word representations from word embeddings in clinical NER tasks. To the best of our knowledge, this is the first study of training neural word embeddings from a large unlabeled clinical corpus and comparing different neural word embedding algorithms and strategies for deriving
distributed word representations. The most related study is that of Guo et al. in the general English domain, where they used only the word embedding algorithm implemented in word2vec. Another related study is by Tang et al. for NER in biomedical literature, where the study directly used the real values as feature weights without discretization, and the corpus size was relatively small.

Methods

Data sets

This study used the annotated corpora from the 2010 i2b2 challenge and the 2014 SemEval challenge. The i2b2 2010 corpus is annotated with three types of clinical entities including Problem, Test, and Treatment. All entities are composed of consecutive words. The SemEval corpus has only one type of entity – the disorder mention. However, the SemEval corpus contains disjoint entities – entities that are composed of more than one piece of text region. The following sentence illustrates an example: “The aortic root and ascending aorta are moderately dilated”. There are two disjoint entities: “aortic root ... dilated” and “ascending aorta ... dilated”. Table 1 shows the detailed information for the two labeled clinical corpora. In order to train the neural word embeddings and the Brown clusters, we utilized a 2.2 gigabytes of unlabeled clinical notes from the Multiparameter Intelligent Monitoring in Intensive Care (MIMIC) II corpus. The MIMIC II corpus is composed of 403,871 notes from four different note types. Table 1 shows the detailed information about the MIMIC II corpus. All the clinical notes were preprocessed using the same pipeline to separate sentences and tokens.

The Machine learning-based NER framework

To apply machine learning algorithms to the NER task, the annotated corpora are typically converted into “BIO” format, where “B” denotes “the beginning of a concept”, “I” denotes “inside of a concept”, and “O” denotes “outside of a concept”. E.g., a concept for the semantic category of medical problem can be represented using “B-problem” and “I-problem”. In this study, we developed a baseline clinical NER system based on the CRFs model. The baseline system covers the most common NER features including bag-of-word, Orthographic information (word patterns, prefixes and suffixes), syntactic information (POS - part of speech tags), n-gram of word and POS tags (unigrams, bigrams, and trigrams), disclosure information (sections and note types) and combination of words and POSa tags. We used the implementation of CRFs in the CRFsuite package (http://www.chokkan.org/software/crfsuite/). The model parameters were optimized using 5-fold cross validation on the training data, and the best parameters were used to predict the test data.

Integrate word embeddings with the NER framework

Neural word embedding algorithms

We explored two popular word embedding algorithms, including the word2vec from Mikolov and the ranking-based neural word embedding algorithm from Collobert. For word2vec, we used the implementation from “https://code.google.com/p/word2vec/” with the default settings (we used the CBOW model, which is faster and a little bit better than the skip-gram). As there is no out of shelf package for the ranking-based neural word embedding algorithm, we implemented the deep neural network according to the paper from Collobert using Java. We used the suggested parameters to train the neural network with a hidden layer size of 300, a fixed learning rate of 0.01, and an embedding dimension of 50. The standard stochastic gradient descent algorithm was used to optimize the neural network according to the ranking loss. The final word embeddings were represented as dense real-valued matrix. Each row in the embedding matrix associated with a word. Figure 1 shows examples of the word embeddings.
Figure 1. Examples of neural word embeddings

Neural word embedding as features

This study compared three different strategies of deriving distributed word representations from neural word embeddings. For each of the strategies, we derived corresponding distributed representations from the MIMIC II corpus and tested the effect of the derived features using the 2010 i2b2 data and the 2014 SemEval data.

1) Raw embedding feature (RawEmb)

The raw embedding feature is a straightforward way of using neural word embeddings. In this method, the real values from the embedding matrix were directly used as feature weights without any post processing. This method will generate the same number (equals to the dimension of the word embeddings) of feature representations for each word. Tang et al. used this strategy in their research\textsuperscript{14}. Figure 2 shows examples of the raw embedding features.

Figure 2. Examples of raw embedding features

2) Binarized embedding feature (BinEmb)

The binarized embedding feature was proposed by Guo et al.\textsuperscript{26} in 2014 for general English domain. The intuition of the binarized embedding feature is to discretize the real-valued matrix and omit the insignificant dimensions. Given a real-valued neural word embedding matrix $M_{F,D}$, the binarized embedding features can be derived by converting the real-valued embedding matrix to another discrete-valued matrix $M'_{F,D}$ with the discrete symbolic values in $[+,-,0]$. For the $j^{th}$ dimension (column) of the embedding matrix, we first calculate the positive mean $MEAN(j)^+$ and negative mean $MEAN(j)^-$ according to the following equations:

$$MEAN(j)^+ = \frac{1}{N_j^+} \sum_{i=0}^{N_j} M_{i,j}, \ M_{i,j} > 0$$

$$MEAN(j)^- = \frac{1}{N_j^-} \sum_{i=0}^{N_j} M_{i,j}, \ M_{i,j} < 0$$

where $N_j^+$ is the total number of rows with $j^{th}$ column $M_{i,j} >0$, and $N_j^-$ is the total number of rows with $j^{th}$ column $M_{i,j} <0$. Then the discrete-valued matrix $M'$ can be derived by the following projection:

$$M'_{i,j} = \begin{cases} +, & \text{if } M_{i,j} > MEAN(j)^+ \\ - , & \text{if } M_{i,j} < MEAN(j)^- \\ 0, & \text{otherwise} \end{cases}$$

Using the discrete-valued matrix $M'$, we can add the symbolic features according to the row vector associated with the word. Figure 3 shows examples of the binarized embedding features.

Figure 3. Examples of binarized embedding features

3) Distributed prototype feature (ProtoEmb)

The distributed prototype feature was also proposed by Guo et al.\textsuperscript{26} for the general English domain. Instead of using the embedding dimensions, the prototype feature method selects prototypical words as representative features for each label. The prototypical words will be assigned as features to the samples according to the distributed similarity
in the embedding matrix. Typically, the prototypical feature words are selected using the normalized pointwise mutual information (PMI) between the word and its labels (equation 4 and 5). For each word 'w' in the training/test, we calculate the cosine similarity between 'w' and all the selected prototypical words using the associated embedding vectors. If the cosine similarity is above the predefined threshold, the prototypical word will be assigned as a feature. Following the study by Guo\textsuperscript{26}, we tested different numbers of prototypical words and cutoff thresholds to select the best parameters. Finally, the top 40 prototypical words and a cutoff threshold of 0.5 were used to assign the prototypical words for the distributed prototype feature. Figure 4 shows the prototypical feature words selected for each label from i2b2 corpus and Figure 5 shows examples of assigned prototypical words.

\[ nPMI(label, word) = \frac{PMI(label, word)}{-\ln p(label) + p(word)} \]  

(4)

\[ PMI(label, word) = \ln \frac{p(label, word)}{p(label)p(word)} \]

**Experiments and Evaluation**

We ran two neural network embedding algorithms and Brown clustering algorithm on the unlabeled MIMIC II corpus to derive word embeddings and Brown clusters. For Brown clustering, we used the implementation from “https://github.com/percyliang/Brown-cluster/” and set number of clusters to 1,000. (We tested the different number of clusters from 50 to 2000 during the 2014 SemEval challenge. The cluster number 1,000 achieved the best performance) For each neural word embedding algorithm, we compared three different strategies for deriving word embedding features. Finally, we combined the best word embedding feature with the Brown clusters to examine how the clinical NER system could benefit from the large unlabeled clinical corpus. The official evaluation scripts provided by the i2b2 organizers and SemEval organizers were used to calculate the strict micro-averaged precision, recall, and F1-score. We report the performances of combining different types of unsupervised word representations on the 2010 i2b2 data and the 2014 SemEval data.

**Results**

Table 2 and Table 3 show the performances of the CRFs based NER system on the 2010 i2b2 data and the 2014 SemEval data respectively, when using different word representation features. The baseline system achieved F1-scores of 0.799 for the i2b2 data and 0.754 for the SemEval data. The baseline performance on SemEval data is lower than the performance on i2b2 data. The Brown cluster features improved the baseline system by 1.7% for the i2b2 data and 1.3% for the SemEval data. The binarized embedding features outperformed other embedding features and the Brown clusters, by improving the F1-score by 2.3% for the i2b2 data and 2.4% for the SemEval data. The combined feature from the binarized embedding features and the Brown clusters improved the F1-scores by 2.9% for i2b2 data and 2.7% for SemEval data, respectively.

All the unsupervised word representation features (including Brown clusters and word embeddings) improved the performances of the clinical NER systems. Further analysis found that the performance improvements are mainly from the recall. For example, the combined features from word embeddings and Brown clusters improved the recall by 5.3% for SemEval data and 5.1% for the i2b2 data, respectively. This is consistent with the previous research from the biomedical literature\(^\text{14}\). The performances of using the two word embeddings are comparable between the two challenge data sets. The ranking based word embedding algorithm from Collobert et al.\(^\text{23}\) performed slightly better than the word2vec.

Among the three strategies for using the neural word embeddings, the binarized embedding feature method achieved the best F1-score on both of the challenge data sets. Previous research\(^\text{14}\) from the biomedical literature showed that when using a moderate sized corpus (about 42,402 sentences), the Brown cluster feature is superior to the raw word embedding feature (1.2% vs 0.49% on JNLPBA corpus, and 2.1% vs 1.53% on BioCreAtIvE II GM corpus). Our study showed that the binarized embedding feature derived from a much larger corpus (403,871 notes) could be better than the Brown cluster feature (2.3% vs 1.7 for the i2b2 data and 2.4% vs 1.3% for the SemEval data). This could be explained on the basis of the study by Wang and Manning\(^\text{25}\), where the authors showed that the discrete high-dimension feature space works better in conventional machine learning models. Another possible reason may be that the marginal benefit of capturing the multi-aspect relations from a big unlabeled corpus is higher than the benefit from a moderate sized corpus. The distributed prototype feature was comparable to the binarized embedding feature. However, the distributed prototype feature benefitted the precision more than the binarized embedding feature.

To examine what the neural word embeddings captured in the real-valued matrix, we calculated the nearest neighbors using the embedding. Table 4 shows several nearest neighbor examples from the ranking based neural word embeddings. We can see that the neural word embeddings capture a wide range of semantic relations in both the general English domain (e.g., number, time unit, verb) and the clinical domain (e.g., gender, modifier, disorder, laterality, body location, medication). The embeddings also captured the semantic relations involving the clinical abbreviations (e.g., yr-year, l-left and r-right).

This research has limitations. The corpora used in this research are well preprocessed. However, the real world clinical notes are much noisy and heterogeneous. The comparison between neural word embeddings was conducted on a single conventional machine learning model (CRFs). The neural network model usually has high complexity, which may not fit well on the small corpus. We didn’t consider the hybrid systems and the existing knowledge bases (such as UMLS). We simplified the system to examine the promise of neural word embeddings – automatically learn knowledge from unlabeled clinical corpora. The best models in the i2b2 challenges (with the best F1-score of 0.852) and SemEval challenge (with the best F1-score of 0.813) show that the existing knowledge and more complex feature combinations could further improve the performance. It’s interesting to further examine the world embeddings in the deep neural network based classifiers and combine the existing knowledge bases into word embeddings.

Automatic feature learning from deep neural networks explore rich feature spaces, thus saving the clinical NLP researchers from time-consuming feature engineering. This study showed promising results of using deep neural networks to capture distributed word representations from a large unlabeled clinical corpus to improve the performance of clinical NER systems. Compared with labeled corpus, the unlabeled corpora are much easy to collect. The distributed word embedding features can be adapted to any other clinical NLP system. Moreover, this unsupervised knowledge is low cost - without any involvement of domain knowledge.

Conclusion

This paper studied the neural word embeddings for clinical NER. We systematically compared two popular neural word embedding algorithms and three strategies for deriving distributed word representation features from word embeddings. We also compared the distributed word representation feature with another widely used Brown cluster feature. Evaluation using two challenge datasets showed that the binarized embedding features derived from a large unlabeled corpus could remarkably benefit the clinical NER systems. The word embedding features can be easily adapted to any other clinical NLP research.

ABSTRACT

In scientific writing, positive credits and negative criticisms can often be seen in the text mentioning the cited papers, providing useful information about whether a study can be reproduced or not. In this study, we focus on citation sentiment analysis, which aims to determine the sentiment polarity that the citation context carries towards the cited paper. A citation sentiment corpus was annotated first on clinical trial papers. The effectiveness of n-gram and sentiment lexicon features, and problem-specified structure features for citation sentiment analysis were then examined using the annotated corpus. The combined features from the word n-grams, the sentiment lexicons and the structure information achieved the highest Micro F-score of 0.860 and Macro-F score of 0.719, indicating that it is feasible to use machine learning methods for citation sentiment analysis in biomedical publications. A comprehensive comparison between citation sentiment analysis of clinical trial papers and other general domains were conducted, which additionally highlights the unique challenges within this domain.

INTRODUCTION

Sentiment analysis aims to determine the sentiment polarity conveyed through a segment of text with respect to a specific entity (opinion target)\textsuperscript{1,2}. This entity can be individuals, objects, or topics. With the expanding use of social media, such as blogs and social networks starting from the year 2000, sentiment analysis has attracted increasing attention. Massive opinion data conveying personal sentiments are available online, which were very valuable for business intelligence applications, such as the product search engines\textsuperscript{3}. These intelligent systems are supported by sentiment analysis methods that automatically identify the sentiments from product and service reviews\textsuperscript{3,4}. A quick perusal of existing work shows that most of the state-of-the-art studies approach sentiment analysis as a classification problem. Depending on the granularity of the text regions, sentiment analysis can be conducted at three levels, i.e., document-level\textsuperscript{5}, sentence-level\textsuperscript{6}, and aspect-level\textsuperscript{7}. Typically, the sentiment corpora are composed of reviews, e.g. movie reviews\textsuperscript{5} and product reviews\textsuperscript{6}, news articles\textsuperscript{8,7} and tweets\textsuperscript{8,9}. Researchers have applied different strategies for sentiment analysis, including keyword spotting, lexical affinity, statistical methods, and concept-level techniques\textsuperscript{10}. In the biomedical domain, sentiment analysis has already been used for detection of adverse drug reactions\textsuperscript{11}, assessment of suicide risk\textsuperscript{12}, evaluation of doctor service\textsuperscript{13}, hospital quality survey\textsuperscript{14}, and public health policy making\textsuperscript{15}.

Citation sentiment analysis is an application of sentiment analysis in citation content analysis\textsuperscript{16}, which aims to determine the sentiment polarity that the citation context carries towards the cited paper. In citation sentiment analysis, the opinion target is the cited paper, and the categories of sentiment polarity could be either positive, negative or neutral. Citation content analysis studies are useful for investigating the numerical, literal, and sociocultural\textsuperscript{17} aspects of citations, focusing on the classification of citation functions\textsuperscript{18}, roles\textsuperscript{19}, and the academic influence measures\textsuperscript{20}. Some of the categories in these studies are also related to citation sentiments, e.g., ‘Contrast/Conflict’ and ‘Similarity/Consistency’ in the study by Agarwal et al\textsuperscript{19}. Of late, citation sentiments analysis has emerged as a novel research topic in this area. Athar and Teufel\textsuperscript{21,22} proposed to use citation sentiment analysis to identify whether a particular act of citing was done with positive or negative intentions in computational linguistic publications.

One potential application of citation sentiment analysis is to improve bibliometric measures. In traditional bibliometrics, the impact of a research article is usually measured by citation frequency. Diverse citation counting-based measures, like the Hirsch index\textsuperscript{23} and the g-index\textsuperscript{24}, offer a quantitative proxy to determine the impact. However, all citations are treated equally in these measures, without making any distinctions between the essential function of a citation, i.e., whether the cited work is credited or criticized. Citation sentiment analysis could therefore be used to improve the existing bibliometrics measures by introducing different weights, based on the
specific sentiments of the citations. Moreover, it can provide evidence for scientific authoring support\textsuperscript{25} and citation bias analysis\textsuperscript{26,27}.

Another potential application of citation sentiment analysis in the biomedical domain is to detect non-reproducible studies. Over the last few years, the reproducibility of existing research has become an important issue in the biomedical domain. In a recent research paper, the researchers from Amgen Inc. found that 47 of 53 ‘landmark’ oncology publications could not be replicated \textsuperscript{28}. Moreover, increasing numbers of research articles are being retracted from prestigious journals due to the reproducibility issue. Therefore, it is important to detect non-reproducible studies as soon as possible, to avoid wasting resources, e.g., expensive drug-discovery projects that attempt to confirm non-reproducible results. Here we propose that the sentiment polarity conveyed in the citation context could be a useful clue denoting the reproducibility of the cited paper. For example,

\textit{I. Thus, inhibition of SATB1 expression does not appear to alter the aggressive phenotype of breast cancer cell lines in vitro, in contrast to the results reported by Han et al. [1].}

In the above example I, a negative opinion is expressed towards the cited paper (reference id: 1), implying that the citing work could not reproduce the cited work. The reproducibility of a study could thus be evaluated by aggregating the sentiments dispersed in the publications citing it as a reference. Thus, citation sentiment analysis comprises the preliminary step towards reproducibility evaluation. However, there are limited studies about citation sentiment analysis in the biomedical domain. The most related study is from Yu\textsuperscript{25}, where the author analyzed the needs of citation sentiment analysis and suggested that it should consider the sentiment of both specific claims and the citations.

To address the critical problem of evaluation of research reproducibility, this study proposed to identify citation sentiment in clinical trial papers using machine learning methods. A citation-level annotated sentiment analysis corpus composed of 285 clinical trial related publications was first constructed. Based on the corpus, we developed a machine learning based classifier and systematically compared different features and feature combinations. The experimental results show that it is feasible to use machine learning classifiers to identify citation sentiments from biomedical publications. One thing to be noted is that both the annotation and detection of citation sentiment are context-enhanced. To the best of our knowledge, this is one of the first studies that addresses automated citation sentiment analysis in the biomedical domain.

METHODS

This study attempts to classify the sentiment polarity of a citation in clinical trial papers, i.e., the sentiment polarity relation between the citing and the cited paper, based on the sentiment analysis of the content of citation context. We first annotated a citation sentiment analysis corpus, which contains discussion sections extracted from 285 clinical trial papers. The citation sentiment polarity was annotated at the citation-level by following an annotation guideline. A simple rule-based method was used to extract the citation context, which is a set of on-topic sentences. The citation sentiment polarity was then classified using machine learning methods incorporating features extracted from the citation context. The performance of citation sentiment analysis was evaluated using the 10-fold cross-validation method.

Data Set Annotation

Data Set Selection The data we used in this study are derived from clinical trial papers. Some clinical trials are ‘self-correcting’ studies, which are founded on the replication of the earlier trials. The clinical trial paper contains the opinionated citations we wanted and satisfied the purpose of our concern on the reproducibility of biomedical research. We used the query “clinical trial[Title] AND ("research and review articles"[filter] AND "open access"[filter] AND "2004/06/01"[PubDate] : "2014/05/31"[PubDate])” to search the Pubmed Central (PMC)\textsuperscript{*}. Then we downloaded all the papers in the search results from the PMC archive using OAI-PMH service\textsuperscript{†}. We randomly selected 285 papers for corpus construction. The clinical trial paper in the biomedical domain has a purely descriptive style and a very standardized structure known as Introduction, Methods, Results, and Discussion (IMRAD). Most of the opinionated citations were found in the discussion section. Therefore, we only extracted the content of the discussion section. Multiple-references citation, e.g. ‘[1], [3]’ or ‘[3-10]’, was treated as one citation, since they share same citation sentiment polarity. Based on the above criteria, we obtained 4182 citations.

\textsuperscript{*} http://www.ncbi.nlm.nih.gov/pmc/
\textsuperscript{†} http://www.ncbi.nlm.nih.gov/pmc/tools/oai/
**Annotation Schema** In previous work\textsuperscript{21, 22}, each sentence which has a citation was treated as the citation context, and the sentiment was labeled at the sentence level. In our study, we annotated each citation based on its context. The citation level annotation is applied for the following reasons. First, in science papers, the context scope of a citation varies widely, from a clause to several sentences, even a paragraph. Second, there are some sentences which have more than one citation and have different sentiment polarities.

Based on our observation of the problem, we developed a simple and practical annotation scheme. We illustrate it as a decision tree, as shown in Figure 1 below. There are no instructions about the use of cue phrases. This study does not consider the correctness or incorrectness of the claims, ideas, results and conclusions presented in the citing or cited paper. The opinion target is the cited paper, not a scientific claim. For example, both citations in “Xxx et al. \textsuperscript{[3]} concluded that ..., which did not agree with Yyy et al. \textsuperscript{[7]}.” are labeled as neutral.

**Annotation Process** For the annotation task, three annotators were employed. According to the scheme discussed earlier, all citations were annotated by the two primary annotators. One of the annotators was a physician and served as the domain expert. The third annotator was involved when the two primary annotators have differing annotations for the same citation.

![Decision Tree](https://example.com/decision_tree.png)

**Figure 1. Simple annotation scheme designed as a decision tree**

**Citation Context Extraction**

Citation context is defined as the textual statement that contains the citation. It is a set of on-topic (describing the target citation) sentences surrounding the citation. In our study, we hypothesized that citation context will provide relevant and related information which will help identify the citation sentiment. Most of the citations’ sentiment can be determined by the sentence which contains the citation itself. However, some of them need sentential context. A simple rule-based method was developed to extract the context content for each citation. First, for each citation (target citation), we extracted the whole sentence that contains it. Then, if the next sentence did not contain other citation(s), and there was a contrastive discourse relation between the two sentences, the next sentence was also added to the citation context. To determine the contrastive relation, a small set of cue-phrase-based patterns were used, including ‘however (.)...’, ‘conversely, ...’, etc. The citation context extraction partially solves the problem of complex discourse structure, which may have expression of true opinion.

**Citation Sentiment Polarity Classification**

**Features**

Considering the characteristics of citation sentiment analysis, we systematically extracted the following features, including word n-grams, sentiment lexicons and problem-specified structure features.
(1) Word n-grams

All unigrams, bigrams and trigrams in the citation context were extracted as features. Since negation words always affect the polarity, they have to be taken into consideration in sentiment analysis. The total count of negation phrases found within the citation context was therefore extracted as features. Furthermore, artificial words like 'NOT_w' were extracted if the word ‘w’ was in the scope of negation. In this study, the negation scope was set as 2-words to the right of negations.

(2) Sentiment lexicons

Researchers use sentiment words to express opinions, which could be used as clues for citation sentiment analysis. We manually created a biomedical research paper specific sentiment lexicon. The lexicon includes 53 positive and 46 negative phrases. They were extracted from the corpus we built. Most of them are high frequent words found in biomedical literature. The presence and absence of a sentiment word were also extracted as features in addition to their sentiment polarities. We also assigned opposite polarity if the sentiment word was detected within the scope of a negation word.

(3) Structure features

Based on the observation of the examples, we found that the sentiment of citation was constrained by the intra- and inter-sentence features, including contrast discourse relation, sentiment words, negation words, comparative relation, related position and direction information of citing work, target, and other non-target cited work. We extracted and combined all these features in an order to generate structure features, which have better representation power by retaining intra- and inter-sequential relations. In scientific writing, researchers usually use a number of particular ways to express their sentiment regarding a citation, such as comparative expression and complex discourses. Thus, we designed a feature extraction pipeline to capture those complex structures. As shown in Table 1, the feature extraction pipeline composed of two steps: 1) Extract and tag all of the citing work tokens, comparative tokens, negation words, sentiment tokens, contrastive discourse cue words in the citation context. This is rule-based processing. We built a series of cue-phrase-based patterns to recognize concept entities like citing works, negation words, comparative expressions, and contrast discourse relations; 2) Generate the unigram, bigram and trigram of recognized concepts as features. If there is a contrast discourse relation in the citation context, we also generated the direction feature. It represented the position and direction information of citing, cited works and the contrast cues, as shown in the last row of Table 1.

Table 1. An illustration of the structure features extraction.

</tbody>
</table>
Machine Learning Algorithms

Before the feature extraction, the reference markers in the sentence, such as ‘[3]’, ‘[8, 9]’, and ‘[2, 6-10]’ etc., were identified. A citation context may contain several citations. Consequently, we replaced the text of target citation and other citations with the tokens ‘[TC]’ and ‘[OC]’, respectively. Then, we extracted the features from the citation context. Each citation context was represented as a feature vector. In this study, Support Vector Machines (SVMs) was employed for its known performance on previous sentiment analysis tasks. More specifically, the implementation of LIBLINEAR was used in our study. Parameters for SVM classifiers were optimized based on training set.

Evaluation

This study adopted the standard evaluation metrics. We reported the accuracy (Acc.), Micro- and Macro- F across all the categories. As the corpus is imbalanced, we further reported the precision (P), recall (R) and F-measure (F) for each category. In the experiments, 10-fold cross validation was performed. All the performances given below are the average of 10 folds. We report the results with different combinations of features.

RESULTS

Table 2 shows the descriptive statistics of the corpus. The corpus contains 702 positive, 308 negative and 3172 neutral samples. The KAPPA value among the annotations from the two primary annotators’ was 0.504. It is a moderate agreement level.

Table 3 shows the results of the citation sentiment analysis on the corpus we annotated. Different combinations of features were tested. Default parameters of LIBLINEAR package were used. We treat the results achieved using word n-gram features as the baseline. By adding sentiment lexicon features or structure features, the recall as well as the overall performance of both negative and positive class increased significantly. With a combination of all the features, we reached the best overall performance (accuracy of 0.870) and the highest F for each class, with 0.511 for “negative”, 0.924 for “neutral”, and “0.723” for “positive” respectively.

Feature sets: (1) Word n-grams; (2) Sentiment lexicons; (3) Structure features.
DISCUSSION

We conducted a study on identifying the sentiment polarity from the citation context in clinical trial papers using machine learning methods. The combined features from the word n-grams, the sentiment lexicons and the structure information achieved the highest Micro-F score of 0.860 and Macro-F score of 0.719, validating the promise of using automated machine learning methods to analyze the sentimental polarities in citation context from biomedical literature.

In this study, we constructed a citation analysis corpus from 285 randomly selected clinical trial related research articles. To the best of our knowledge, this is the first citation sentiment analysis corpus in the biomedical domain. The annotators had a moderate inter-annotator agreement with a Kappa of 0.5040, suggesting that citation sentiment identification is challenging even for domain experts. We also found that biomedical researchers expressed their sentiments in many different ways, which cannot be identified by simply using the sentiment lexicons. Sometimes, the annotators had to link distant citation context to figure out the sentiment polarity, which made it more difficult to automatically identify the sentiment using machine learning methods.

Compared to general sentiment analysis study on product reviews, news articles, and Twitter, citation sentiment analysis on biomedical literature presented several unique challenges.

(1) Most of the citations were neutral with respect to sentiment. The purpose of citing was to gain information, such as background, methods and data information from the cited work. Authors typically used objective words in the citation context. As a result, the corpus we constructed for citation sentiment analysis is imbalanced, as shown in Table 2. An example sentence is shown below:

II. CU has been widely studied throughout literature for its anti-inflammatory [13, 14], anti-oxidant [15], antibacterial [16] and wound healing [17], properties.

(2) Sentiment polarity was often expressed as a comparative sentence. Typically, the authors used comparative claims to express opinions, either refuting or confirming a previous work, as comparative claims clearly describe similarity or difference relation between the citing and the cited work. The negativity or positivity was implied by the comparison with the authors’ work. An example is noted below:

III. Compared with previous studies using intratumoral or intravenous infusion of rAd-p53 [6], this study achieved higher overall clinical response rates with intra-arterial administration.

(3) Scientists are reluctant to be critical when they cannot reproduce previous results. In some cases, the express of citation sentiment is very implicit without any explicit linguistic cues, such as negative words. Please see below for an example.

IV. It has been reported that the inclusion of micronutrients can decrease the number of acute respiratory infections [36]. In the present study, no differences were found in respiratory tract infections among treatment groups.

(4) The context scope of a citation varied widely, from a single clause to multiple sentences. Meanwhile, adversative transition words were used extensively to connect these clause or sentences. The citation sentiment was constrained and implied by these intra- and inter-sentence discourse relation. A multiple sentences example is provided below.

V. Previous reports by Ulrichs et al. have shown that IFN-g producing cells against ESAT6 in tuberculosis patients increase post-tuberculosis therapy [18]. However, we were unable to demonstrate any difference in ESAT6-induced IFN-γ responses between patients prior to and post-treatment. This is in concordance with a recent report by Coussens et al. [14] that did not show any change in ESAT-6 induced IFN-g in patients’ post-antituberculous therapy.

In conclusion, imbalanced data, comparative expression, implicit sentiment and complex discourse structure made the citation sentiment analysis more challenging in the biomedical domain.

The clinical trial related biomedical literature is usually about biomedical findings. The biomedical researchers express their sentiments indicating whether his work confirms, supports, or agrees with the cited paper. The literature in other domains, such as the computer science, is more about theoretical models, algorithms and application systems. Therefore, the scientists used different ways to express sentiments in different domains. For
examples, “agree with” and “confirm” were always used within a positive citation context in the biomedical domain. However, they were uncommon in the literature of computer science.

Although the overall performance on the three sentiment categories is promising, the performance for the negative category still needs to be improved. We conducted an error analysis for the negative category and found that the low performance was caused by the implicit sentiment expression and complex discourse structures. Normally, the authors tried their best to avoid giving explicit personal effect especially negative credit to the cited paper. Further, the intentions of the authors were not sometimes available to the content analyst. For example, in the sentence “We did not observe any reductions in mortality, as did Ferrer and colleagues [14].”, more subjective interpretation to assign citations to the defined sentiment categories is required. Textual entailment techniques may be required to determine whether the mentioned statement contradicts the claim of the cited paper or not. In our study, for simplicity, we only proposed a rule based citation context extraction method. The on-topic sentence could potentially be missed if the cue words are out the scope of the two continuous sentences. Furthermore, other discourse relations related to sentiment analysis were not taken into account.

The method we used is not proposed for learning from imbalanced data. Some state-of-the-art methods for imbalanced learning may improve the performance of minority classes. That’s one of the aims of our future work. For minority classes, it is hard to collect enough samples for training. However, massive citations can be obtained easily. Semi-supervised methods could be a potential way to handle the imbalanced data problem for citation sentiment analysis. Another limitation of this study is that data were collected from clinical trial papers only; therefore more optimizations would be required when we extend the work to all biomedical papers.

CONCLUSION

In this study, we manually annotated a citation sentiment corpus for clinical trial papers and developed a machine learning approach to determine sentiment polarity of biomedical citations. We conducted experiments to examine the effectiveness of the common features (i.e., word n-gram and sentiment lexicons) and structure features in classifying citation sentiment. Our results and analysis indicate that it is feasible to determine biomedical citation sentiment using machine learning approaches, although challenges still exist. In the future, we will enhance our approach by employing methods for imbalanced data and discourse relations analysis techniques that could extract more informative context features.

Abstract

Targeted cancer drugs are often associated with unexpectedly high cardiovascular (CV) adverse events. Systematic approaches to studying CV events associated with targeted anticancer drugs have high potential for elucidating the complex pathways underlying targeted anti-cancer drugs. In this study, we built tcTKB, a comprehensive CV toxicity knowledge base for targeted cancer drugs, by extracting drug-CV pairs from five large-scale and complementary data sources. The data sources include FDA drug labels (44,979 labels), the FDA Adverse Event Reporting System (FAERS) (4,285,097 records), the Canada Vigilance Adverse Reaction Online Database (CVAROD) (1,107,752 records), published biomedical literature (21,354,075 records), and published full-text articles from the Journal of Oncology (JCO) (13,855 articles). tcTKB contains 14,351 drug-CV pairs for 45 targeted anticancer drugs and 1,842 CV events. We demonstrate that CV events positively correlate with drug target genes and drug metabolism genes, demonstrating that tcTKB in combination with other data resources, could facilitate our understanding of targeted anticancer drugs and their associated CV toxicities.

Introduction

Treatment outcomes in cancer patients have dramatically improved since the introduction of targeted drugs. However, targeted drugs are often associated with unexpectedly high cardiovascular (CV) toxicities in cancer patients [1-2]. The mechanisms by which targeted drugs exert their toxic effects on heart and vasculature in cancer patients are not well-understood [3-4]. To ensure safe personalized cancer treatment, research efforts are needed to understand CV toxicities associated with targeted drugs. Systematic and integrated approaches to studying CV events associated with targeted drugs have high potential for elucidating the complex pathways underlying anti-cancer drugs, identifying the on- and off-targets of undesirable CV events, and predicting unknown CV toxicities [5-7]. However, systematic study of targeted drug-induced CV toxicities has been hampered by the lack of a comprehensive and machine-understandable knowledge base of drug-CV associations. The relevant knowledge is instead buried throughout multiple disparate and complementary information sources in varying formats. It was recently demonstrated that 39% of serious events associated with targeted cancer drugs were not reported in clinical trials and 49% were not described in FDA drug labels [8]. Therefore, in order to build a comprehensive knowledge base of CV toxicities associated with targeted drugs, it is important to extract knowledge from multiple complementary data sources.

Recently, we extracted targeted anticancer drug-associated CV events from the U.S FDA Adverse Event Reporting System (FAERS) (4,285,097 records) [9]. We also developed text classification, relationship extraction, signaling filtering, and signal prioritization algorithms to extract targeted anticancer drugs associated side effects, including CV events from 13,855 full-text articles and embedded tables from the Journal of Oncology (JCO) published between 1983 and 2013 [10-11]. In this study, we built tcTKB (the CardioToxicity Knowledge Base for Targeted Cancer Drugs) by combining drug-CV pairs extracted from FAERS and JCO articles with pairs from another three large-scale and publicly available datasets: U.S. Food and Drug Administration (FDA) drug labels (44,979 drug labels), the Canada Vigilance Adverse Reaction Online Database (CVAROD) (1,107,752 records), and the vast corpus of published biomedical literature (21,354,075 MEDLINE records).

Drug toxicity knowledge contained in these five data sources is largely complementary. FDA drug labels contain known adverse events associated with commercial drugs, which are mainly gleaned from controlled clinical trials. Drug-CV pairs from FDA drug labels are highly accurate (high precision), however the recall may be limited since
they are mainly obtained from pre-marketing clinical trials for well-controlled patients (i.e. patients with less co-morbidities or younger patients). The two post-marketing surveillance systems (FAERS and CVAROD) contain both voluntary and mandatory reports of suspected drug adverse events from health-care professionals, consumers, and pharmaceutical companies for drugs used in less controlled 'real-world' patient populations. FAERS is the main spontaneous reporting system overseen by the U.S. FDA. Mining drug-side effect (drug-SE) relationships from FAERS is a highly active research area. Data mining algorithms such as disproportionality analysis, correlation analysis, and multivariate regression have been developed to detect adverse drug signals from FAERS [12-14]. Recently, we developed signaling extraction, prioritization, filtering algorithms and extracted a total of 11,173 drugCV pairs, representing 39 targeted cancer drugs and 1095 CVs, from FAERS [9]. In this study, we will extract drug-CV pairs from CVAROD, the main spontaneous reporting system overseen by Health Canada. CVAROD contains more than one million patient records, however, research effort in mining drug safety signals from CVAROD is significantly less compared to efforts in mining FAERS. Drug-CV pairs extracted from these two post-marketing surveillance systems are comprised of known true positives (those included in FDA drug labels), unknown true positives, and false positives. The main challenge is to differentiate between unknown true positives and false positives.

JCO is the official journal of the American Society of Clinical Oncology and the leading journal in oncology. JCO articles not only include pivotal clinical trials that have led to drug approval, but also trials that are still in investigational stages and even failed trials. In one of our recently studies, we downloaded a total of 13,855 full-text JCO articles published between 1983 and 2013. We combined automatic table classification and relationship extraction approaches to extract anticancer drug-associated side effects from a total of 31,255 tables embedded in these JCO articles [10]. We also developed an integrated system combining text classification, relationship extraction, signal filtering, and signal prioritization algorithms to extract targeted anticancer drug-associated side effects from the full-text part of JCO articles [11]. We demonstrated in our previous studies and in this study that full-text oncological articles contains much drug-associated side effects including CV events that are not captured in FDA drug labels, MEDLINE abstracts, or post-market drug safety surveillance systems.

Currently, more than 22 million biomedical records are publicly available on MEDLINE, making it a rich source of CV toxicity information for drugs at all clinical stages, including drugs in pre-marketing clinical trials, post-marketing clinical case reports and clinical trials. The major challenge in extracting drug-CV pairs from this rich source is that it is buried in free-text format. We recently develop approaches to extract drug-SE pairs from MEDLINE [15-16]. In this study, we will apply these approaches to extract target anticancer drug-associated CV events from MEDLINE abstracts. In this study, we show that as much as 96% and 67% targeted anticancer drug-associated CV pairs extracted from MEDLINE are not included in FDA drug labels and FAERS, respectively, demonstrating the need of building tcTKB from multiple complementary data resources. To the best of our knowledge, this is the first research effort in building a comprehensive CV toxicity knowledge base for targeted drugs from multiple complementary data sources. We demonstrated that this unique knowledge base tcTKB, in combination with other data resources such as drug target databases or drug pharmacogenetics and genomics databases, can facilitate our deeper understanding of the molecular mechanisms underlying the unexpectedly high incidence of CV toxicities associated with many targeted anticancer drugs.

Data and methods

The data resources and methods that were used to construct tcTKB is depicted in Figure 1 and described later.

Data

The four data sources for extracting targeted anticancer drug-associated CV pairs are summarized in Table 1 and described in the sections that follow.

FDA drug labels We downloaded a total of 44,979 drug labels, including 21,610 human prescription labels and 23,369 human OTC labels from DailyMed. DailyMed is maintained by the National Library of Medicine (NLM)
and provides high quality FDA package inserts information about marketed drugs. The majority of drug side effect information captured on FDA drug labels is obtained from clinical trials, while some is obtained from post-marketing surveillance. We used the publicly available information retrieval library Lucene\(^2\) to create a local FDA drug label search engine with indices created on drugs, section headers such as “Indications,” “Contraindications,” and “Adverse Reactions;” and sentences. Each sentence was associated with a drug and a subsection header name.

**The FDA Adverse Event Reporting System (FAERS)** FAERS is the prominent post-marketing drug safety surveillance system maintained by the U.S. FDA. In our recent study, we downloaded a total of 4,285,097 records from FAERS for the time period of 2004 to 2012\(^3\). We extracted a total of 11,173 drug-CV pairs, representing 39 targeted cancer drugs and 1095 CVs, from FAERS [9].

**The Canada Vigilance Adverse Reaction Online Database (CVAROD)** CVAROD is the main post-marketing drug safety surveillance system in Canada. A total of 1,107,752 patient records were downloaded\(^4\). File “reactions.txt” contains the reported adverse events. File “drug_product Ingredients.txt” contains drug information. Similar to pairs extracted from FAERS, pairs in CVAROD could contain spurious pairs as well as unknown true positives.

**JCO full text articles** In our previous study, we downloaded a total of 13,855 JCO full text JCO articles published from 1983 through 2013 and extracted anticancer drug-SE pairs from both the text and the tables in the articles [10-11]. We extracted a total of 3,515 drug-CV pairs, representing 45 targeted anticancer drugs and 449 CV events.

**MEDLINE data and local MEDLINE search engine** We downloaded a total of 21,354,075 MEDLINE records (119,085,682 sentences) published between 1965 and 2012 from NLM (http://nlm.nih.gov/Download/index.shtml). Each sentence was syntactically parsed with Stanford Parser [16] using the Amazon Cloud computing service (a total of 3,500 instance-hours with High-CPU Extra Large Instance were used). We created a local MEDLINE search engine

with indices created on sentences, their corresponding parse trees, and abstracts.

**Lexicon of targeted cancer drugs** The 45 targeted cancer drugs was obtained from the National Cancer Institute\(^5\).

**Lexicon of cardiovascular event (CV) terms** We built a lexicon of CV terms based on MedDRA, a medical terminology widely used for classifying adverse events associated with drugs and other medical products\(^6\). The adverse events captured on FDA drug labels, FAERS, and CVAROD are coded with MedDRA terms. We created a lexicon of CV terms by finding all leaf nodes with the ancestor “vascular disorders” or “cardiac disorders.” This lexicon consisted of a total of 1,712 CV terms, including 1,269 vascular disorders and 527 cardiac disorders. In order to capture all the term variations in MEDLINE, we expanded the CV lexicon by including the synonyms of the terms in the lexicon. The term-synonym mappings were derived from UMLS Semantic Network [17]. After expansion, the CV lexicon consisted of 27,547 terms.

**Methods**

**Extract drug-CV pairs from FDA drug labels** We used each of the 45 * 1,712 drug-CV combinations (45 targeted drugs and 1,712 CV terms) as search queries to the local FDA drug label search engine. Drug-CV pairs that appeared in sentences with the header “Adverse Reactions” were retrieved. We extracted a total of 259 drug-CV pairs from FDA drug labels, representing 15 targeted cancer drugs and 75 CV events. These pairs are of high quality and represent known cardiovascular events associated with targeted cancer drugs derived from both pre-marketing clinical trials (major) and post-marketing surveillance (minor).

**Extract drug-CV pairs from FAERS** Drug-CV pair extraction from FAERS was done in our previous study [9]. After file linking, drug entity recognition and mapping, and CV entity recognition, we obtained a total of 11,173 drug-CV pairs, representing 39 (out of 45) targeted drugs and 1,095 (out of 1,712) CV events.

**Extract drug-CV pairs from JCO articles** Drug-CV pair extractions from JCO articles (including both full-text and embedded tables) were done in our previous study [10-11]. We extracted a total of 3,515 drug-CV pairs, representing 45 (out of 45) targeted anticancer drugs and 449 (out of 1,712) CV events.

**Extract and prioritize drug-CV pairs from CVAROD** We extracted drug-CV pairs from CVAROD by linking three downloaded files: (1) Report_Drug.txt, which provides report drug identifiers and adverse reaction report numbers; (2) Drug_Product_Ingredient, which provides drug identifiers and active ingredient names; and (3) Reactions.txt, which provides adverse reaction report numbers and adverse reaction terms. We first linked the file “Drug_Product_Ingredient” with file “Reactions.txt” using the identifiers specified in “Report_Drug.txt”. We then extracted drug-CV pairs from the linked file. Unlike drug strings in FAERS, drugs in CVAROD were already mapped to their active ingredients, therefore no additional concept recognition and mappings were necessary. We filtered the drugs with the lexicon of 45 targeted cancer drugs. The same named entity recognition for CV terms as was completed for FAERS [9] was also performed for the data collection from CVAROD. In total, we obtained 1,160 drug-CV pairs, representing 31 targeted cancer drugs and 300 CVs.

While drug-CV pairs extracted from FDA drug labels are known true positives, pairs extracted from CVAROD contain known true positives, unknown true positives, and true negatives. In order to prioritize drug-CV pairs extracted from CVAROD, we implemented and compared six ranking algorithms in prioritizing true signals, including ranking by pairs’ frequency counts (FREQ) in FAERS, and five commonly used Disproportionality Analysis (DPA) statistical signal detection approaches: relative reporting ratio (RRR), proportional reporting ratio (PRR), reporting odds ratio (ROR), phi coefficient (PhiCorr), and information component (IC). The five DPAs are currently the most widely used approaches for automated signal detection in FAERS [11]. All these DPA methods are based on frequency analysis of 2x2 contingency tables to estimate statistical association between drugs and SEs and it intends to quantify the degree to which a drug-SE pair co-occurs disproportionally in the database. These five DPA methods differ by the statistical adjustments they apply to account for low counts.

\(^{5}\)http://www.cancer.gov/cancertopics/factsheet/Therapy/targeted

\(^{6}\)http://www.meddrampsso.com/
In order to compare different ranking methods, we used 11-point interpolated average precision, a commonly used measure in evaluating information retrieval results [18]. For each ranked list, the interpolated precision was measured at the 11 recall levels of 0.0, 0.1, 0.2, ..., 1.0. At each recall level, we calculated the arithmetic mean of the interpolated precision. A composite precision-recall curve showing 11 points was then graphed. In order to compare these six ranking approaches in prioritizing true signals, we used the 259 drug-CV pairs extracted from FDA drug labels as the evaluation dataset, which consisted of known true positives. If a ranking algorithm ranks known true positives highly, we can reason that it also ranks many unknown true positives highly. Note: this evaluation dataset was not used to calculate the true precisions and recalls, but to compare the six ranking approaches in prioritizing true signals.

**Extraction and manual curation of drug-CV pair from MEDLINE** We used each of the 45 * 27,547 drug-CV combinations for the 45 targeted cancer drugs and 27,547 CV terms as search queries to the local MEDLINE search engine. Sentences, their associated parse trees, and abstracts that contained each pair were retrieved. Instead of simply retrieving a pairs co-occurrence counts at both sentence- and abstract-level from the search engine, we added the extra restriction that both drug and CV terms must be noun phrases in retrieved parse trees. This additional restriction was put in place to prevent the extraction of partial drug-CV pairs from sentences. For example, a CV term appeared as a substring in a noun phrase in the sentence where the noun phrase term is not included in the input CV lexicon. We extracted a total of 1,080 drug-CV pairs (38 targeted cancer drugs and 470 CVs) from MEDLINE sentences and 2,469 pairs (40 targeted cancer drugs and 877 CVs) from MEDLINE abstracts.

Unlike drug-CV pairs extracted from FAERS or CVAROD, which are hard to evaluate, pairs extracted from MEDLINE have associated abstracts which can be used for manual curation. We extracted a total of 1,080 drug-CV pairs from MEDLINE sentences and then manually curated these pairs. We used the local MEDLINE search engine to retrieve all the sentences (8,590 in total) wherein the pairs appeared. We then manually classified these 1,080 drug-CV pairs into three classes (CAUSE, TREAT, and NONE) using the sentences (and abstracts when necessary) as evidence. Three curators with graduate degrees in biomedical sciences independently performed the curation. It took an average 25 hours for each curation in annotating these sentences. Majority vote was used to decide the final classification.

**Correlation analysis** We investigated whether drug-drug pairs that shared CV events also tended to share gene targets. We downloaded a total of 10,478 drug-gene pairs from DrugBank [19], a knowledge base for drugs, drug actions, and drug targets. These downloaded drug-gene pairs included a total of 24 targeted cancer drugs. For drug-drug pairs that shared different numbers of CV events, we calculated the average number of shared gene targets.

We investigated whether drug-drugs that shared CV events also tended to share drug metabolism genes. We downloaded a total of 4,399 drug-gene pairs from PharmGKB (the Pharmacogenetics and Pharmacogenomics Knowledge Base) [20], a public repository of genotype and phenotype information relevant to pharmacogenetics. The drug-gene pairs were assigned with subtypes Pharmacokinetics (“PK”) and Pharmacodynamics (“PD”). These downloaded drug-gene pairs included a total of 25 targeted cancer drugs. For drug-drug pairs that shared different numbers of CV events, we calculated the average number of shared metabolism genes.

1 Results

1.1 Description of tcTKB

tcTKB is comprised of a total of 14,351 unique drug-CV pairs extracted from five data sources, representing 45 targeted drugs and 1,842 CV events (Table 2). From the FDA drug labels, we extracted a total of 259 drug-CV pairs, representing 15 targeted drugs and 75 CV events. Unlike pairs extracted from the other three data sources, pairs extracted from FDA drug labels are mainly known true positives. From FAERS, we extracted a total of 11,173 drug-CV pairs, representing 39 targeted cancer drugs and 1,095 CV events. These CV events were reportedly associated with targeted cancer drugs in patients in real-world settings and included many CV events that have not yet been captured in the FDA drug labels. We extracted a total of 1,160 drug-CV pairs from CVAROD for 31 targeted cancer drugs and 300 CV events. This number is 10 times smaller than the number of pairs extracted from FAERS. It is unclear why significantly fewer CV events were reported in CVAROD than in FAERS although the numbers of targeted cancer drugs in both databases are comparable. From MEDLINE sentences, we extracted 1,080 drug-CV pairs for 38 targeted cancer drugs and 479 CV events. From MEDLINE abstracts, we extracted 2,469 drug-CV pairs representing 40 cancer
targeted drugs and 877 CV events. The numbers of drug-CV pairs extracted from MEDLINE were smaller than that from FAERS; however, these pairs contained 40 out of the 45 targeted cancer drugs. A total of 3,515 drug-CV pairs were extracted from JCO articles. These pairs included all 45 targeted drugs, demonstrating that JCO articles is good data resource for targeted anticancer drugs.

### 1.2 Drug-CV pairs extracted from four data sources are largely complementary

We investigated overlaps of drug-CV pairs extracted from FDA drug labels, FAERS, CVAROD, MEDLINE, and JCO. As shown in Table 3, the information in these four sources overlaps, but is largely complementary. Column 2 in Table 3 represents the percentages of drug-CV pairs from FDA drug labels that were also included in the other data sources. Row 2 represents the percentages of drug-CV pairs from the other three data sources that were captured in the FDA drug labels. As shown in both column 2 and row 2, many of the known drug-CV pairs in FDA drug labeling appeared in the other four data sources: 95.8% in FAERS, 46.7% in CVAROD, 38.2% in MEDLINE, and 71.4% in JCO (column 2). However, the opposite is not true. Only very small percentages of drug-CV events reported in other data sources were captured in FDA drug labels (row 2). This low percentage may be due to the following reasons: First, FDA drug labels contain only 15 targeted drugs, while the other data sources contained more targeted drugs. Second, while the drug-CV pairs extracted from FDA drug labels are mostly true positives, the pairs extracted from the other sources may contain false positives and unknown true positives.

Only small percentages of pairs from FAERS were included in other data sources: 2.2% in FDA drug labels, 10.1% in CVAROD, 7.4% in MEDLINE, and 15.3% in JCO (column 3). In addition, a majority of drug-CV pairs from other data sources (except CVAROD) were not included in FAERS (row 3). This indicates that drug-CV pairs contained in FAERS are largely complementary to those in FDA drug labels or MEDLINE. Drug-CV pairs contained in CVAROD are a subset of the pairs from FAERS as 96.7% of the 1,160 pairs also appeared in FAERS. Drug-CV pairs extracted from MEDLINE are largely complementary to those in the other three data sources. For example, only 4.0% of pairs from MEDLINE appeared in FDA drug labels, 33.1% in FAERS, and 12.2% in CVAROD (Column 5). The opposite is also true. Only 38.2% drug-CV pairs from FDA labels, 7.4% from FAERS, and 26.0% from CVAROD also appeared in MEDLINE. It is also evident from the table that full-text articles contain much information not captured in MEDLINE abstracts. For example, only 23% drug-CV pairs from JCO articles also appeared in MEDLINE abstracts.
Figure 2: Ranked precisions at 11 recalls for drug-CV pairs from CVAROD ranked by three ranking measures: frequency (Freq), proportional reporting ratio (PRR) and phi coefficient (PhiCorr). Data for relative reporting ratio (RRR), reporting odds ratio (ROR), and information component (IC) IC are similar to that for PRR and not shown.

</tbody>
</table>

#### 1.3 Ranking drug-CV pairs from CVAROD

Drug-CV pairs extracted from CVAROD may contain false signals. We compared six ranking algorithms in prioritizing extracted drug-CV pairs using drug-CV pairs extracted from the FDA drug labels as goldstandard. In our previous study in extracting drug-CV pairs from FAERS, we demonstrated that ranking by frequency significantly improved the precisions of top-ranked pairs as compared to other statistical ranking methods including RRR, ROR, RR, IC. Here we investigate whether the same is true in ranking drug-CV pairs extracted from CVAROD. As shown in Fig.2, ranking based on frequency is more effective than ranking based upon the other five approaches. The precision of top-ranked pairs (at recall = 0.1) is 0.16 as measured with drug-CV pairs extracted from FDA drug labels as gold standard. This still low precision indicates that it is likely that many true positives among the top-ranked pairs from CVAROD have not yet been captured in FDA drug labeling. This is reflected by the modest overlap between pairs extracted from FDA drug labels and pairs extracted form CVAROD (Table 3).

#### 1.4 Manual curation of drug-CV pairs extracted from MEDLINE sentences

We manually curated all 1,080 drug-CV pairs extracted from MEDLINE sentences. We did not curate the 1,389 pairs that only co-occurred in MEDLINE abstracts but not in sentences. Among the 1,080 pairs, 525 pairs (48.6%) were true positives (“drug CAUSE CV”), 356 pairs (32.9%) were “drug TREAT CV” pairs, and 199 pairs (18.5%) had no obvious semantic relationships (“drug NONE CV”) (Table 4). Moreover, among the 525 true positives, 477 pairs (90.8%) were not included in FDA drug labels.

#### 1.5 Positive relationship between shared CV events and shared drug target genes

We investigated whether drug-drug pairs that shared CV events also tended to share gene targets. A positive relationship between these two entities could indicate a causal relationship between drug targets and the observed cardiovas-
cicular adverse events associated with targeted anticancer drugs. This indication could in turn open up the possibility of predicting unknown CV events by systematically studying their gene targets and discovering novel drug off-targets, such as targets related to cardiovascular systems, instead of tumor cell growth, based on observed cardiovascular events. As shown in Figure 3, there exists a positive relationship between shared CV events and shared gene targets for drug-drug pairs. For instance, the average number of shared gene targets was 1.678 for all drug-drug pairs (cut off \( \geq 0 \)). The number significantly increased to 2.122 for drug-drug pairs that shared at least 250 CVs (cutoff \( \geq 250 \)) and to 3.857 for drug-drug pairs that shared at least 450 CVs (cutoff \( \geq 450 \)).

Since drug metabolism is responsible for many known drug-related adverse events, we then investigated whether the observed CV events were related to drug metabolism. Any positive correlations between CV events and drug metabolism genes could open up the possibility of predicting drug-associated CV events in specific cancer patients based on their metabolism genotypes (personalized cancer care). As shown in Figure 4, there is a strong positive correlation between CV events and drug metabolism genes. Drug-drug pairs that shared more CV events tended to also share more metabolism genes. The average number of shared metabolism genes for all drug-drug pairs (cutoff \( \geq 0 \)) was 0.39. The number significantly increased to 0.583 for drug-drug pairs sharing at least 250 CV events (cutoff \( \geq 250 \)) and 1.375 for pairs sharing at least 450 CV events (cutoff \( \geq 450 \)). In summary, both gene targets and metabolism genes positively correlated with targeted cancer drug-associated CV events, indicating that the observed CV events may have discoverable genetic causes and that we can predict unknown cardiotoxicities and achieve personalized cancer care by systematically studying drug-associated gene targets and metabolism.

2 Discussion

In this study, we built a comprehensive CV toxicity knowledge base for targeted cancer drugs (tcTKB) by extracting drug-CV pairs from five large scale and complementary data sources. We manually curated all drug-CV pairs that appeared in MEDLINE sentences. We systematically analyzed the correlations between the observed CV events and drug-associated gene targets and demonstrated that tcTKB, in combination with other drug-related data, represents a unique knowledge base for our understanding targeted anticancer drugs and their associated CV adverse events.

Nonetheless, our study has several limitations and can be further improved in the future. First, even though tcTKB includes many drug-CV pairs, it remains unknown what the actual precision and recall of these pairs are. For example, it is difficult to measure how many of the drug-CV pairs in tcTKB are true positives (including both known and unknown positives) and how many of them are true negatives. In addition, even though we used four large datasets in constructing tcTKB, we don’t know what the coverage of this knowledge base is. There may be drug-CV pairs in existence in other data sources, such as patient electronic health records (EHRs).
Figure 4: Relationship between shared CV events and shared metabolism genes.

Second, we observed positive relationship between CV events and drug-associated gene targets. As was previously discussed, the drug-CV pairs in tcTKB may contain noise, which can affect the observed correlations. However, we expect that the noise shall not systematically correlate with drug gene targets. Systems approach to studying drug-CV associations in tcTKB, as done for the widely used protein-protein interaction (PPI) data (which also contains noise and is largely incomplete) may generate many insightful biological hypotheses.

Third, in order to further stratify drug-CV pairs in tcTKB by patient characteristics, we need detailed information about patient characteristics. Patient demographics information can be extracted from MEDLINE abstracts [22], full-text JCO articles as well as FAERS. In the future, we will enrich tcTKB with patient demographics information.

Last but not least, we only extracted cardiovascular events associated with targeted cancer drugs in this study. In the future, we will extract richer sets of toxicities that are associated with targeted cancer drugs, including neurotoxicities, nephrotoxicities, heptotoxicities, and hematotoxicities, and develop systems approaches to studying these observed drug phenotypes in order to understand the molecular mechanisms underlying these toxicities.

Acknowledgement

Xu and Wang have jointly conceived the idea, designed and implemented the algorithms and prepared the manuscript. We would like to thank the three curators from ThinTek for the manual curation.

Abstract

The purpose of this study was to identify barriers and facilitators to patient-provider communication when discussing breast cancer risk to aid in the development of decision support tools. Four patient focus groups (N=34) and eight provider focus groups (N=10) took place in Northern Manhattan. A qualitative analysis was conducted using Atlas.ti software. The coding yielded 62.3%-94.5% agreement. The results showed that 1) barriers are time constraints, lack of knowledge, low health literacy, and language barriers, and 2) facilitators are information needs, desire for personalization, and autonomy when communicating risk in patient-provider encounters. These results will inform the development of a patient-centered decision aid (RealRisks) and a provider-facing breast cancer risk navigation (BNAV) tool, which are designed to facilitate patient-provider risk communication and shared decision-making about breast cancer prevention strategies, such as chemoprevention.

Introduction

Breast cancer is the most common cancer among women in the U.S. Known risk factors include family history, BRCA genetic mutations, benign breast disease, and reproductive history1. The Gail model or breast cancer risk assessment tool (BCRAT) may be used to calculate a woman’s absolute 5-year and lifetime risk of breast cancer, based upon her age, race, reproductive history, family history, and benign breast disease2. A woman is considered high risk of developing breast cancer if her 5-year risk is ≥ 1.67% or lifetime risk is ≥ 20%. Chemoprevention refers to taking medications for the primary prevention of cancer. Anti-estrogens, such as selective estrogen receptor modulators (SERMs) and aromatase inhibitors (AIs), have been shown in randomized controlled trials to reduce breast cancer incidence by up to 50-65% among high-risk women3,7. Based upon this evidence, the U.S. Preventive Services Task Force and other professional organizations recommend that clinicians discuss chemoprevention with high-risk women4-10. An estimated 15% of women, age 35-70 years, in the U.S. may be eligible for chemoprevention11, but fewer than 5% of high-risk women offered an anti-estrogen agree to take it12. Reasons for low chemoprevention uptake include lack of routine breast cancer risk assessment to identify high-risk women, insufficient knowledge about anti-estrogens on the part of clinicians and patients, and multiple competing demands in the primary care setting12,13. Discussions about chemoprevention represent an opportunity for risk communication and shared decision-making (SDM) to elicit patient preferences and enhance patient-provider communication. Because there is limited knowledge on the part of patients and providers about breast cancer risk assessment and chemoprevention, we developed decision support tools targeting both groups, which will be integrated into clinic workflow. The tools we are developing are a patient-centered decision aid (DA), RealRisks, and a provider-facing breast cancer risk navigation (BNAV) tool to increase breast cancer chemoprevention in the primary care setting.

A study that conducted a systematic review on patient-reported barriers and facilitators to SDM concludes that it is not that patients do not want to play a role in SDM, but it is because they can’t due to various structural, predisposing, interactional, and preparatory factors. The authors suggest that patient-reported barriers should be considered with provider-reported barriers for intervention and implementation14. The purpose of this study was to identify barriers and facilitators in patient-provider communication when discussing breast cancer risk. In order to obtain new information and learn from patient/provider perspectives, we conducted separate focus groups with patients and providers to collect qualitative data. By integrating the results we obtain from this study to the decision support tools, we will be able to further develop the tools to facilitate communication in patient-provider encounters and possibly allow SDM to take place.
Methods

Participants

In June 2013, we conducted four patient focus groups among English-speaking women recruited from Northern Manhattan in New York, NY. Women who participated in a community database through the Columbia Community Partnership for Health were contacted via email or telephone. Each focus group consisted of 7-9 women. A total of 34 women that reside in the Washington Heights/Inwood community participated. Eight key informant interviews of primary care providers (PCPs) of 1-3 participants each (N=10) were conducted at Columbia University Medical Center (CUMC). At CUMC, PCPs practice at 6 locations of the Ambulatory Care Network (ACN) clinics in Northern Manhattan. The patient population is over 80% Hispanic or African American with a predominantly Medicaid/Medicare payer mix. All participants provided written informed consent to audio-recording of a 90-120 minute facilitated session and completion of a brief survey. Patients and providers were given modest incentives of $40-$50 for participation. The study was approved by the institutional review board at CUMC.

Description of the RealRisks Decision Aid

RealRisks is a patient-centered DA that models patient-provider dialogue and incorporates experience-based dynamic interfaces to communicate numeric and probabilistic concepts that are central to breast cancer risk and chemoprevention. It is designed to improve: 1) accuracy of risk perceptions; 2) self-efficacy to engage in a collaborative dialogue about breast cancer risk and chemoprevention; and 3) decision satisfaction. The narrative is based on a fictitious character named Rose, who engages in discussions about breast cancer risk with family, friends, her PCP, and specialists. We have segmented the narrative into the following modules: 1) Risk (what is risk, breast cancer risk factors); 2) Chemoprevention (chemopreventive agents, risks/benefits). RealRisks will be tailored to a woman’s risk, so she will be reviewing only the modules that are most relevant to her. Embedded within the narrative of RealRisks are games of experience-based risk interfaces, based upon our previous work. For example, the first game is about breast cancer risk for an average 50-year-old woman and conveys how time (5-year, lifetime) affects risk with a pictograph of 100 clickable women. Players are instructed to click until they ‘find’ a woman with breast cancer. Players continue to click (e.g., sample from the population of 100 women) to better learn the meaning of a given pre-set probability (e.g., 12 out of 100 women or 12%). A similar game will be adopted in the chemoprevention module to accurately represent the benefits of chemoprevention and the risks of side effects. Accuracy of risk perceptions is important to informed decision-making given that patients may over-estimate their breast cancer risk or the risks of side effects to chemopreventive agents, such as tamoxifen.

Description of the BNAV tool

BNAV uses a two-pronged approach to improve knowledge among PCPs on chemoprevention. One component is the web-based chemoprevention toolbox, a repository of information and resources that is modeled based on the Theory of Planned Behavior. It includes: 1) standard guidelines and a self-paced interactive educational guide (attitudes); 2) video testimonials and a social component that includes the ability to compare their performance against aggregate, anonymous data of their peers (subjective norm); 3) a repository of their patients’ breast cancer risk assessments, along with the action plans based upon their patients’ interactions with RealRisks (perceived behavioral control). Based on appointment scheduling data, a provider would receive a periodic notice of upcoming patients that meet high-risk criteria so as to encourage access to the chemoprevention toolbox, which will be sent as an email or text. The second component of BNAV is embedded within the electronic health record (EHR). Within the ambulatory care dashboard in the EHR used by our PCPs, flagged alerts of patients that meet high-risk criteria for breast cancer with their personalized risk profiles will appear with their mammogram results.

Conducting the Focus Groups

Skilled facilitators (ANA, KDC, RK) led the focus groups using detailed guides. For the patient focus groups, the discussion guide included questions on breast cancer risk factors, BRCA genetic testing, chemoprevention, and discussing breast cancer risk or genetic testing with providers. The discussion guide for the provider focus groups covered questions about genetic testing, chemoprevention, EHR, and communicating breast cancer risk with patients. All sessions were audi-taped.

Data Analysis

For the qualitative analysis, two investigators (HY and TX) independently read the transcript from the first completed patient and provider focus groups to develop the initial codes and coding templates. We identified meaningful segments within the responses and assigned codes using an editing style analysis. Discrepancies in
coding were negotiated at weekly research meetings. HY and TX independently read and coded the remaining focus group transcripts, applying the coding template, which was iteratively modified as the analysis proceeded. We grouped codes into general themes and discussed the themes among the entire team of investigators. The team collectively selected the themes and representative quotes we presented in this paper. Atlas.ti 7.0 software (Atlas.ti GmbH, Berlin, Germany) was used to facilitate qualitative data management and analysis. All transcripts were uploaded into the software to enable investigators to do coding, build the codebook, and group the codes into themes. A final comparison of coding across patient interviews yielded 62.3%-94.5% agreement.

Results

Participant Characteristics

Patients

The majority (61.8%) were Hispanic and mean age was 53.4 years (range, 35-75). Forty-one percent met criteria for low numeracy, defined as a score of 0-5 (range, 0-9)\textsuperscript{30}. Everyone had access to the internet, including 88% who regularly used a computer. In terms of breast cancer risk factors, 8 (23.5%) women had a first-degree family history of breast cancer and 4 (12.9%) had a prior benign breast biopsy. According to the BCRAT (excluding 3 women with a history of breast cancer), mean absolute 5-year and lifetime risk were 1.11% (range, 0.2%-4.3%) and 7.46% (range, 2.8%-14.6%), respectively, and 3 women (9.7%) met high-risk criteria for breast cancer (≥1.67% 5-year risk).

Providers

To inform the development of BNAV, we conducted individual interviews of 10 physicians affiliated with New York Presbyterian Hospital-Columbia University Medical Center's Ambulatory Care Network (ACN). The majority were female (70%) and they were diverse by race/ethnicity (5 white, 3 black, 1 Hispanic, 1 Asian). They represented various subspecialties in primary care (6 Internal Medicine, 2, Family Medicine, 2 Gynecology) and a range of years in clinical practice (1-35) and years using an EHR (2-10).

**Barriers to communicating risk**

Based on the focus groups, time constraints, lack of knowledge, low health literacy, and language barriers emerged as the main barriers to communicating risk. The results showed that time was considered as the most significant barrier for both patient and provider groups when communicating risk. As shown in Table 3, patients thought providers “don’t have so much time to explain” and “the office visit is very hurried.” They also mentioned not being able to discuss personal circumstances with their providers because of the short amount of time. Providers also talked about the limited time they have with patients. Patients having questions towards the end of the visits was another issue related to time pressure. To worsen the situation, they said that “this encounter with the patient and the physician are getting so long” due to various interest groups trying to take part, which means there is less time to have discussions that the patients and providers would like to have. Patient’s lack of knowledge was discussed as a barrier to both groups. Patients said, “Because we don’t have the knowledge and don’t ask, the doctor won’t give it to you.” Providers seemed to think that patients do not know much about medical terms and risk-related numbers, which makes it difficult to communicate risk. Providers mentioned low health literacy as an obstacle for patient-provider communication. Since providers are not aware of the patient’s health literacy level, they said, “My struggle is how to get this information across without creating more anxiety with the health literacy issues.” The language barrier in a largely Spanish-speaking community in Northern Manhattan was also discussed as an obstacle. Providers experienced difficulty when explaining risk to patients mainly due to language and cultural barriers.

<th>Sample quotations</th>
</tr>
</thead>
</table>
| Time constraints   | *Patient* \  
                      Usually when you go to see the doctor, they don’t have so much time to explain. \  
                      Since the office visit is very hurried, five or seven minutes, he doesn’t have time to go over my personal circumstances. \  
                      Even if you have so many questions, the doctor will come out and tell you that they have other patients to see and they don’t have time. \  
                      *Provider* \  
                      The time in the doctor’s room is pressured. \  
                      A lot of time they don’t realize what it’s about and they bring it up at the end. In that case, when I’ve already spent 45 min with them and we only have 15 min., then it does open this Pandora's box. |
Facilitators to communicating risk

Information needs, desire for personalization, and autonomy emerged as facilitators to patient-provider communication through the dialogue (Table 4). Patients showed strong interest in obtaining more information. They said that this information does not have to be from a doctor and they are willing to learn from various sources (“I think it’s important that you have more places to ask questions about breast cancer, even if that person might not be my doctor. It might be a site, a nurse”). Not only will this information help them understand the doctor’s explanation, but also will help them “feel more comfortable”. They also mentioned having many questions they want to ask when
they are at their doctor’s office (“Half the time when we are at the doctors, we want to ask ten thousand questions”). Providers also had information needs. They said that they are willing to participate in courses that provide information on breast cancer. Desire for personalization was addressed in the patient focus groups. Patients said, “I wouldn’t blindly follow a doctor’s recommendations if it’s a general recommendation. I want it to be individualized.” However, providers point out that patients who do not need certain services (e.g., cancer screening, genetic testing) are receiving them, and those who need them are not. Patients are eager to participate in clinical decision-making and are willing to reach out to other medical groups if necessary. Providers also notice this strong interest in autonomy among patients. They think “this patient population really wants to learn and be involved” during the patient-provider encounters. However, providers seem to be frustrated when patients value doctor’s opinion less and think they know what should be done.

Table 4. Quotations on facilitators and information needs to communicating risk.

</thead>
<tbody>
<tr>
<td>Desire for personalization</td>
<td><strong>Patient</strong>&lt;br&gt;I wouldn’t blindly follow a doctor’s recommendations if it’s a general recommendation. I want it to be individualized. [sic]&lt;br&gt;The doctors are reading off of a script. They recommend the same thing for all of us. […] It doesn’t seem personal at all. <strong>Provider</strong>&lt;br&gt;The other point is again what you’re discussing is a real public health issue on both sides. Women who do not need mammograms are getting mammograms and women who need genetic testing are not getting that. This is a process of education and it’s a long process in that area. The investment has to be done in the high school, PTA, and make mothers and students alike aware that it’s very important.</td>
</tr>
<tr>
<td>Autonomy</td>
<td><strong>Patient</strong>&lt;br&gt;Shouldn’t they do it for whoever wants to have it done?&lt;br&gt;But unfortunately we all need to be very proactive and never accept no for an answer.&lt;br&gt;I would consult not just my doctor but I would also consult some other medical type groups to see what I could do.&lt;br&gt;We all have to remain clear on what we want. How is it that we learn what we want? If you don’t know what breast cancer is, then how do you go to a doctor and say I’d like to get checked for breast cancer. <strong>Provider</strong>&lt;br&gt;I think this patient population really wants to learn and be involved. I’ve worked with other patient populations where they want my opinion less and they know or they think they know the right answer and that was frustrating. I really think this patient population wants to have these discussions.</td>
</tr>
<tr>
<td>Information Needs</td>
<td><strong>Sample quotations</strong></td>
</tr>
</tbody>
</table>

**Patient**<br>I think it’s important that you have more places to ask questions about breast cancer, even if that person might not be my doctor. It might be a site, a nurse.<br>I am more informed so I can have a better discussion and I can understand his responses better. I know more terms. I don’t know if it will get me to talk
about it with my doctor but I will feel more comfortable.
You know, you don’t want to walk away and not knowing.
Half the time when we are at the doctors, we want to ask ten thousand questions, we forget what to ask.

Provider

Facilitator: Yeah so it would be like those 20 minute talks but more relevant to the primary care providers on how to assess risk and who should get genetic testing and that type of thing. So if we made this a requirement to take this course online, do you think that would be helpful? Absolutely. Yeah and I would definitely be interested.

Discussion

In summary, patients and providers consider time, lack of knowledge, low health literacy, and language barriers as obstacles to communicating risk. On the other hand, information needs, desire for personalization, and autonomy are discussed as facilitators that may enhance communication in patient-provider encounters. However, discordance between patient and provider expectations about good clinical practice still exists and may hamper SDM. We will use this information to inform the development of RealRisks and BNAV to facilitate communication about breast cancer risk.

By integrating an education component in RealRisks, the health literacy and lack of knowledge issues can be addressed. Educational materials can be presented in various versions to target patients with different levels of understanding. Including a Spanish version of the material will help overcome language barriers since there are many Hispanic patients. Also, patients can learn about breast cancer through RealRisks whenever they want to, which will not only fulfill their information needs, but also their needs to gain information from sources other than doctor visits. When further developing BNAV, a health literacy indicator could help providers determine the health literacy level of each of the patients, and therefore, result in a level-appropriate approach when explaining risk. In addition, an education toolbox can be implemented to educate providers about breast cancer risk that will inform discussions with their patients.

RealRisks and BNAV can address the time issue that was the biggest concern during both patient and provider focus groups. By interacting with RealRisks, patients can receive education before meeting with providers, which can reduce time spent on providers explaining risk and related concepts. This could allow time for discussing patients’ preferences, which is a component in SDM. Patients’ strong interest in autonomy and personalization will also enhance risk communication and SDM. Integrating patient’s needs and preferences with provider’s expertise and other resources, SDM could help patients make informed medical decisions.

This study has several limitations. The sample size of patients and providers was relatively small. In addition, a large proportion of our study patients were Hispanic, an ethnic group which is often under-represented in clinical studies. Our results may not be generalizable to populations from other geographic regions; however, Hispanics are the largest minority group in the U.S. We also only included physicians and did not collect data from other primary care providers (e.g., physician’s assistants, nurse practitioners), who may be targeted in future studies.

We believe that RealRisks and BNAV can facilitate patient-provider communication and possibly lead to SDM when the barriers are dealt with and facilitators are integrated as discussed. For future studies, since a majority of the patients are Hispanic, it would be interesting to integrate communication facilitators that target this ethnic group. In a study that compared Hispanic and Non-Hispanic women’s needs in patient-provider communication, the results showed that Hispanic women experienced difficulty during the communication process because of language barriers and health literacy, which is consistent with our results. Interestingly, while a warm communication style was important for Hispanic women, information needs were crucial for Non-Hispanic women. It would be meaningful to conduct research on how to include ethnic-specific communication styles into our tools and examine whether the further developed tool was effective in enhancing patient-provider communication.

This research will allow patients to gain a better understanding of their breast cancer risk, along with their PCPs, which will inform risk-based screening and prevention strategies (e.g., genetic testing, chemoprevention). Our goal
is to maximize benefits, minimize harms, and promote more efficient allocation of health services, particularly for high-risk individuals.

Abstract
Herbal and dietary supplement consumption has rapidly expanded in recent years. Due to pharmacological and metabolic characteristics of some supplements, they can interact with prescription medications, potentially leading to clinically important and potentially preventable adverse reactions. Electronic health record (EHR) system provides a valuable source from which drug-supplement interactions can be mined and assessed for their clinical effects. A fundamental prerequisite is a functional understanding of supplement documentation in EHR and associated supplement coverage in major online databases. To address this, clinical notes and corresponding medication lists from an integrated healthcare system were extracted and compared with online databases. Overall, about 40% of listed medications are supplements, most of which are included in medication lists as nutritional or miscellaneous products. Gaps were found between supplement and standard medication terminologies, creating documentation difficulties in fully achieving robust supplement documentation in EHR systems. In addition, in the clinical notes we identified supplements which were not mentioned in the medication lists.

Introduction
The popularity of herbal and nutritional supplements in the United States (U.S.) has expanded rapidly in recent years. The American Botanical Council reported that nearly 6 billion dollars are spent on herbal supplements in the U.S. in 2013. The Center for Disease Control reports that around half of U.S. adults use some form of dietary supplements. Recently, the National Center for Complementary and Integrative Health (NCCIH, formerly the National Center for Complementary and Alternative Medicine) published the National Health Statistics Reports reporting that about 40% of Americans use some form of complementary and alternative medicine (CAM) and that nonvitamin/nonmineral dietary supplements were still the most commonly used complementary health approach among adults in 2002 (18.9%), 2007 (17.7%) and 2012 (17.7%). Among these, fish oil supplements (7.8%), glucosamine chondroitin, or a combination (2.6%) were found to be the most commonly consumed supplements (2012 National Health Interview Survey). The use of melatonin and probiotics has also dramatically increased from 0.6% and 0.4% in 2007 to 1.3% and 1.6% in 2012, respectively.

CAM therapies are typically used to complement conventional medicine with the goal of reaching a better healthcare outcome, although less than 5% of U.S. adults exclusively used CAM therapy approaches. One in four persons taking a prescription medicine also take an herbal supplement, increasing the possibility of drug-supplement interactions (DSIs). For example, warfarin can interact with various supplements such as Panax ginseng and Ginkgo biloba leading to severe adverse effects such as spontaneous postoperative bleeding. St. John’s Wort has also attracted attention as it lowers blood concentrations of cyclosporine, amitriptyline, digoxin, indinavir, and warfarin, potentially resulting in severe clinical syndromes. Another clinical study reported that volunteers receiving digoxin and St. John’s Wort had a 25% decrease in the concentration of digoxin in blood plasma. Unfortunately, the ability to readily identify adverse effects of herb and dietary supplements and their reactions with conventional Western medications is not well studied and the reports on such interactions occur less frequently in clinical practice.

DSIs are most often due to an inhibitory or synergistic interactions between drugs and supplements with similar genes or molecular pathways within the body. Before market approval, new drugs are usually tested for interactions with other drugs through pharmacology experiments and clinical studies. Testing for interactions between new drugs and supplements, however, are not required due to the differences in regulatory requirements for supplements, as delineated in the Dietary Supplement Health and Education Act of 1994 (DSHEA). The DSHEA rules designate supplements as food, which requires appropriate labeling and adherence to food safety rules. However, since supplements are not regulated as typical medications, they do not need to meet the usual clinical approval trials for
safety and effectiveness, which includes assessment of medication pharmacology and potential drug-drug interaction characteristics. As such, post-market surveillance through pharmacoepidemiology studies and other standard mechanisms which are often used to detect adverse events in a given population are not required. These methods are limited, moreover, as they can only focus on a small set of drugs or supplements.

Electronic Health Record (EHR) systems are the main communication and documentation platform for healthcare providers. They store a large amount of data on drug prescribing behaviors, adverse drug events, and patient symptoms, thus providing a rich source of observational data offering the potential for active surveillance. Most current efforts use structured data such as diagnoses to find drug interactions and adverse drug events. These experiments often miss important information in clinical notes that can be leveraged for further clinical research and knowledge discovery. Unstructured texts can be analyzed using natural language processing (NLP) techniques for patient cohort identification, phenotype extraction, and drug-related information extraction.

To facilitate effective mining of EHRs for DSIs, a better understanding of how the EHR represents the supplements and how effective the term coverage is for both structured clinical data and unstructured clinical notes is needed to extract accurate and comprehensive supplement information from the EHR. To the best of our knowledge, the investigation of supplement term representation and coverage on EHR systems is limited and deserves further investigation. One possible reason for the lack of extensive studies on DSIs is an absence of a standard and accepted terminology for herbal supplements. In a recent study comparing terms with different resources, we found that none of five major online databases covered all supplement terms. In this study, we sought to evaluate supplement term coverage between online supplement databases and EHR patient data. We also sought to investigate the adequacy of standard terminologies for representing supplements existing in the EHR.

**Background**

In this section, we introduce five online databases used to form a supplement list and the standard terminologies we evaluated for representing supplements.

**Supplement databases**

**Natural Standard Authority Database (NSAD)**

NSAD is a database set up by Natural Standard, a research collaboration including physicians and researchers. There is a grade given to each entry, which reflects the level of evidence-based literature available about each product and its use. Each entry has an overview of the supplements, common names all over the world, uses, warnings, contraindications, mechanism of action, and a literature review. In addition to having entries for each of the supplements, there is an adverse reaction checker, an effectiveness checker, interactions display and a search for pregnancy related information.

**Medscape**

Medscape is managed by the WebMD health professional network; the material is provided by physicians and authorities in that field. Medscape provides author attribution and sources of information making it a reliable source. Medscape also features a list of searchable entries and a tool which allows users to check for drug or supplement interactions.

**Natural Medicines Comprehensive Database (NMCD)**

NMCD is managed by the therapeutic research center. The database has over 1,000 terms, but allows users to search in several other languages. Under each product, the effectiveness of the supplement, safety, known interactions with drugs, mechanism of action, and adverse reactions are listed. The information is targeted at physicians, researchers, and pharmacists. There is a separate advanced search for physicians which can used to make clinical decisions. This database also has an interactions checker and a search tool which lets users search with common names, scientific names or brand names making it one of the most useful and comprehensive databases.

**MedlinePlus**

MedlinePlus is a web-based information service provided by the U.S. National Library of Medicine (NLM). It has a health topic section, a drug and supplements section and several other tools. This service including the drug and supplement database is maintained by the National Institutes of Health and is aimed at the general public. The information is provided by the National Center for Complementary and Alternative Medicine, National Toxicology...
Program, and the Office of Dietary Supplements. Each entry is followed by a journal style list of references for that supplement.

*Drugs.com*22

Drugs.com provides popular supplements with efficacy, side effects and interactions with drugs. The information is targeted at consumers and the format is user-friendly. Drugs.com also has a pill identifier and an interactions checker that lets users search for every potential interaction a drug will have with other drugs, supplements or food. Interactions are further classified as severe, moderate or mild. Information is derived from Wolters Kluwer Health Inc.

**Unified Medical Language system (UMLS) and MetaMap**

UMLS is a repository that integrates over 100 medical vocabularies from many sources and provides a unified platform which can be used to develop or enhance applications. One of the components in the UMLS is a Metathesaurus which has over 2 million terms and codes from many different vocabularies like Systematized Nomenclature of Medicine - Clinical Terms (SNOMED CT), Current Procedural Terminology (CPT), Logical Observation Identifiers Names and Codes (LOINC), etc. For this paper, UMLS was used to normalize data from different sources (i.e., EHR and online databases). Each concept in the UMLS Metathesaurus has a Concept Unique Identifier (CUI), which can be used to compare data from different sources.

MetaMap is a natural language processing tool developed by the NLM to automatically map biomedical texts to UMLS Metathesaurus. It is able to lexically and syntactically analyze the texts and provide a list of mapping concept candidates with mapping scores.

**RxNorm, NDF-RT, and RxMix**

The NLM creates a standardized nomenclature of clinical drugs called RxNorm from a source of 12 drug vocabularies. RxNorm has unique identifiers for each drug along with the drug’s dosage, generic name, chemical components, and dosage forms.23

National Drug File - Reference Terminology (NDF-RT) is a part of the Veteran Health Administration’s National Drug File. It is able to classify drugs into formal categories in addition to giving information about their molecular interactions, kinetics, therapeutic categories, and dose forms.24

RxMix is a web application that allows users to combine various functions from the RxNorm and NDF-RT application program interfaces (APIs) to create custom applications that can be run interactively or in a batch mode.25 We used this tool for mapping terms to RxNorm and NDF-RT concepts.

**Methods**

We first extracted supplement terms from both online databases and structured medication lists in EHRs, and then formed a comprehensive list of supplements followed by a search for the terms in clinical texts. All terms from online resources, medication lists, and clinical texts were mapped to UMLS, RxNorm and NDF-RT. Then, we compared the term coverage for the three resources (Figure 1).

**Extraction of supplement list from online databases**

To identify the selected databases, we performed an Internet search for the top herbal supplements databases to identify the selected databases. Any databases without support by evidence or with very short (<50) supplement lists were excluded. Databases no longer updated or maintained were also rejected for this study. We finally selected the five popular online databases: NSDA, Medscape, NMCD, MedlinePlus, and Drugs.com as the sources of herbal and dietary supplement terms. We extracted all supplement terms from databases and manually excluded the non-English words from online databases. A combined list of supplements was finally generated from online databases for further analysis.

**Extraction of supplement terms from clinical data**

We collected patients’ medication lists from the University of Minnesota Medical Center, Fairview Health Services (FHS) during a four-year period of 2011-2014. University of Minnesota institutional review board approval was obtained and informed consent was waived for this minimal risk study.

The collected medication list from FHS were processed by using the following steps:
• Step 1: A physician (coauthor EA) manually reviewed medication lists to select supplement terms;
• Step 2: Supplements related information such as the frequency of supplement usage and their assigned pharmaceutical class (e.g., Nutritional Products), were extracted and analyzed to provide a better understanding of how supplements are represented in the medication lists;
• Step 3: The list of supplements was mapped to the UMLS by using MetaMap. Only exact matches with a perfect score of 1000 were considered and retrieved;
• Step 4: The supplement list was also mapped to standard terminologies RxNorm and NDF-RT by using RxMix25. We specifically used the RxNorm:findRxcuiByString and NDF-RT:findConceptsByName functions to extract the concepts.

Collection of supplement terms from clinical texts
We collected clinical texts from FHS during the same period, and analyzed the clinical texts using the following steps:
• Step 1: Instead of manually reviewing charts to find the supplements, we first combined the supplement lists extracted from both online databases and medication lists to form a comprehensive list;
• Step 2: The comprehensive list (blue dashed lines in Figure 1) was then used as a dictionary to search all clinical texts to investigate if these terms existed in the clinical texts;
• Step 3: To normalize the supplement terms, we mapped these supplement terms to UMLS, RxNorm and NDF-RT, the same as steps 3&4 when mapping medication list in the above section.

Evaluation of supplements term coverage
We evaluated the term representation in medication lists based on their frequency and assigned classes. After supplement terms were mapped to UMLS, RxNorm and NDF-RT, we then evaluated the gap between the current
terminologies to the existing terms. We used Venn diagrams to compare the term coverage of these concepts to see how they overlap with each other to provide a visual and quantitative assessment.

Results

Extraction of supplement list from online databases, clinical data and clinical texts

We extracted 3,115 unique supplement terms from the five online databases, 3,720 unique terms from medication lists, and 4,717 terms from clinical notes.

In the whole medication list in the EHR, we found about 40% of the listed medications are related to supplements. Among these supplements extracted from the EHR medication lists, most of them were classified as Nutritional Product (41.7%) and Miscellaneous Products (40.7%). Other types include Gastrointestinal Agents, Hematological Agents, Gastrointestinal Agents, and other types (Table 1). The top frequent supplements in the medication list include Fish oil, Glucosamine chondroitin, Probiotics, Melatonin, Coenzyme Q10, etc.

Evaluation of supplements term coverage

As shown in Figure 2, after mapping these terms to UMLS and specific standard terminologies, we obtained 1,683, 897, and 1,937 UMLS concepts, 556, 1,410, and 1,733 RxNorm concepts, and 421, 367, and 576 NDF-RT concepts from online databases, medication lists and clinical texts.

Figure 2. Number of terms or concepts in each resource after mapping to the UMLS, RxNorm and NDF-RT.
For all three resources, over 60% of terms cannot be mapped to UMLS concepts, and even much less to RxNorm and NDF-RT. The number of mapped UMLS concepts is larger than RxNorm and NDF-RT for online databases and clinical notes, but the EHR medication list returns more RxNorm concepts than UMLS and NDF-RT concepts.

After mapping to the various terminologies and comparing the concepts coverage between three resources, we found that all concepts extracted from the medication list were a subset of those in the clinical notes. The concepts in both the medication list and the clinical notes have different degrees of overlap with those in online databases. In other words, clinical notes contain all supplement concepts in the medication list and part of the online databases while online databases do not contain all concepts existing in the EHR.

Figure 3. Venn diagram showing the supplement term coverage between online databases, medication list, and clinical notes after mapping to (A) UMLS concepts, (B) RxNorm concepts, and (C) NDF-RT concepts.

We further investigated those supplements, in clinical notes but did not include them in the supplement list (shown in Figure 3), and listed a few selected supplements with their occurrences in example sentences (Table 2). Many of them are related to history of food consumption, allergy problems and recommendation to take or avoid a specific supplement either due to risk of potential drug interactions or due to the known physiologic effects of the supplements. But we also found that patient was actually taking or using that supplement, such as Goat’s rue.
Table 2. Supplements only mentioned in clinical texts and not in the medication lists. Supplements are underlined in the examples.

Discussion

DSIs are attracting more attention recently due to their known and potential adverse effects on patient safety. Many clinical studies have found potential interactions, although they focused on a small subpopulation. In addition, use of EHR data for DDI and drug adverse effects has been widely investigated, while only limited study has focused on mining EHR data to explore DSIs. This research investigates how EHR data represent herbal and dietary supplements and evaluates existing terminologies to represent the supplements in EHR systems. This paper studies DSIs by first establishing a list of supplements from a variety of sources and then identifying the coverage of the supplements in the medication lists and notes of an EHR system.

It is not required to document supplement usage in the EHR system, so it is surprising to find that about 40% of the medications documented in the EMR are herbal and dietary supplements. Unsurprisingly, the most frequently used nonmineral/nonvitamin supplements in the medication lists are consistent with the top 10 supplements listed in a recent report of US consumption of supplements.4 In the medication list, there is no easy way to identify the supplements other than manual review. The reason is that there is not a class called herb or dietary supplements or similar, and most of them are classified as nutritional or miscellaneous products. There are still 3% of nutritional products and 40% of miscellaneous products that are non-supplements.

The supplement names are similar to drugs in that they have many ways to represent them with common names or trade names. Many names in the medication lists are the combinations of two or more ingredients, connected by either “-”, “/o” and/or “w/”, such as “Alpha Lipoic Acid-Cr-Cinnamon”, “Zinc Citrate-Phytase”, “Prenat-FeFum-FePo-FA-Omega 3”, “Prenat w/o A-FeCbGI-DSS-FA-DHA”, and “B-Complex w/ C-Biotin-D-Zinc & Folic Acid”. Many names also contain information of enteral formulation such as “Tab” (i.e., Tablet), “Cap” (i.e., Capsule), parenteral formulations, such as “(Bulk) Powder”, “(Bulk) Granules”, “Crystals”, “Liquid”, and dosage information such as “200 MG”, “100 MG/ML”. These supplements with dosage and formulation information and those containing multiple ingredients were neither mapped to the UMLS concepts nor mapped to other terminologies. We did not perform a normalization step before mapping to keep some detailed information which can be recognized by RxNorm. Moreover, separating the combined supplement names into each of the ingredients is not meaningful. The RxNorm was designed to identify drugs with detailed information, so the terms with different dosages can be linked to their unique RxNorm concepts, although missed mappings still exist. For example, two supplements with the same ingredients and different dosages “Alpha Lipoic Acid (Thioctic Acid) Cap 200 MG” and “Alpha-Lipoic Acid (Thioctic Acid) Cap 300 MG” were mapped to the same UMLS concept “C0023791:.ALPHA.-L IPOIC ACID [Organic Chemical,Pharmacologic Substance,Vitamin]”, but they have their own unique RxCUIs: 313841 and 333831, respectively. This is one reason why the number of mapped unique UMLS concepts is less than RxNorm concepts for supplements in the medication lists. Another reason is that many terms cannot find suitable UMLS concepts, but can be related to RxNorm concepts. For example, “Cinnamon Tab 500 MG” does not have an exact match in UMLS but does have a unique RxCUI of 6459.

A gap between terminologies and supplements in EHR was also observed. Terms with multiple ingredients cannot be mapped and were treated differently from those listed with one of these ingredients. Many terms with detailed dosage information can only be partly mapped to UMLS concepts with a mapping score lower than 1000, in which cases we treated them as non-mapped terms. NDF-RT has less coverage than the other two for the supplements. Not only for those terms with multiple ingredients or detailed information but also some general supplement terms such as “Chia Oil” and “Garlic” which cannot be mapped to NDF-RT. Thus, none of these terminologies can be used to represent all the supplement terms in the EHR system.

Considering many forms of a single supplement name, we mapped and normalized them to UMLS, RxNorm, and NDF-RT concepts before comparing the term coverage. By searching supplement lists both in online databases and medication lists, we found that all terms in the medication list were included in the list generated from clinical notes,
which makes sense as clinicians usually import the current medication list as part of the clinical notes. About 64% of terms in the online databases were mentioned in the clinical notes, indicating the wide consumption of supplements. The lower overlap of UMLS concepts between the medication lists and major online databases may be due to the mapping issues mentioned above. But they have higher overlap 37% in RxNorm than 26% in UMLS concepts. The possible reason is that RxNorm is more sensitive to the supplements with detailed information than UMLS.

There are some supplements in clinical notes that are not mentioned in the medication lists. For example, “We discussed avoiding aloe vera for the potential interaction with cyclosporine” indicates the clinician realized the potential DSI between aloe vera and cyclosporine and suggested the patient to not use aloe vera. A mother also tried an herb supplement called goat’s rue to increase alveoli. The supplement marijuana was also mentioned as a clinical history component and relates to the patient’s strange behavior. Adenosine shows up in the notes but not in the medication list as it is a provider administered medication used as an acute therapy. Such medications may only show in the documentation as provider orders or as clinical note documentation as they would not have a role as a chronic medication.

We also found similar terms but not exactly the same names in both clinical notes and medication list. One example, “Cranberry juice” is in the clinical notes, but the medication list only has “CRANBERRY JUICE EXTRACT PO”, which does not exactly match with the UMLS concept “C1572601:CRANBERRY JUICE [Food]” (score of 694). Since we only include supplements with exact matches, we excluded this from the supplement list extracted from the medication list. Although some supplements existed in both sources but notes provide additional information; for example, “[ginkgo] increased risk for bleed especially since taking aspirin - reviewed with pt.” infers potential interactions between ginkgo and aspirin. Other examples include “Ginkgo has been shown to inhibit hepatic glucuronidation of MPA in vitro.” and “Medication Changes: He had been taking ginkgo but read an article that said it should not be taken with warfarin so he stopped taking it about 2 days ago.” This also suggests to us that it is necessary to complement unstructured data with structured data for obtaining comprehensive information from the EHR.

This pilot study has multiple limitations. We only collected clinical data from one site – FHS, during the limited period of 4 years, which may underestimate the term coverage in the EHR. When mapping to UMLS, we only considered the exact matches, so this brings lower returned concepts from UMLS. We did not distinguish reported alimentary facts from medical facts at the current stage. Moreover, it may have bias when we searched supplements in clinical notes by comparing with the supplements generated from the other two sources. The best way is to manually review, but that would be costly in terms of time and labor.

Conclusion

We evaluated supplement term coverage in the EHR by comparing with the existing online resources. Forty percent of medication lists are supplements and they are mostly categorized as Nutritional Products or Miscellaneous Products. All supplements in the medication lists were also mentioned in the clinical notes. We found there is a gap between standard terminologies and supplements in the EHR and not a single standard terminology can cover all supplements in the EHR. Moreover, clinical notes contain additional information such as suggestion or discussion of supplements existing in the medication lists as well as those supplements not mentioned in the medication lists.

Abstract

Using longitudinal data in electronic health records (EHRs) for post-marketing adverse drug event (ADE) detection allows for monitoring patients throughout their medical history. Machine learning methods have been shown to be efficient and effective in screening health records and detecting ADEs. How best to exploit historical data, as encoded by clinical events in EHRs is, however, not very well understood. In this study, three strategies for handling temporality of clinical events are proposed and evaluated using an EHR database from Stockholm, Sweden. The random forest learning algorithm is applied to predict fourteen ADEs using clinical events collected from different lengths of patient history. The results show that, in general, including longer patient history leads to improved predictive performance, and that assigning weights to events according to time distance from the ADE yields the biggest improvement.

Introduction and Motivation

Drug safety is a critical public health issue, with the prevalence of hospital admissions caused by adverse drug events (ADEs) ranging from 2.4% to 12.0%¹,²,³. Although the safety of a drug must be evaluated in clinical trials prior to its launch, there are potentially many undiscovered side effects due to limitations in terms of both the number of participants and follow-up time. In fact, many drugs have been withdrawn from the market for causing fatal ADEs, such as Vioxx for its doubled risk of causing myocardial infarction⁴ and Cerivastatin for causing fatal rhabdomyolysis⁵. The continued surveillance of drug safety, post marketing, is therefore of utmost importance. Currently, this activity is almost exclusively dependent on spontaneous reports⁶, i.e., voluntary reporting of ADEs by patients or clinicians. Research on using alternative data sources, such as electronic health records (EHRs), are, however, emerging⁷,⁸,⁹. The use of EHRs for pharmacovigilance has several advantages that can complement and compensate for some of the weaknesses of spontaneous reports, such as under-reporting of ADEs and limited access to patient history¹⁰. An important property, and advantage, of EHRs is that they record longitudinal observations of patients and their treatment, including drug use. This opens up great opportunities for analyzing the temporal relationships between ADEs and other clinical events, which, in turn, can aid in the detection of ADEs.

In comparison to spontaneous reports, the reporting of ADEs in EHRs is better regulated, yet the problem of under-reporting remains¹¹. To improve the reporting of ADEs, given the large amounts of data archived in EHR systems, manually screening all records to identify ADEs that were not reported is obviously very costly and even unrealistic. Instead, systems that employ machine learning methods are more efficient – and perhaps not less effective – by learning patterns from patients who have ADEs encoded in their medical history and detecting patients that have suffered an ADE, yet in whose records it has not, but should have, been encoded. Employing such systems could result in improved reporting of ADEs and, in the long run, potentially reduce the unsafe use of drugs.

There are two parallel approaches for such systems to facilitate the reporting of ADEs: (1) to prospectively predict whether there are ADEs to report in new health records; and (2) to retrospectively detect ADEs that are missing in earlier health records. Both approaches require the underlying models to include information from patients’ medical history, given that the first approach needs to use patient history to train the predictive models. The problem thus boils down to making meaningful use of patient history information in EHRs in order to detect ADEs. This problem has previously been studied from different perspectives, such as how best to represent clinical events¹²,¹³. In this study, we focus on the temporal aspect, i.e., which time periods should be considered when collecting clinical events for predicting ADEs. This aspect is expected to have a high impact on the resulting predictive performance, as the probability of an adverse event of a drug occurring at a certain point in time is highly dependent on when the drug was taken, e.g., an ADE will typically not occur for the first time years after a drug has been taken. On the one hand,
considering longer time periods may lead to the ADE signal drowning in the volumes of collected information, while, on the other hand, shorter time periods may exclude information that is crucial for making accurate predictions.

In previous research, a few studies have touched upon or analyzed temporal relationships in EHRs for detecting ADEs. Norén et al. monitor clinical events that have occurred before and after a drug is prescribed to look for abnormalities as signals indicating ADEs\textsuperscript{14}. Their study is, however, in a different genre as it does not involve a learning procedure. At the same time, Jin et al. transform the temporal problem onto a cross-section problem by defining hazard period, effect period and reference period after a drug is prescribed\textsuperscript{15}. In a recent study, Eriksson et al. extract clinical notes and structured prescription data between drug introduction and discontinuation and then filter ADEs based on time stamp inconsistency between structured data and notes\textsuperscript{16}. However, all of these studies mainly look at the temporality on a rather detailed level, such as between specific events or predefined periods; how to handle the temporality in EHRs in general still remains unanswered. In this study, the scope is set to detecting ADEs that should be reported in EHRs by employing machine learning methods to learn patterns using clinical events, and hence the essence of the problem is how to model the events that occurred at different time points in the patient history. To the best of our knowledge, this is the first study to explore ways of handling the temporality of patient history prior to an ADE. The aim of this study is therefore two-fold: (1) to investigate various ways of handling the temporality of clinical events; (2) to explore the importance of clinical events at different time points for detecting ADEs.

**Materials and Methods**

In this section, we first introduce the strategies of handling temporality that are proposed in this study. Then, we describe a series of empirical experiments that are conducted to evaluate the proposed strategies, starting by describing the data source and subsequently the details of each experiment.

**- Strategies to handle temporality**

Three strategies – *bag of events*, *bag of binned events*, and *bag of weighted events* – to handle the temporality of clinical events in patients’ medical history for the detection of ADEs were proposed and evaluated in this study. In each of the strategies, only clinical events that occurred prior to the target ADE were included. A toy example of handling the temporality of one drug, one diagnosis and one clinical measurement in a time period of three days is demonstrated in Figure 1.

Here, let \( x \) denote each unique event in the whole EHR database, \( d \) denote the number of days prior to the occurrence of the target ADE, \( d \leq D \), and \( n_d \) denote the number of times \( x \) occurred in day \( d \).

- **Bag of Events (BE)** This strategy counts the number of occurrences of event \( x \) within \( D \) days. In this case, the value of feature \( x \) is \( \sum_{d=1}^{D} n_d \).

- **Bag of Binned Events (BBE)** This strategy counts the number of occurrences of event \( x \) in each day within \( D \) and represents \( x \) as \( x_1, x_2, ..., x_D \). The value of the corresponding feature here is \( n_1, n_2, ..., n_D \).

- **Bag of Weighted Events (BWE)** This strategy assigns different weights to event \( x \) that occurred at different days \( d \) and takes into account the weights when counting the number of occurrences of \( x \). The proportional weights are assigned according to the time distance between the event and the target ADE: events that occurred further in time from the target ADE receive proportionally less weight. In this case, the time distance between \( x \) at day \( d \) and the target ADE is \( d \), and hence the value of feature \( x \) is \( \sum_{d=1}^{D} (n_d / d) \).

**- Data source**

In this study, data was extracted from the Stockholm EPR Corpus\textsuperscript{17}, which contains health records of around 700,000 (anonymized) patients over a two-year period (2009-2010), obtained from Karolinska University Hospital in Stockholm, Sweden. This database contains large amounts of diagnosis information, drug administrations, clinical measurements and clinical notes in free-text. In this study, we used only the structured data, i.e., diagnoses, drugs and clinical...
Figure 1: Strategies to handle temporality of three clinical events during three days

measurements, as features. In the Stockholm EPR Corpus, diagnoses are encoded by the International Statistical Classification of Diseases and Related Health Problems, 10th Edition (ICD-10) and drugs are encoded by the Anatomical Therapeutic Chemical Classification System (ATC). This research has been approved by the Regional Ethical Review Board in Stockholm (Etikprövningsnämnden i Stockholm) with permission number 2012/834-31/5.

The targeted use case in this study is to detect patients who should, but do not, have a specific ADE reported in their health records by retrospectively analyzing clinical events in their medical history. Among the diagnosis codes that indicate ADEs\(^\text{\ref{ADE}}\), category A.1 (a drug-related causation was noted in the diagnosis code) and category A.2 (a drug- or other substance-related causation was noted in the diagnosis code) were considered in this study. We selected the 14 most frequent A.1 and A.2 codes in the Stockholm EPR Corpus, and thus created 14 datasets, where the existence of the diagnosis code indicating a particular ADE was used as the class label in each dataset. The classification task is hence binary: positive or negative towards a specific ADE. Both inpatients and outpatients are included in this study, where the positive examples are patients whom have been assigned an ADE-specific diagnosis code and the negative examples are patients whom have been assigned a similar diagnosis code to the diagnosis code indicating ADE. Here, similarity is defined as two codes sharing the same first three levels of the ICD-10 concept hierarchy. For instance, if the positive examples are patients with diagnosis code \(G44.4\) (drug-induced headache), the negative examples are patients with any diagnosis code starting with \(G44\) (other headache syndromes), but not \(G44.4\). Table 1 lists the basic descriptions of each dataset, including the diagnosis code that indicates the corresponding ADE (dataset name), the description of this code and the number of positive and negative examples.

Around 10,000 unique ICD-10 diagnosis codes, 1,500 unique ATC codes and 730 unique clinical measurements exist in the Stockholm EPR Corpus. Since most clinical events only occurred to a small group of patients, the datasets where clinical events are used to describe each patient are consequently both high-dimensional and very sparse, i.e., for a single observation (or example) the vast majority of the features have a value of 0. The employed algorithm for generating predictive models, i.e., the random forest algorithm\(^\text{\ref{random_forest}}\), is rather efficient in handling high-dimensional data, as only a small random sample of the available features is considered when determining the best way of partitioning the training examples during tree growth. However, for highly sparse data, it is not unlikely that all sampled features are uninformative, i.e., lead to no separation. Unless specifically handled, the tree growth will terminate prematurely and lead to an overall low predictive performance. Rather than employing any of the more sophisticated approaches to handle this\(^\text{\ref{sparse_data}}\), we here employed the quite straightforward approach of removing features that are more sparse than 99%, i.e., the ones for which non-zero values were observed in fewer than 1% of the patients; for the datasets with fewer than one hundred observations, features with only one non-zero value were also removed. The motivation behind this is simply that for features with very few non-zero values, the impact of applying different strategies to handle temporality will be negligible, even though some of these features might be valuable indicators.

In this study, we defined the following 12 thresholds from patient history: 1, 2, 3, 4, 5, 6, 7, 14, 21, 30, 60, 90 days before the target ADE, where, for each threshold \( n \), clinical events that occurred \( n \) days before the target ADE are studied. The choice was made with the assumption that more clinical events would have occurred in the days closer to the ADE and the difference between days closer to the ADE has a higher impact on detecting ADEs, especially on the ones that are dose-independent. We therefore studied clinical events that occurred in each day of the first week, followed by each week in the first month, and finally every month up to 3 months (90 days) before the occurrence of the target ADE. In the *bag of binned events* strategy, clinical events are binned within a time threshold. For example, all events that occurred one day before ADE are binned in day 1, and all events that occurred from 60 days to 90 days before the ADE are binned in day 90. Here, the same event that occurred at different times is treated as different events, the number of features in *bag of binned events* is hence much higher than the other two strategies. To reduce the number of potential models, we do not distinguish between the events that occurred in different days within, e.g., the third month before the ADE. The average number of features and sparsity over the 14 datasets, before and after removing the extremely sparse features at each time threshold, are illustrated in Figure 2.

![Figure 2: Average number of features and sparsity before and after removing extremely sparse features](image)

**Experiments**

In this study, a series of experiments was conducted to evaluate the strategies to handle temporality of clinical events in patient history and explore the impact of using different lengths of patient history on detecting ADEs. In the first experiment, the three strategies — *bag of events*, *bag of binned events* and *bag of weighted events* — were compared by employing the random forest\(^9\) learning algorithm to features (clinical events) generated by each of them respectively.
When more than two competing models are compared, the Friedman test was employed for statistical testing of the null hypothesis that all models perform equally, followed by a post-hoc test using the Bergman-Hommel procedure. The choice of random forest was made due to its reputation of achieving high accuracy, its ability to handle high-dimensional data, as well as the possibility of obtaining estimates of variable importance. The algorithm constructs an ensemble of decision trees, which together vote for what class label to assign to an example that is to be classified. Each tree in the forest is built from a bootstrap replicate of the original instances, and a subset of all features is sampled at each node when building the tree, in both cases to increase diversity among the trees. When the number of trees in the forest increases, the probability that a majority of trees makes an error decreases, given that the trees perform better than random and that the errors are made independently. Although this condition can only be guaranteed in theory, the algorithm has often been shown in practice to result in state-of-the-art predictive performance. In this study, we used random forest with 500 trees. In all experiments, models were built and evaluated using stratified 5-fold cross-validation with two iterations, where the original class distribution was retained in each fold.

The considered performance metrics are accuracy, area under the ROC curve (AUC), precision, recall, F-score and area under the precision-recall curve (AUPRC). Accuracy corresponds to the percentage of correctly classified instances. AUC depicts the performance of a model without regard to class distribution or error costs by estimating the probability that a model ranks a randomly chosen positive instance ahead of a negative one. Precision measures the fraction of true positives among all the predicted positives, while recall, also known as sensitivity, measures the fraction of true positives among all the positives in the gold standard. In the case of detecting ADEs, high precision means that the algorithm is able to detect more true ADEs than false ones, while high recall means that the algorithm is able to detect most true ADEs. F-score describes the harmony between precision and recall by calculating $2 \times \frac{(\text{precision} \times \text{recall})}{(\text{precision} + \text{recall})}$. Only both high precision and high recall can yield a high F-score. AUPRC depicts the probability that precision is higher than recall for each recall threshold. It is considered to be a more careful measurement compared to AUC, since high AUC often leads to high AUPRC, but not necessarily the other way around.

In a subsequent set of experiments, variable importance generated with random forest using bag of binned events was analyzed in order to obtain a deeper understanding of in which time period clinical events are more informative. Variable importance can be estimated in different ways. In this study, Gini importance was chosen as the variable was analyzed in order to obtain a deeper understanding of in which time period clinical events are more informative.

Each tree in the forest is built from a bootstrap replicate of the original instances, and a subset of all features is sampled at each node when building the tree, in both cases to increase diversity among the trees. When the number of trees in the forest increases, the probability that a majority of trees makes an error decreases, given that the trees perform better than random and that the errors are made independently. Although this condition can only be guaranteed in theory, the algorithm has often been shown in practice to result in state-of-the-art predictive performance. In this study, we used random forest with 500 trees. In all experiments, models were built and evaluated using stratified 5-fold cross-validation with two iterations, where the original class distribution was retained in each fold.

Friedman tests were conducted to compare the three strategies at each time threshold over the 14 datasets (p-values are shown in Table 2). P-values are not available for time threshold $l$ day since the three strategies are identical for
clinical events that occur one day before the ADE. From this table we can see that the p-values generally decrease with more days of patient history, and the null hypothesis that the three strategies perform equally well is rejected with most evaluation metrics towards the end, i.e., using 90 days of patient history. This indicates that when we include more days of patient history in our predictive models, the impact of how temporality is handled increases. Note that although there seems to be a performance drop from 60 days to 90 days in Figure 3, if we take a closer look at the performance on each dataset (e.g., Figure 4 for bag of weighted events), we can see that for most datasets, the predictive performance improves from 60 days to 90 days, except for a big drop on two (G620 and L271), which explains most of the overall performance drop observed in Figure 3.

</table>

Given these results, a post-hoc analysis comparing the strategies pairwise was carried out with 90 days as threshold; the results are shown in Table 3. The left half of the table shows the average rank – the lower the rank, the better the performance – among the three strategies, and we can see that bag of weighted events is consistently better than the other two. The pairwise p-values in the right half of the table indicate that bag of weighted events is significantly better than bag of events for AUPRC, precision and F-score; bag of weighted events is significantly better than bag of binned events for AUC and AUPRC; and bag of binned events is significantly better than bag of events for AUC.

- Impact of temporality on specific adverse drug events

The predictive performance of the best observed strategy – bag of weighted events – for each specific ADE is presented in Figure 4. As described in the previous section, the predictive performance overall increases on a small scale towards

using more days of patient history, which is especially clear for D642, T808 and T887. Even with an obvious drop at the end on e.g. G620, the predictive performance with 90 days is still higher than it is with 1 day. Apparently, the choice of threshold has different degrees of impact on different ADEs.

**Figure 4: Predictive performance of random forest with bag of weighted events for each ADE**

To obtain a deeper understanding of the contribution of clinical events from different days of patient history to the predictive performance, variable importance analysis was conducted using bag of binned events, where they are treated as different variables. Figure 5 shows the relative importance of clinical events occurring in different days of patient history for detecting each specific ADE. For most ADEs, it is clear that clinical events occurring in the late stage of patient history, e.g., just one day before the ADE, is of highest importance; for some ADEs, such as D642 and G620, clinical events occurring in a much earlier stage of patient history are relatively more important.

**Discussion**

For the task of detecting ADEs using clinical events in EHRs, the predictive performance with the three strategies differs from each other within a fairly small range, even though there are significant differences observed. This can be explained by the difficulty of the task itself. Here, in each dataset, the positive examples are patients who have a specific ADE, while the negative examples are patients who have a disease that is in the same family as the ADE (they share the first three levels of ICD-10). In many cases, these patients are very similar to each other in terms of having similar drugs and clinical measurements; therefore it is difficult for the learning algorithm to distinguish between them. Hence it is difficult to observe big changes in predictive performance with different strategies since they are all bounded with the similar clinical events these patients share.
Based on our results, the random forest built with \textit{bag of events} has the worst predictive performance, followed by \textit{bag of binned events}, and both of them are, in most cases, outperformed by the random forest built with \textit{bag of weighted events}. This finding is consistent with the granularity of each of the strategies: the model with \textit{bag of events} completely ignores temporality, and hence is the crudest model; although the model with \textit{bag of binned events} treats events from different time periods as different features, such a representation also results in increased dimensionality and sparsity that have a negative impact on the predictive performance; and, finally, the model with \textit{bag of weighted events} tackled the problems with the other two strategies – temporality, dimensionality and sparsity – by aggregating the events from different time periods according to their time distance from the target ADE.

The predictive performance and variable importance for each specific ADE to some extent reflect the different nature of each ADE. Adverse drug events are typically divided into two types: dose-dependent or not. The former is related to the accumulation of toxics from drugs or medications; therefore, when predicting ADEs of this type, we would intuitively expect that using events from longer patient history contributes to improved predictive performance compared to using only events from the most recent days. This assumption is supported by the results on predicting \textit{D642 – drug induced anemia}, where the predictive performance improves monotonically with the use of more days of patient history (see Figure 4 – D642) and the clinical events from seven days prior to the ADE are much more important compared to one day (see Figure 5 – D642). Another example is \textit{G620 – drug induced polyneuropathy}, which is an ADE known to be caused by drugs used in the treatment of very severe or chronic diseases like cancer or tuberculosis. Such patients are normally exposed for a long period until the side effect is observed. Here, again, a similar performance trend is observed to support our hypothesis (see Figure 4 – G620 and Figure 5 – G620). On the other hand, the second type of ADE is related mainly to idiosyncratic or immunological nature, such as an allergic reaction, which indicates that most likely, with a very marginal assumption, they are more or less instant side effects from taking drugs or medications. The results on predicting \textit{T886 – anaphylactic shock due to correct drug or medication properly administered} is a good example that agrees with this assumption. The predictive performance almost remains the same as using events from only one day before the ADE (see Figure 4 – T886) and the events from one day before are absolutely the most important ones (see Figure 5 – T886).

However, the assumptions that are made above are not always reflected by our results in this study, which can be explained by several reasons. First, only clinical events from the structured EHRs are used as features here, while ADEs are often described in the notes rather than reported as diagnoses (given that ADEs are heavily under-reported as we described in the introduction). Especially for patients who suffer from severe diseases, ADEs become less
important to report. Therefore, using only the structured clinical events can hardly capture a holistic and precise picture for detecting ADEs. Second, in the real clinical setting, where the EHR data is collected, there is a lack of controls on when clinical events, especially diagnosis codes, are reported in the database. Sometimes events that occurred weeks ago are reported together with the ones that occurred one day ago when the patients are discharged. This, unfortunately, results in noise in the training data and also inaccurate weights based on the time distance from the target ADE. Third, diagnosis codes, i.e., the ICD-10 codes, are themselves heterogeneous. For example, T782 - T784 cover not only ADEs but also adverse reactions to substances that are not drugs.

One limitation of this study concerns the fact that the events are represented as a bag in all of the strategies, which neglects the temporality between the events in the same day or period. This has a potential impact on the predictive performance, especially for predicting ADEs that are not dose-dependent, since the temporal relationship between events within a short period is important to capture when the ADEs are mostly instant effects. To take this into account, techniques that enable mining event sequences would be useful. In addition, the use of ICD-10 codes to select patients with and without ADEs should be proceeded with caution due to the fact that they are coded also for billing purposes and other reasons. For future work, it would also be interesting to see the impact of the proposed strategies on the task of distinguishing patients who have ADEs from patients who do not, i.e., the negative examples would be randomly selected from the population. The way of assigning weights in bag of weighted events is fairly crude and harsh; a follow-up study could focus on exploring alternative ways of assigning weights to clinical events that occur at different time points. To improve the predictive performance, including free-text clinical notes in the models and handling the temporality of information in notes are indeed worth investigating.

Conclusions

It is advantageous to use longitudinal data from electronic health records for the detection of adverse drug events. This study proposed and evaluated three strategies to handle temporality of clinical events: drugs, diagnosis and clinical measurements. These strategies differ from each other in how they take into account the clinical events that occur in different days of patient history: bag of events counts the number of times that an event occurred without regard to when it occurred; bag of binned events separates the patient history into predefined bins and then counts the number of times that an event occurred in each bin; and bag of weighted events counts the weighted number of times that an event occurred, where the weights are assigned proportionally according to time distance between the event and the target adverse drug event. Based on our empirical investigation, the bag of weighted events strategy yields the best predictive performance with the considered metrics. Here, we conclude that, in general, using longer patient history leads to improved predictive performance, and the temporality of clinical events matters more when using more days of patient history.

Abstract

Decision support tools increasingly integrate clinical knowledge such as medication indications and contraindications with electronic health record (EHR) data to support clinical care and patient safety. The availability of this encoded information and patient data provides an opportunity to develop measures of clinical decision complexity that may be of value for quality improvement and research efforts. We investigated the feasibility of using encoded clinical knowledge and EHR data to develop a measure of comorbidity interrelatedness (the degree to which patients’ co-occurring conditions interact to generate clinical complexity). Using a common clinical scenario—decisions about blood pressure medications in patients with hypertension—we quantified comorbidity interrelatedness by calculating the number of indications and contraindications to blood pressure medications that are generated by patients’ comorbidities (e.g., diabetes, gout, depression). We examined properties of comorbidity interrelatedness using data from a decision support system for hypertension in the Veterans Affairs Health Care System.

Introduction

The combined forces of an aging population and rising rates of chronic disease have resulted in a rapid increase in the number of adults experiencing multimorbidity, or multiple chronic conditions (MCCs).1,2 The presence of MCCs generates a number of challenges for health care delivery. As a patient’s number of chronic conditions increases, there is an associated rise in physician visits, prescriptions, hospitalizations, and home health services.1,3-6 Patients with MCCs are also at greater risk for mortality and more rapid functional decline.1,7-10

For clinicians, patients with MCCs present unique challenges because of the need to address multiple health issues, often during a brief clinic visit and in the face of competing psychosocial demands.11-13 Patients and their providers may also have different priorities regarding which of a patient’s conditions are most important.14 Traditional multimorbidity measures such as the Charlson score15,16 often incorporate disease burden, but may not capture the full complexity involved when caring for patients with MCCs. Newer conceptual frameworks for multimorbidity have started to incorporate biological, socioeconomic, cultural, environmental, and behavioral health determinants.17 We previously proposed a framework that also includes comorbidity interrelatedness, or the degree to which patients’ co-occurring conditions interact to generate clinical decision-making complexity.18 In order for these frameworks to influence clinical practice, however, there is a need to operationalize constructs such as comorbidity interrelatedness so that they may be applied to quality improvement, performance evaluation, and research efforts.

Knowledge-based decision support tools integrate clinical knowledge (e.g., information about potential medication interactions) with electronic health record (EHR) patient data to provide clinicians with tailored messages about optimal therapy choices for specific patients. Such tools may also provide an opportunity to quantify measures of
clinical complexity such as comorbidity interrelatedness. The objective of this study was to test the feasibility of harnessing encoded knowledge and EHR data to calculate a comorbidity interrelatedness score, and to explore this domain’s properties in a population. Using a common clinical scenario—decisions about blood pressure medications in patients with a hypertension diagnosis—we determined the degree to which comorbidities influence medication decisions in patients with MCCs, and examined variation in this phenomenon across a population.

Methods

ATHENA-HTN

In order to test the feasibility of constructing a comorbidity interrelatedness score, we obtained encoded knowledge and patient-level EHR data from a study of a clinical decision support (CDS) module, ATHENA-HTN. ATHENA-HTN presents detailed patient-specific evidence-based recommendations for hypertension management to primary care providers at point-of-care.19-23 ATHENA-HTN includes a knowledge base (KB) that models hypertension knowledge in computer-interpretable formats. A guideline interpreter (execution engine) processes EHR data (e.g., diagnoses, medications, blood pressure values, and laboratory test results) and generates automated patient-specific recommendations for medications using information from the KB (Figure 1).19 The KB was created with Protégé, a widely used open-source knowledge acquisition software using the EON model24-26 In developing the KB, clinical knowledge from hypertension guidelines and other sources was reviewed and discussed with subject matter experts then entered manually into the Protégé KB. Medication indications and contraindications derived from published guidelines, pharmacology textbooks, and subject matter experts.27-29 The current project took advantage of this encoded clinical knowledge to calculate comorbidity interrelatedness scores for patients enrolled in the ATHENA-HTN study.

Figure 1. Derivation of a comorbidity interrelatedness score that integrates patients’ electronic health record data with encoded clinical knowledge from a hypertension decision support tool to determine the degree to which an individual’s chronic conditions influence clinical decisions about hypertension.

The current analyses use a dataset from a clinical implementation study of ATHENA-HTN in which patient-level clinical data (e.g., comorbidities) were linked to encoded knowledge about comorbidity-drug class interactions.30, 31 The study population for the ATHENA-HTN trial comprised Veterans Affairs (VA) patients with an ICD-9-based diagnosis of hypertension who had one or more primary care clinic visits with an enrolled provider during the study period. Because ATHENA-HTN is designed to provide treatment recommendations for patients with primary
hypertension who are suitable for standard hypertension guidelines, the study excluded patients who could be identified as having secondary hypertension, those on 5 or more antihypertensive agents, and those who had other circumstances such that standard guidelines would not apply (for example, patients who were under 21 years; patients who were pregnant; patients with spinal cord injury, narcolepsy, ascites, hypertrophic cardiomyopathy, or a home-bound clinical state; and patients with active prescriptions for medication(s) that indicated standard guidelines would not apply such as transplant drugs). The study using ATHENA-HTN was approved by the Human Subjects Panel, Stanford University, and the Research and Development (R&D) Committee, VA Palo Alto Health Care System.

**Patient Selection for Feasibility Study**

We obtained data for 5,997 individuals in the ATHENA-HTN study database who had a blood pressure reading above goal at their first clinic visit during the study period. Blood pressure goals were defined using VA/Department of Defense guidelines at that time (i.e., < 140/90mmHg for patients without diabetes and < 140/80mmHg for patients with diabetes). We focused on patients with elevated blood pressure because they represent individuals who warrant consideration for medication modification or intensification. In addition, patients with blood pressure above established goals are frequently flagged by EHR applications that aim to improve hypertension management quality of care and performance.

**Comorbidity Interrelatedness Score for Patients with Hypertension**

In developing a comorbidity interrelatedness score, we first identified comorbid conditions that commonly affect choice of hypertension medications by generating an indication or contraindication to a medication class. We considered a comorbid condition to be hypertension-related if published clinical evidence or guidelines describe interactions between the condition and one or more major anti-hypertensive drug classes. For example, clinical guidelines recommend that patients with diabetes receive an ACE-inhibitor (or an angiotensin receptor blocker) to decrease risk of cardiovascular events and progressive kidney dysfunction. Patients with osteoporosis, meanwhile, may benefit from a thiazide because these medications promote calcium reabsorption by the kidney. For patients with gout, however, thiazides should be avoided as they can increase hyperuricemia and result in a gout flare, particularly if the gout is poorly controlled. We identified the following conditions: Diabetes, Coronary Artery Disease, Benign Prostatic Hyperplasia, Depression, Obstructive Pulmonary Disease (Non-Bronchospastic), Gout, Cerebrovascular Disease, Atrial Fibrillation, Myocardial Infarction History, Heart Failure, Bronchospastic Disease, Angina, Atrial Tachycardia, Urinary Incontinence, Osteoporosis, Chronic Kidney Disease, Sinoatrial Node Dysfunction (no pacemaker), Migraine, Heart Block (1st degree), Hyperthyroidism, Heart Block (2nd/3rd degree), and Raynaud’s.

The comorbidity interrelatedness score incorporates information about the number of drug classes that are indicated or contraindicated (or both) based on a patient’s chronic conditions. We included six anti-hypertensive drug classes in the comorbidity interrelatedness measure: thiazides, ACE-inhibitors, angiotensin-receptor blockers, cardioselective beta-receptor antagonists, dihydropyridine (DHP) calcium-channel blockers, and non-DHP calcium-channel blockers. These drug classes were selected because they are commonly prescribed for hypertension. We did not include alpha-blockers, loop diuretics, or potassium-sparing diuretics in the measure because their primary indication was often a condition other than hypertension (e.g., prostatic hyperplasia, heart failure, and liver disease, respectively). Prescriptions for non-cardioselective beta-receptor antagonists, central adrenergic anti-hypertensives, direct vasodilators, and peripheral adrenergic anti-hypertensives were present for 2% or fewer subjects and were therefore excluded from the measure as well.

Figure 2 illustrates the number of anti-hypertensive drug classes that are either indicated or contraindicated in the setting of specific hypertension-related comorbidities. For each individual, we calculated a comorbidity interrelatedness score equal to the sum of all comorbidity-related drug class indications and contraindications that were generated by his or her specific conditions. For example, a patient with diabetes, gout, and depression would receive a score of 7 because gout and depression each generate a relative contraindication for a single anti-hypertensive drug class, and diabetes generates indications for five different anti-hypertensive drug classes. We also calculated the number of anti-hypertensive classes to which each individual had both an indication and a contraindication (a circumstance that generates an extra level of complexity because a provider needs to weigh the potential benefits of the medication for Condition A against the potential risks for Condition B). For the patient above, diabetes, gout, and depression generate an indication and a contraindication for thiazides and cardioselective beta-receptor antagonists (Figure 2). To examine patterns of complexity in the population, we calculated the mean
(SD) comorbidity interrelatedness score, the score distribution, and the mean (SD) number of anti-hypertension classes to which individuals had both an indication and a contraindication, for all individuals with 0 through 6 hypertension-related comorbidities.

**Results**

Table 1 describes sociodemographic and clinical characteristics of patients from the ATHENA-HTN trial who were included in this feasibility study. The mean (SD) age of patients was 71 (11), and the vast majority were male (97%). The mean (SD) number of prescribed anti-hypertensive classes was 1.6 (1.1), but 22% of the patients had three or more prescriptions. The most common comorbidities affecting anti-hypertensive class choice were diabetes (42%), coronary artery disease (33%), depression (23%), obstructive pulmonary disease (16%), gout (11%), and cerebrovascular disease (10%).

Table 2 and Figure 3 illustrate the relationship between comorbidity number and comorbidity interrelatedness for the entire population that we examined. There was a strong correlation between a patient’s number of hypertension-related comorbidities and his or her comorbidity interrelatedness score ($r = 0.845$). In addition, among patients with two or more hypertension-related comorbidities, there was a strong association between number of comorbidities and number of co-occurring indications and contraindications to the same anti-hypertension class (as occurs when a patient’s diabetes and gout generate both an indication and a contraindication to a thiazide medication). However, as illustrated by the variation in interrelatedness scores across the population in Figure 3, number of comorbidities alone did not fully capture the clinical complexity that was generated by condition interactions. For example, for patients with 4 comorbidities, the interrelatedness score ranged from 4 to 16.

Figure 3. Relationship between number of hypertension-related comorbidities and clinical complexity generated by interactions among conditions (comorbidity interrelatedness)

Discussion

This study demonstrated the feasibility of combining encoded knowledge and EHR data to calculate individual comorbidity interrelatedness scores, and examined the distribution of this construct in a population of patients with elevated blood pressure. We observed a strong relationship between number of chronic conditions and degree of comorbidity interrelatedness. However, variation in comorbidity interrelatedness among patients with similar number of conditions suggests that the construct may capture an important dimension of clinical complexity.

Our work builds on an array of complexity measures that incorporate patients’ chronic conditions into a single index or score. For example, a widely used approach is to reduce multimorbidity to a count of conditions, particularly when researchers desire a simple analytic tool to adjust for variation in comorbidity number. Other measures, such as the Charlson score, Elixhauser, and the Index of Coexisting Disease, rely on a brief list of severe
conditions and have been shown to reliably predict outcomes such as disability and mortality.\textsuperscript{36} However, these measures do not incorporate the additional clinical complexity and risks that may arise when patients’ conditions interact.\textsuperscript{11, 39-41} The comorbidity interrelatedness score that we present here is an attempt to develop an EHR-based measure that incorporates this increased complexity arising from condition interactions.

There are several opportunities to develop the comorbidity interrelatedness construct further to more fully capture clinical complexity. For example, we focused on a single index condition (hypertension) and examined comorbidities that influence decisions about hypertension treatment. An expanded measure could incorporate all of a patient’s medical condition. Algorithms could be applied to weight co-occurring comorbidities that generate an indication and a contraindication to the same drug class, or conditions that are severe and/or identified by providers as having more complicated or time-intensive management requirements. In addition, future measures could incorporate conditions or patient characteristics that do not directly affect specific medication choices but that might influence decisions about management (e.g., physical or mental health conditions, degree of frailty, or social circumstances that influence decisions about number of medications). While these characteristics are not routinely documented in all EHRs at present, there is increasing interest in patient-reported outcomes such as symptoms and functional status that could be incorporated into clinical complexity measures in the future. Developing approaches now with available data will expedite construction of systems that include more variables in the future.

Before such measures, or even the more rudimentary score that we examined in this feasibility study, can influence clinical practice and research, several challenges need to be addressed. Importantly, there is a need to validate the measure to ensure that it captures a unique clinical complexity construct. For example, future studies should examine whether clinical decisions for patients with higher comorbidity interrelatedness scores require greater provider time and effort, particularly when patients have comorbidities that generate concurrent indications and contraindications for the same drug classes. Studies should also explore whether comorbidity interrelatedness is associated with higher rates of clinical inertia (i.e., failure to make treatment decisions due to clinical complexity) or other adverse clinical outcomes. Such studies could be completed using data from an existing CDS tool like ATHENA-HTN, or with an EHR that links patient clinical data to encoded information about comorbidity-drug interactions. Additional work will also be required to consider practical implementation challenges, such as the need to continuously update the KB to ensure that it reflects current evidence about condition-medication interactions and other comorbidity relationships.

Nevertheless, there are a number of potential ways in which a validated comorbidity interrelatedness measure could be used to achieve meaningful use of EHR technology, enhance clinical care, and support research and medical education. For example, understanding the degree to which a patient’s comorbidities affect decisions about medical management could improve case mix adjustment and reward clinicians for providing clinically complex and cognitively demanding care. Some have recommended that performance measures should incorporate patient comorbidities and other characteristics,\textsuperscript{42} and a comorbidity interrelatedness score could be useful for this purpose. In addition, the proposed score and other clinical complexity measures could potentially be used to identify patients who are so complicated that standard disease-focused quality and performance measures should not apply.

**Conclusion**

This study illustrates a method for quantifying clinical decision complexity in terms of comorbidity interrelatedness. This method could be expanded to include additional clinical domains and to include patient data about functional status and social factors, as these data become available in structured format. Incorporating measures of clinical complexity into decision support tools and other data systems could offer opportunities to support clinical care and enhance performance evaluation and research focused on patients with multiple chronic conditions.

Florida International University Miami, FL

Abstract. Electronic prescribing (e-prescribing) allows prescribers to securely send electronic prescriptions directly to pharmacies using specific software [1]. Large national health policy initiatives are promoting the adoption and meaningful use of certified Electronic Health records (EHRs) with electronic prescribing (e-prescribing) capability in order to improve the safety, quality, and efficiency of healthcare delivery. A growing concern among pharmacists is the patient safety implications of new kinds of medication errors and information omissions caused might be introduced by e-prescribing [2]. Currently, pharmacists expect to receive more prescriptions electronically. Thus, they need to be aware of the unintended consequences of e-prescribing. To better understand e-prescribing systems and the potential changes in workflow of pharmacies, it is important to understand what errors are introduced by e-prescribing that did not occur with manual forms of prescribing. This study provides analysis and insight into the awareness of Florida pharmacists and pharmacy personnel of e-prescribing systems, their likelihood of using e-prescribing in their practices, their overall satisfaction with e-prescribing systems, their preference for prescribing, the principal benefits and barriers, and the main errors encountered by pharmacies in Florida.

Methodology. This study uses a cross-sectional internet-based survey administered to pharmacies. The sample consists of pharmacies located in the State of Florida. The study was reviewed and piloted by specialists and consultants before distribution. The survey is distributed online to pharmacies in different settings (such as single site, multiple sites, chain) by the head of the pharmacy association in Florida. The survey is conducted in a two-month window (i.e.: September to October 2014). 197 questionnaires are started, 150 questionnaires are returned completed, the rest are discarded from analysis.

Results. Our findings indicate that most of the pharmacies that responded are moving to adopt and use e-prescribing services in Florida. Almost 91% of our sample states that their pharmacists are equipped with an e-prescribing system and they were using it in their day-to-day practices. A total of 61% respondents indicate that they been using an e-prescribing systems between 1 and 5 years. About 30% state that their pharmacies have been using an e-prescribing system for more than 5 years. Desktop computer turned out to be the most frequently used e-prescribing device for e-prescription (97%), followed by laptop computers (6%), other devices (2%) and handheld devices (1%). A majority (59%) report that their main preference is e-prescription and only 27% indicate that they mainly prefer traditional prescribing. A total of 47% indicated that using e-prescribing system was easy to use and it can be easily incorporated into their practices. Almost 60% of the respondents are satisfied with the current e-prescription system compared to manual forms of prescribing. A total of 90% indicated that they agree with electronic access to complete patient medication histories. These results show the importance of integrated e-prescribing software with an EHR. The majority of the respondents state that the most important benefit of using an e-prescribing system is better and quicker service for patients. Service is improved due to efficiency in pharmacy workflow. The largest barrier to use is the fee paid for each transaction. Errors in e-prescribing are also listed as a barrier. The most common errors observed by pharmacy personnel are: 1) incorrect quantity, 2) wrong dose, strength or frequency, 3) duplicate therapy and unnecessary medical tests, and 4) wrong dosage form. These errors require problem solving by pharmacy personnel. In fact, pharmacy personnel indicate that the e-prescription errors are confusing. They are frustrated and annoyed when the error cannot be easily addressed. The prevalent contributing factors to e-prescription errors are incorrect calculations or data-entry errors. The most common reasons given for the source of the errors is that prescriptions are incorrectly entered by prescribers or that information is incorrectly translated from the prescriber system to the pharmacy system. Finally, the figure shows that four main factors can contribute to concerns about prescribing control substances electronically in Florida. The factors are: factors related to security, privacy and confidentiality of health records, fraud and abuse practice, concerns about time and effort spent for validation and authentication of prescriptions and costs of reporting e-prescribing functionalities, benefits and errors can help pharmacies better take advantage this service. Although e-prescribing can reduce errors related to illegible handwriting the technology itself can cause new types of e-prescription errors. These errors decrease the workflow efficiency because pharmacy personnel have to stop their work and call the prescriber to detect and resolve the errors. Pharmacists and prescribers need to be trained on the function, software interface, and integration of e-prescribing systems into their practice in order to better use of e-prescribing service. Moreover, lack of standardized e-prescribing software is considered as one of the main obstacles affecting the implementation of e-prescribing. Collaborative interaction and communication between prescribers and pharmacies by implementing a standardized e-prescribing system is a possible solution.

Conclusions. Though our study is conducted in the state of Florida, we assert it is generalizable to other US states since Florida is both geographically and ethnically diverse. However, we plan to expand our study to other states. This study is important because building awareness of

Design, Development, and Initial Application of a Systematic, Semi-Automated Predictive Analytics Framework for Health Care

Samir E. Abdelrahman, PhD, Kensaku Kawamoto, MD, PhD, MHS
Department of Biomedical Informatics, University of Utah, Salt Lake City, USA

Introduction

Predictive analytics can be leveraged in health care in various ways to identify risk factors, predict outcomes, and manage patients in an individually tailored, risk-stratified manner. For example, predictive analytics can be used to identify patients hospitalized with congestive heart failure who are at high risk of readmission, so that these high-risk patients can be monitored closely post-discharge. Despite its significant potential, however, predictive analytics is not widely leveraged in most health care settings. One of the main barriers to the widespread application of predictive analytics is the amount of expertise and time required. To address this important challenge, University of Utah Health Care sought to develop a systematic predictive analytics framework for health care, with steps in the process automated wherever possible. The current state and application of this framework are presented here.

Methods

Clinical and operational leaders at University of Utah Health Care were consulted to identify priority use cases for health care predictive analytics. Several pilot projects were completed in these areas, with each project leading to the development and refinement of the predictive analytics framework based on the use case requirements. Processes amenable to automation were identified and implemented on an iterative basis.

Results

Figure 1 outlines the predictive analytics framework, which includes a model building stage (top part of Figure) and an operational deployment stage (bottom part of Figure). Both structured and unstructured electronic health record (EHR) data may be used, with a present focus on structured data. Model building entails data collection and integration, data analysis, systematic model development, and risk factor analysis, while operational deployment entails implementation of the back-end infrastructure as well as the user-facing intervention. Clinical experts are essential for several of the steps in the framework, including the identification of potentially relevant risk factors and the design of clinical interventions. Automation has been incorporated primarily into the model building aspect of the framework, so that this aspect of the framework can largely function as an automated pipeline.

The framework has been applied to several use cases, including the prediction of congestive heart failure readmission, the prediction of clinical appointment no-shows and last-minute cancellations, the prediction of complications from medical procedures, and the prediction of patient satisfaction. Model performance has generally been strong. For example, this framework was able to predict congestive heart failure readmissions with a positive predictive value of 50% and a negative predictive value of 96%, with the area under the curve significantly higher than in previously published models.

Conclusion

A systematic and largely automated predictive analytics framework can be successfully implemented in support of efforts to improve health and health care.

5 Gunma University Graduate School

**Introduction**
The data concerning community health, such as, medical health records, health check-up, cancer screening, nurse care services have been separately stored in each their own database. The difficulty of sharing information between these regions, was in the compatibility of data. The aim of this study was to develop the Community Health Databank (EHR) for providing an efficient community health care.

**Methods**
We developed a novel electronic system utilizing a spatiotemporal tag. Used by adding a space-time tags, without relying on the existing ID, all data pertaining to an individual, it may be data aggregation on the timeline. (Figure1)
Furthermore, the developed databases is not have personal information, has a structure that can be used with confidence. (Figure2)
Using this system, we obtained PHR (personal health records) including personal individual behavioral records, medical records, and health records.
We assessed whether these records integrated appropriately and safely with independence of private information, such as name, date of birth, and address. (Figure3)

**Results**
Our system succeeded in storing the various individual health records comprehensively. Using tagged data, any information regarding health care can be shared with protection of the private information regardless of their format and style.

**Discussion**
The Community Healthcare Databank would enable an integrated approach for health care information without treating private information. Then, utilization of this bank could help to establish a standardized health care system.
Knowledge Base Acquisition For Rare Concepts Using Manual Bootstrapping
Patrick R. Alba, BA1,2, Scott L. DuVall, PhD1,2, Joanne LaFleur PhD1,2, Adam P. Bress, PharmD, MS2, Olga V. Patterson, PhD1,2
1VA Salt Lake City Health Care System; 2 University of Utah, Salt Lake City, UT

Abstract
Concept identification is an essential task of any natural language processing (NLP) system built to perform information extraction from clinical documents. It typically relies on term identification and context disambiguation. The lack of a comprehensive lexicon necessitates corpus-based knowledge base acquisition. A major challenge arises in cases when terms that represent the concept of interest are ambiguous and the concept is rarely mentioned in text, which makes manual annotation not feasible and automatic bootstrapping less efficient. We propose a method of computer assisted knowledge base acquisition that requires less effort than a manual review, and achieves a more accurate outcome than an automatic approach would in these cases.

Background
The Canadian Cardiovascular Society (CCS) angina grading scale is a generally accepted method to describe a patient’s angina severity1. An NLP system aiming to extract CCS scores from clinical notes requires an accurate and comprehensive lexicon and disambiguation model that reflect the target corpus. While the CCS scoring system is commonly used to describe angina, explicit mentions of specific scores are rare. The issue of identifying mentions of the score in documents is complicated by the highly ambiguous terms used by clinicians. For example, the abbreviation CCS is more frequently used to describe cubic centimeters rather than the Canadian scoring system. (e.g. 1000ccs of water). The two knowledge base acquisition approaches that are typically used are manual annotation or semantic bootstrapping. However, annotating a large set of random documents would not be feasible due to the rarity of the relevant concept. Automatic bootstrapping requires highly precise seed words, thus, not appropriate in this case due to the ambiguous nature of the known terms2.

Methods
The original CCS guideline provides only two relevant terms associated with the concept of interest, Canadian Cardiovascular Society score and CCS score. All available documents for a random set of 10,000 patients were retrieved from a large national database. All instances of the seed words were identified using keyword search and manually reviewed in order to discover co-occurrence patterns used by clinicians. The patterns were then iteratively applied to the full set of documents without the seed words. As new terms were discovered, they were added to the seed word list. The patterns collected through this manual bootstrapping approach were used to create or modify a series of regular expressions. Several iterations of the process were completed before no new co-occurrence patterns were discovered. These regular expressions reflected one of two types of context patterns: those that reflect the concept of interest, and those that indicate that the term represented a different concept, thus serving as a disambiguation patterns. The two sets of regular expressions served as the knowledge base for the CSS score extraction system.

Results
Using this approach, all instances of a CCS score within 1.8 million documents were reviewed by a single person in under 40 hours. While the seed words were very common, this discovery process identified that only 0.02% of the documents contained the concept of interest. The described approach was able to uncover not only the rare cases of mentioned concepts but also instances where the concept was implied. For example, the term “CCS” is implied in instances like “angina class 1” and “stage IV angina”. Though largely manual, this corpus-driven approach resulted in a comprehensive knowledge base for information extraction with limited expert input.

Conclusion
The amount of person-hours required in order to build a knowledge base using the described manual bootstrapping method is considerably less than other standard manual methods and more precise than computational methods.

Personalized medicine beyond genetics: using personalized model-based forecasting to help type 2 diabetics understand and predict their post-meal glucose

David Albers¹, PhD, Matthew Levine¹, Bruce Gluckman², PhD, George Hripcsak¹, MD MS, and Lena Mamykina¹, PhD

¹Department of Biomedical Informatics, Columbia University, New York, NY
²Department of Engineering, Pennsylvania State University, College Park, PA

Introduction
Type 2 diabetes (DM2) is a disease with dire consequences if not treated to minimize its effects, is costly ($245 billion a year in 2012), and is prevalent affecting over 8% of the US population. Treatment of DM2 relies primarily on nutrition, exercise, and medication. Because of this, self-management is an essential part of DM2 care. However, DM2, as a disease, is highly dependent on the individual and while there exist general guidelines for healthy eating, each individual with diabetes must find their own way to translate these guidelines into daily meal choices. This is usually accomplished through a lengthy, often complex and opaque, trial and error process in which individuals experiment with different foods and observe their impact on blood glucose levels. Moreover, as is the case with many complex nonlinear processes ranging from aircraft flight to the management of large industrial machinery to weather forecasting, humans are not well suited to finding context-specific (i.e., personalized) optimal solutions without support. The methodology we present here, model-based forecasting (MBF), a borrowed technology broadly termed data assimilation, is the machinery that makes it possible for personalizing DM2 treatment forging a personalized, glucose/insulin/nutrition based forecast of post-meal, continuous glucose forecast. This methodology through the to personalization of mechanistic models that allow for nutrition-based post-meal glucose forecasts, creates a concrete step between a nutrition choice and variables correlated with long-term health, high glucose and HA1C. While difficulties remain, the data assimilation methodology will form the computational foundation for personalized application-based DM2 interventions such as mobile applications that DM2 patients use for making meal choices and for managing and observing their overall health.

Methods
We prospectively collected 21 days of nutrition, glucose, and HA1C data from patients in a DM2 intervention study. We then selected two mechanistic endocrine models, a relatively simple an ultradian model developed to model fast glucose-insulin dynamics in healthy individuals and a complex meal model developed as a detailed model of meal-time metabolism as related to glucose-insulin dynamics for both individuals who were either healthy or had DM2. Both models can take glucose, insulin, and nutrition as input variables and can forecast glucose, insulin, and between 30 and 70 other physiologic parameters. To integrate an individual’s data, personalize the models through parameter training, and generate a forecast, we embedded the models in a dual unscented Kalman filter (UKF), a DA methodology used to optimize and forecast nonlinear processes. Using the patient data we then created glucose and nutrition based post-meal glucose and insulin forecasts for both models. To evaluate which model performed better we use both pointwise predictive density of the model forecast compared to measurement and KL divergence between the distribution of glucose measurements and forecasts.

Results
After the initial training of 20-30 meals, both models personalized via convergence to the individual patient and both models forecast post-meal glucose well. The ultradian model minimized the point-wise predictive error and therefore provided a better immediate post-meal forecast. In contrast, the meal model minimized the KL divergence between kernel density estimate of the measured glucose and forecast glucose densities, implying that the meal model provided a better representation of glucose representation of the patient in general, while not providing as optimal of an immediate post-meal glucose forecast.

Discussion
The MBF-based methods, even with limited training, can provide accurate, personalized, nutrition-based glucose. The hope is that MBF methodology will be used to personalize nutrition-based, post-meal glucose forecasts, allowing individuals with DM2 to make personalized, informed nutrition choices based on immediate, concrete meal-dependent glucose forecasts combined with an understanding of how glucose levels and dynamics affect health. Nevertheless, serious questions remain. While both models personalized to the individual, they provide different “optimal” knowledge. The meal model yielded a better overall picture of glucose dynamics while the ultradian model provided a better immediate post-meal glucose forecasts. We do not know which type of knowledge would be more useful for patients to make meal choices and manage their DM2. Given the 10’s of mechanistic glucose models available we must evaluate which model will be of greatest potential impact. But, to choose an evaluation metric we must understand what information about future glucose dynamics, when provided to a patient, will yield the best self-care-based outcome.

Increase in Prescriber Error Rates Following Implementation of Computerized Physician Order Entry

Gretchen B. Alexander, M.D., Gilbert M. Ramos, M.A., Maricopa Integrated Health System, Phoenix, AZ

Background
A critical impetus for the adoption of computerized physician order entry (CPOE) systems has been the anticipated improvement in patient safety through reduction in medication errors. A number of studies have demonstrated an association between CPOE adoption and decreased medication errors [1]. However, improved outcomes with respect to patient mortality and morbidity have not been as clearly described. Other work has shown unexpected consequences of CPOE including increases in physician cognitive workload [2] as well as increases in new types of medication errors [3]. It has been hypothesized that CPOE with clinical decision support (CDS) would reduce prescriber errors, but few studies have specifically examined the effect of CPOE adoption on prescriber error rates.

Purposes
To evaluate the effects of a commercial computerized physician order entry (CPOE) system on the rate of medication errors in a public hospital, and to compare errors by type and degree of patient harm prior to and following CPOE implementation.

Methods
A retrospective longitudinal review of data from the hospital’s Quality and Risk database (MIDAS) was performed. Error rates were collected and evaluated for a 36 month timeframe; 14 months before CPOE implementation (pre) and 22 months following CPOE implementation (post). Percentages were calculated for all error types (source of error) and categories (degree of associated harm). Comparisons were performed with Student’s T or Chi squared analysis, as appropriate. Statistical significance was defined as p<0.05 for all calculations.

Results
A total of 2644 errors were self-reported during the study timeframe. Overall, self-reported error rates did not change statistically following CPOE implementation (1295 pre and 1349 post). However, individual error classes did show statistical change with increases in some error types and decreases in others. Significant increases in prescriber errors and errors associated with a higher level of patient harm (Type D and E errors) were observed.

Errors in the following categories showed a statistically significant increase pre to post:
Category A (8.3% pre and 31.6% post; p<0.0001)
Category D + E errors (3.32% pre and 5.71% post; p<0.05)
Administering (43% pre and 47.7% post; p=0.03)
Prescriber error (5.3% pre and 15.3% post; p<0.0001)

Conclusions
While error rates may also be affected by other factors, computerized physician order entry adoption in a public hospital appeared to be associated with increases in certain types of medication errors. The unintended consequence of increased prescriber errors suggests continued need for research on best practices for: consideration of clinician workflow during system development; physician training and support during and after CPOE implementation, and physician involvement in ongoing system optimization.

Identifying Home Care Clinical Practices Most Associated with Hospital Readmissions and Non-Admitted ER Visit Rates: Secondary Data Analysis

Dari A. AlHuwail, MSc, Güneş A. Koru, PhD
1University of Maryland, Baltimore County, Baltimore, Maryland, USA

Introduction
Utilization outcomes, particularly, the (i) hospital readmission rates and (ii) non-admitted ER visit rates have become a subject of growing interest in recent years due to cost concerns [1][2]. Arguably, as the health-care processes of home health agencies (HHAs) improve, their monitored utilization outcomes should improve as well [3]. However, due to limited resources, many HHAs need to apply focused and prioritized process improvement initiatives [4]. To support such initiatives, this study identified the home care practices most associated with higher utilization rates.

Methods
This research followed a secondary data analytics approach. Sixteen process variables about adherence with clinical practices and two utilization outcome measures, all represented as rates, were obtained from 2014 Medicare Home Health Compare (MHHC) Database. The data set included approximately 10,000 observations, each corresponding to a single HHA. To control for socioeconomic status and ruralness, two surrogate measures, Median Household Income and Rural-Urban Commuting Area (RUCA) were attached to each observation based on the HHA’s zipcode. RUCA was coded as an ordinal variable, which increased with ruralness. RUCA and Median Income were obtained from University of Washington and University of Michigan, respectively. Regression trees were developed using a computationally intensive process facilitated by the “rpart” package in the statistical environment, R. Two types of regression trees were developed by taking (i) hospital readmission rate and the (ii) non-admitted ER visit rate as the response variables. For both types of models, the predictors consisted of the process variables, median income, and RUCA.

Results
Interestingly, RUCA explained the utilization variance most in all models. Both utilization outcomes were worse for HHAs serving in rural areas. This finding shows that including RUCA as a control was appropriate. Median Income became relevant only when RUCA was not included. For hospital readmissions, the following three clinical practices, listed in the decreasing order of explaining variance, were most important: (1) How often the home health team checked patients’ risk of falling, (2) How often the home health team began their patients’ care in a timely manner, and (3) With diabetes, how often the home health team got doctor’s orders, gave foot care, and taught patients about foot care. For non-admitted ER visits, a similarly ordered list of top-three clinical practices was (a) checking for fall risks, (b) treating patients for pain, and (c) starting care in a timely manner.

Informatics Perspective
Investments made for Home Health Compare database seem to be useful for supporting reproducible research. While advanced computational tools are readily available today, collection and integration of quality data from multiple sources at the desired level of granularity seem to be the major challenges in the near future. From an organizational process improvement perspective, such integration through the development of Health IT tools can inform HHAs to improve clinical quality, safety, and patient outcomes.

Conclusions
A smaller number of clinical home care practices were most associated with two important utilization outcomes. Checking for fall risks and timeliness, also important practices for patient safety were associated with both hospital readmissions and ER visits. These results should be immediately useful to HHAs in their focused and prioritized process improvement efforts.

**DECISION ANALYSIS FOR OROPHARYNGEAL CANCER IN RADIOTHERAPY**

Ahmad K. Aljadaan¹, John H. Gennari¹, Mark H. Phillips², and Wade P. Smith²

¹Department of Biomedical Informatics and Medical Education; ²Department of Radiation Oncology, University of Washington, Seattle, WA

**Abstract:**
In radiation oncology, for some populations of patients, there is uncertainty about cure rates for a given level of radiation. Because the dose-response curve is not precisely understood, one cannot predict exactly how different prescription doses might affect outcomes. Our goal is to understand where the decision points are: When does more information change clinical practice?

**Background:** In radiation oncology, there is sometimes insufficient data relating treatment dose levels to patient utility. The National Comprehensive Cancer Network provides clinical practice guidelines, but the optimal dose level (number of greys of radiation) is still sometimes unclear, especially for specific sub-populations of patients. Ideally, different dose levels would be associated with different cure rates, but the shape of this dose-response curve is not fully known. Our goal is to apply decision analysis to support both decision making and potentially the design of future clinical trials, so that better, more evidence-based decisions can be made about prescription dose levels for specific patients.

In Oropharyngeal cancer, side effects such as xerostomia (dryness of mouth) and dysphagia (difficulty swallowing) often occur as a result of the radiotherapy treatment with the standard dose level. These side effects are severe and can induce life-long social and emotional burdens. A larger dose can increase the probability of disease control but also increase the probability of side effects. Recently, studies found that Human Papillomavirus positive (HPV+) populations of oropharyngeal cancer patients have a higher survival rate after therapy. Current randomized controlled trials are exploring the reduction of radiation dose to minimize side effects for HPV+ patients. Treatment de-escalation for these patients is also being explored through a less-toxic systemic therapy (Cetuximab) as an alternative to standard chemotherapy.

**Methods:** We built a decision model incorporating an Influence Diagram and a Markov Model for outcomes for reduced treatment in oropharyngeal cancer. The Influence Diagram calculates probabilities of outcomes which are used in a Markov cohort simulation in order to calculate Quality-adjusted Life Years (QALYs) of patients undergoing radiation therapy and systemic therapy. In order to change clinical practice the QALYs for reduced therapy must be higher than for standard therapy. We also performed sensitivity analysis to determine the robustness of the model for certain parameters. In Fig. 1, we show four different curves representing different assumptions about the rate of cure per increasing radiation dose (as % change per Gray).

**Impact:** Our goal is to delineate which outcomes of clinical trials would lead to changes in clinical practice, and to use Value of Information analysis to identify which model parameters are most crucial to decision making. This type of model has broad applicability to other disease sites in radiotherapy and to clinical trials in medicine in general.

**Figure 1.** Preliminary Results for Expected Utility after Radiotherapy for HPV+ late stage (III/IV) Oropharyngeal Cancer. The Utility decreases as the disease control rates fall, and increases as toxicity rates fall.
Medications and Events Most Commonly Discussed in Facebook and Twitter

Introduction
As social media rises in popularity and in use as a communications tool, pharmaceutical industry and regulatory agencies alike are working to see how social listening (the process of identifying and assessing what is being said about a company, individual, product or brand in social media) can be used to augment the current data sources for pharmacovigilance (active monitoring of drug safety). In working towards better patient safety regarding drugs and other pharmaceutical products such as vaccines, we set out to determine what information is available through social listening that might help determine best practices for use of these data.

Methods
All publicly available English language posts in Facebook and Twitter from November 2012 to February 2015 which mentioned a pharmaceutical product (medication, vaccine, or consumer healthcare product) and at least one symptom that resembled an adverse event as tagged by an automated classifier system (“Proto-AE”) were obtained and de-identified by third-party vendor Epidemico™. Post content was acquired through public application programming interfaces (APIs, the Twitter Public API, e.g.) and data provisioning services (e.g. DataSift). Post text was tokenized and tokens identified by Natural Language Processing (NLP) methods. Based on identified tokens, products and symptoms were associated with each post. Each product name was mapped to standard Anatomical Therapeutic Chemical (ATC) classifications, and each Proto-AE was mapped from vernacular language to MedDRA terminology using a custom dictionary developed for Epidemico’s MedWatcher Social™ platform. The products and symptoms were then counted and summarized by export into a spreadsheet.

Results
A total of 862 products were mentioned in the context of a possible adverse event over the time period of collection, with 1,411,705 total Proto-AEs among them. Many posts paired more than one symptom with a product, allowing for 6,796,179 total MedDRA PT symptoms coded among 751 individual PTs.

The most common products by ATC Level 1 (listed along with most common products within the class) were: Nervous system (narcotics and acetaminophen, ADHD, psychiatric, antiepileptics), 749,292 Proto-AEs (53%); Respiratory system (antihistamines, inhalers, antitussives including hydrocodone/codeine), 245,485 (17%); Antiinfectives for systemic use (vaccines, anti-influenza, antibiotics), 204,556 (14%); Musculoskeletal system (NSAIDs, botox, muscle relaxants), 52,822 (4%); and systemic hormonal preparations (corticosteroids, thyroid hormones) 35,448 (3%).

The most common Proto-AE symptoms by System Organ Class (SOC) in the MedDRA hierarchy (listed along with top three PTs in class) were: General disorders and administration site conditions (pain, malaise, drug ineffective), 2,070,364 (30%); Nervous system disorders (headache, altered state of consciousness, memory impairment), 1,169,018 (17%); Psychiatric disorders (depression, anxiety, insomnia), 1,150,096 (17%); Respiratory, thoracic, and mediastinal disorders (asthma, dyspnea, oropharyngeal pain), 333,702 (5%); and Injury, poisoning, and procedural complications (overdose, injury, incorrect dose), 315,361 (5%).

Conclusion
Social listening provides a large number of Proto-AE reports even when limited to just these two popular social media sites and the English language. In looking at the use of the social listening and considering how it may best augment current pharmacovigilance practices, it is important to consider that the top five therapeutic classes and Proto-AE symptoms account for 91% and 74% of overall posts, respectively. Overall, social listening offers the potential to supplement existing pharmacovigilance practices. More research is needed to understand the broad applicability of this emerging capability.
Enhancing Use of the Problem List in the Inpatient Setting

Charles H Andrus MHA 1, Kevin O’Bryan MD2, Phillip Asaro MD 2, Stanley Paul Hmiel MD PhD2, Feliciano Yu MD MSPH 2
1St. Louis Children’s Hospital, St. Louis MO, and 2Washington University School of Medicine, St. Louis MO

Introduction

Problem lists management modules have become standard in electronic health records (EHRs). Despite this, many clinicians find these modules to be of limited utility because of inability of the system and ontology used to meet the needs of clinicians. Problems lists need to provide utility through being accurate, complete, and non-redundant to meet the needs of clinicians.1

St. Louis Children’s Hospital has a best of breed environment where our inpatient care is primarily performed using a separated EHR from outpatient care. The EHR vendor provided problem list design was initially rolled out with minimal modification but usage was extremely low and as electronic documentation increased, the need to enhance problem list management grew. An approach was undertaken to enhance the user interface and functionality of the problem list management module. International Medical Objects (IMO) ontology was selected as the ontology for the problem list and heavy clinician engagement was used to redesign a user interface.

A Novel User Interface

The user interface was redesigned to employ a graphic user interface with the ability to drag and drop problems and have “quick buttons” to perform common actions such as resolving a problem or evolving a problem from a generic problem such as fever to a specific problem later in the clinical course such as pneumonia. In addition, we wanted to ensure that accurate problem lists were sent out at the end of visits to provide continuity of care on an outpatient basis and to ensure the patient’s chart would be as accurate as possible in preparation for a future visit. This was accomplished by a similar user interface where users would create discharge diagnoses and chronic problems from the current problem list. Users are forced to address all acute issues as either resolved, discharge diagnosis, and/or chronic diagnosis. Once submitting this, users are presented with a preview of what the patient’s problem list will look like at the next visit and the ability to edit this as needed to ensure that future visit information is accurate.

Adding Problems through Search Tools

The second major change we made was to enhance the ability of the system to support users looking for specific problems. IMO’s ontology is designed to contain a complete list of problems in clinician friendly terms with synonyms for any terminology a clinician might be likely to use. While this is successful when clinicians search for very specific terms, generic terms produce long lists of results that are difficult for a clinician to review and select an appropriate term. As a result clinicians select relatively generic terms. Initially we managed this by providing an alternative list of the top 15 problems other clinicians had selected while using similar search terms. This improved user satisfaction, but did not lead to the use of more specific terms; rather it augmented poor term selection.

To resolve this issue, we developed a new search algorithm. In this algorithm, the computer counts frequency of each word in all of the search results. Terms present in >95% of results or <5% of results are excluded. Certain common words are also eliminated. The computer then presents these terms in order of decreasing frequency to the user as possible filters for the user to use. The user can use these terms as include or exclude filters with one click. Using this functionality clinicians rapidly narrow from hundreds of terms to typically 2-4 terms with 2-3 clicks. Additionally, users learn terminology for future searches and include these terms in their initial search in the future.

Conclusion

Since implementation of these solutions, we have seen enhanced usage of the problem list and user acceptance. The average visit now has 6 (±6.13) problems, rather than the previous 3 (±3.03).

Feasibility and Acceptability of an Online Maternity Education Platform

Adriana Arcia, PhD, RN1, Deren Bader, CPM, DrPH2, Eva Rose Asaan Warner, BA1
1Columbia University, New York, NY; 2Maternity Neighborhood, Charlottesville, VA

Background and Significance
There exist stark racial, ethnic, and socioeconomic disparities in US childbirth outcomes.1 Uptake of prenatal care, abstinence from substance use, adequate intake of folic acid, and weight gain within recommended guidelines are among the behaviors promoted by Healthy People 2020 because they are known to improve birth outcomes.2 Women at greatest risk for poor outcomes because of social factors also are more likely to have low health literacy and thus be disadvantaged in their ability to receive and interpret health messages that promote healthy self-management.3 However, health literacy is not solely a function of individuals. Health literate organizations “include populations served in the design, implementation, and evaluation of health information and services” and “meet the needs of populations with a range of health literacy skills while avoiding stigmatization.”4 Therefore, a health literate maternity information system prioritizes identifying and meeting the unique needs of the women most at risk for poor outcomes.

The Maternity Neighborhood™ (MN) Care Guide™ is a mobile-ready, web-based patient education platform populated with curated, evidenced-based, multi-media content for maternity care. Content is automatically delivered week-by-week based on gestational age. Secure messaging is an integral part of the platform in that it enables communication about content between the pregnant woman and her care team, thus promoting engagement with care. The goal of the research in progress described here is to insure that Care Guide™ (known as Maternity Information Access Point or MIAP for research purposes) is a health literate resource for at-risk women. To that end, the aim of this study is to explore the feasibility and acceptability of an online maternity education platform among Medicaid-enrolled women. The theoretical framework is Coiera’s common ground theory of healthcare communication which posits that “for computational tools to be of value, they have to share ground with human beings. Users need to know how to use the system and the system needs to be fashioned to users’ needs.”

Focus Group & Field-Testing Protocol: We will recruit 24-32 pregnant (aged 18+, ≤35 weeks’ gestation) Medicaid-enrolled women via community-based doula groups to engage in pairs of focus groups bookending a one-month at-home MIAP field-testing period. Initial group topics are: 1) barriers to/facilitators of Internet access; 2) Internet use, including social networking, for maternity information; 3) preferred forms of maternity information access; 4) online platform acceptability; and 5) desired attributes of platform content. During field-testing, participants will be encouraged to meet information needs with MIAP and engage with the research team through secure messaging. In follow-up groups, usability and satisfaction will be evaluated qualitatively and with items modified from the Unified Theory of Acceptance and Use of Technology (UTAUT2). Content analysis will be used to analyze qualitative data.

Discussion
Findings will be used to identify opportunities for facilitating Internet access for Medicaid-enrolled women within a prenatal services context (e.g., subsidies for data plans) and to configure a health literate platform that meets the needs of the target population. Planned future work will evaluate the impact of platform usage on clinical outcomes.

A Smartphone-based Gait Assessment System for the Elderly

Naoya. Arisaka, Msc¹, Kosuke. Mizuno, PhD², Noritaka. Mamorita, PhD¹, Yoshitaka. Shiba, PhD³, Harukazu. Tsuruta, PhD¹

³Department of Physical Therapy, Kitasato University, Sagamihara, Japan

Introduction

The kinematic assessment of posture and movement in walking plays on important role in rehabilitation for the elderly and in the assessment of prosthetic replacement arthroplasty. However, the quantitative evaluation of the posture and movement usually requires expensive and large-scale apparatus such as the 3-dimensional position analyzer and therefore is limited to laboratory settings. To solve this problem, we developed a smartphone-based system which measures and analyzes the motion in walking using the built-in sensors and communication via Bluetooth Low Energy.

Methods

The system is composed of measuring devices and a control device. The application is developed using Objective-C and we used iPod touch (Apple Inc., USA) in this study. To verify the accuracy of our system, optical data were gathered simultaneously using an optoelectronic motion capture system. Using the developed motion measurement system, we measured and evaluated the posture of sixty elderly people and fifty patients with Parkinson's disease periodically. The tilt angles of the trunk and pelvis were measured by two iPod touches which were synchronized with each other. This study was approved by the Ethics Committee of Kitasato University Hospital and all participants provided their informed consent to participation.

Results

The control device can order start/stop of the measurement to measuring devices simultaneously (Figure 1) and both devices can display the summarized results in addition to the observed changes of the three-axis posture angle and acceleration in a graphical manner (Figure 2). The observed data were automatically uploaded to the server. We compared the posture angle in walking between the older (71.1 ± 5.1 years, old (mean±SD), n = 44) and the younger (21.3 ± 1.0, n = 30) women. The trunk of older women was significantly tilted forward, pelvis was significantly tilted backward, and the left-right movement of the pelvis was greater than the younger women.

Conclusion

We developed a smart-phone based motion measurement and analysis system. The results suggested that we can use our system instead of the expensive optoelectronic motion capture system. The difference of observed posture angle between our system and the optoelectronic system was less than 2.3 degree¹. We are now collecting data of 110 subjects including patients with disabilities at four hospitals to obtain reference values for the rehabilitation of the elderly. The measuring device will be used as a stand-alone measuring tool that the elderly can use at home.

Introduction

Computerized Clinical Reminders (CCRs) play an integral role within the Computerized Patient Record System (CPRS), the Veterans Health Administration’s Electronic Medical Record (EMR). CCRs encompass clinical documentation and administrative tasks for improving quality of care and safety while adhering to institutional guidelines[1]. Our study aims to objectively assess the burden of CCR work during clinic visits at the VA San Diego.

Materials and Methods

We recorded clinical workflow using an eye tracker, a video camera, and usability software installed on the physician’s computer to record the physician’s gaze, their computer screen, and mouse activity. We subsequently tagged click sequences manually in order to connect them to reminder activity. Qualitative data about CPRS use and CCRs was collected through interviews. We grouped the named CCRs and rank ordered them by frequency and time-at-task. We selected 2 reminders (Tobacco cessation and Medication reconciliation) for task analysis. Video review and content analysis was performed manually. Physician gaze activity was analyzed and displayed graphically as gaze paths and heat maps using proprietary eye tracking software.

Results

We analyzed CCR activity data for n=89 outpatient visits (Fig) with 16 physicians (9 primary care and 7 specialists). 148 reminders completions, (Median=0, IQR=[0-3]), all PCPs, were concentrated in 37 visits (Median=4, IQR=[2,6]). 21% physicians reported they work on reminders after the visit (post work). We also analyzed CCR activity for new versus established patients. We found 29 distinct types of CCRs and the most frequent 3 were medication reconciliation, HIV screening, and colorectal cancer screening. The average time to complete a reminder was under 1 minute. Qualitatively, physician interviews indicate burdensome and unnatural CCR workflow is associated with: perceived time pressure, redundant documentation (“see notes” in reminder text box and auto-appended reminder template text in notes), and blocking states in the EMR (inability to search for information with reminders open).

Conclusion

Based on observations of CCR activity, time-at-task is small relative to the length of visit. However, in other metrics, CCR burden is reflected by physician’s perception of time pressure attributed to CCR work, which appears to arise from unoptimized clinical documentation system and CCRs. Redesign of reminder functionality and revision of content could improve the usability of CCRs for physicians.

Evaluation of a Self-Triage Decision Aid System in Pregnancy-Induced Hypertension and Diabetes Mellitus: Preliminary Results of a Randomized Control Trial

Azam Aslani, PhD1, Fatemeh Tara, MD2, Leila Galichi, PhD3, Sina Madani, MD, PhD4, Ameen Abu-Hanna, PhD5, Saeid Eslami, PhD1,5

1Department of Medical Informatics, Mashhad University of Medical Sciences, Mashhad, Iran; 1Department of gynecology, Mashhad University of Medical Sciences, Mashhad, Iran; 2Mental Health Research Center, Iran University of Medical Sciences, Tehran, Iran; 3The University of Texas Health Science Center at Houston, School of Biomedical Informatics, Houston, TX, USA; 4Department of Medical Informatics, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Abstract
It has been shown that access to health information can benefit patients by helping them making a more knowledgeable decision in the clinical care process. Computerized decision aids can be used to facilitate such decisions. We investigated the effect of a self-triage decision aid tool on enabling pregnant women to monitor the development of gestational hypertension and diabetes mellitus and actively participate in their health care process.

Introduction
Acquisition of reliable and actionable health knowledge can help patients actively participate in their care process and make more effective decisions about medical interventions. Published reports in Iran showed that two important causes of maternal death are the lack of awareness of alarming symptoms during pregnancy and ignoring recommendations from the health care providers. Pregnancy-induced hypertension (PIH) is the cause of death in 17% of reported cases. It has also been shown that gestational diabetes mellitus (GDM) can cause macrosomia and very low blood glucose levels in newborns. We anticipated that pregnant women can quickly identify the alarming symptoms and prevent high-risk situations by using a self-triage computerized decision aid (CDA) tool. The objective of this study was to evaluate the effect of a self-triage decision aid system on pregnant women in managing PIH and GDM during pregnancy.

Methods
Randomly selected pregnant women between the ages of 16 and 38 were recruited in a randomized control study. They were examined by six gynecologists in two publicly funded maternity health service centres and by two other gynecologists in private offices between December 2013 and June 2014. The unit of randomization was the gynecologist. Both the intervention and the control groups received the conventional care while CDA was used only by the intervention group. We mainly measured self-efficacy by self-efficacy scale, knowledge by 15 multiple choice questionnaire and anxiety by Spielberg state anxiety inventory. The authors who designed the questionnaires assessed CDA utility, ease and frequency of use.

Results
All 116 participating pregnant women (56 in intervention group and 60 in control group) completed their pre and post pregnancy evaluations. There was no significant difference between the two groups in terms of their age, gestational age, number of previous pregnancies and birth, and planned pregnancy. Improvement in the reported feel of self-efficacy in the intervention group for PIH and GDM were 15% and 11.2% respectively (both with p=0.001). Additionally, gaining of knowledge about PIH and GDM in the intervention group, compared to the control group, was significantly higher (p=0.001). According to the reported lab values, there were no differences in blood pressure and glucose levels between the two groups. Three cases of emergency childbirth due to PIH were reported in the control group versus one in the intervention group. Ninety three percent of the pregnant women who used CDA reported quicker identification of the alarming symptoms. Use of the CDA did not cause an increase in the anxiety level in the intervention group (before: 42.5±9.4 p=0.8, after: 42.2±9.2 p=0.9) compared to the control group (before: 42.1±11.3 p=0.8, after: 42.5±11.3 p=0.9).

Conclusion
CDAs could potentially improve self-efficacy and knowledge of pregnant women about their health status. As more ambulatory care settings migrate from hospitals to community care centers, informatics tools such as self-triage CDAs, can play an important role in such transitions.

Automating Identification of OEF/OIF Veterans Diagnosed with ALS

Jennifer M. Aucoin, MD, MPH1, Shon G. Michael, MD1, Amy C. Justice, MD, MSCE, PhD1,2, Perry L. Miller, MD, PhD1,2, Cynthia A. Brandt, MD, MPH1,2, Huned S. Patwa, MD1,3
1Connecticut VA Health Care System, West Haven, Connecticut, USA; 2Yale Center for Medical Informatics, New Haven, CT, USA; 3Yale University School of Medicine, New Haven, CT, USA

Introduction
Amyotrophic lateral sclerosis (ALS) is a progressive, fatal disease involving rapid degeneration and death of motor neurons. Family history, increasing age, and male gender are known risk factors for ALS, but numerous other factors have also been proposed1, including Persian Gulf military deployment2,3. This study endeavors to look at the feasibility of automating the identification of ALS patients in the Veterans Administration electronic record in order to allow for accurate measurement during an ALS-care quality improvement initiative.

Methods
The study sample consisted of a cohort of Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) veterans in the Connecticut VA health system electronic medical record. Charts were queried for any existence of the ICD-9 code for ALS. The resulting charts were reviewed by a neurologist to confirm the diagnosis of ALS and to see whether the criteria established by the U.S. Agency for Toxic Substances and Disease Registry (ATSDR)4 were met.

Results
The results of chart review by a neurologist are shown in Table 1. Over 20 percent of charts containing the ICD-9 code were found to contain no apparent diagnosis of ALS. The majority appeared to be instances of miscoding, and only two of the patients met the ATSDR criteria.

Table 1. Classification of patients with at least one ICD-9 code of ALS (335.20).

<table>
<thead>
<tr>

<td>2.0%</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>Identified as duplicate</td>
<td>0.7%</td>
<td>1</td>
<td>NA</td>
</tr>
</tbody>
</table>

Conclusion
Previous attempts to identify veterans with ALS for inclusion in an ALS database have shown that ICD-9 code alone is insufficient criteria for confirming the diagnosis2. The criteria established by the ATSDR are reasonably accurate in identifying patients with a diagnosis of ALS. Patients who met criteria but were found not to have ALS were both prescribed Riluzole in response to previous prescription by outside providers.

Combining indirect and direct methods to enhance research of online health communities

Uba Backonja, PhD RN¹, Albert Park, PhD¹, Andrea Hartzler, PhD²,
Megan N. Taylor, BS¹, Troy Griffith, BS¹, Wanda Pratt, PhD¹
¹University of Washington, Seattle, WA; ²Group Health Research Institute, Seattle, WA

Abstract

Although online health communities offer opportunities to characterize members’ communication and needs, researchers often use only indirect methods, limiting their inquiry. We discuss how our study combined indirect text processing and direct interviews with individuals who had cancer experience. Our approach allowed us to gain rich insights for the design of online communities that may not have been gained through indirect methods alone.

Introduction

When studying online health communities, researchers typically use indirect methods like online surveys¹ or large-scale text processing of existing posts², which have many benefits. Online surveys can be inexpensive and reach many people regardless of geography or time constraints. Analyzing existing data can be inexpensive and achieved in large volumes. Although these indirect methods unveil what individuals do in online health communities, they may not reveal a deeper understanding of how and why they engage in these communities. Also indirect methods may not reach non-users or members who do not contribute. Adding direct methods of inquiry, such as interviews, could overcome these limitations by providing nuanced information about members’ perceptions or behavioral motivations. This information can be invaluable when improving online health communities.

Utilizing both indirect and direct methods in online cancer community research

To understand how and why those with cancer experiences could use an online health community profile to select peer mentors, we conducted a study using online posts (indirect) and in-person interviews (direct). After receiving approval from our institutional review board, we automatically processed posts from an existing online cancer community to populate key elements of mentor profiles. We created paper mockups of profiles that described health interests and characteristics of potential mentors. Next we recruited patients and caregivers with cancer experience via fliers and cancer support groups. We conducted in-person interviews to gain an understanding of how and why participants preferred certain mentor profiles as they sorted and ranked profiles. Interviewers used open-ended questions to guide discussion and allow participants to converse freely and tell stories, providing contextual and emotional information to support ranking preferences. Participants thought out loud and took notes on paper mockups to elicit insights into their decision-making behind rankings. By combining direct and indirect methods in this online health community research, we had many opportunities to learn about individuals’ perceived challenges and benefits of joining online health communities and reasoning behind information they sought in profiles.

Conclusion

Using indirect and direct methods in online health community research provides nuanced understandings not typically obtained only via indirect methods. Interviews revealed informational and emotional decision-making of how and why participants chose mentors. Text processing allowed us to create profile mockups, providing realistic interview prompts. This information is important—it links to cancer patients’ online behavior³ but may be missed using indirect methods. Using indirect and direct methods provides invaluable insights about what, how, and why users engage with online health communities, which carry rich implications for online health community research.

Learning Useful Abstractions from the Web

Abhishek Bafna(abafna@umich.edu)  Jenna Wiens(wiensj@umich.edu)

The successful application of machine learning to electronic medical records typically turns on the construction of an appropriate feature vector. Defining abstractions to create high-level, low-dimensional feature vectors can help in identifying clinically meaningful similarities among patients especially when the number of training examples is limited. In this work, we compare conventional unsupervised dimensionality reduction techniques (e.g., principal component analysis (PCA)) to new approaches that leverage a large corpus of freely available expert knowledge in unstructured form from the Web. As a case study, we consider the task of learning useful abstractions for patient medications.

We begin with a list of \( d \) medications and retrieve a corpus of text documents from Wikipedia, where each document corresponds to a medication. Next, we apply latent Dirichlet allocation (LDA) to this corpus [1]. This results in a representation where each medication (i.e., document) is associated with a distribution over \( k \) topics (\( k < d \)). One can think of the learned topics as classes of drugs, allowing the identification of similar drugs based on the topic distribution.

Given a cohort of patients and their medication orders, we propose a method for representing each patient in a \( k \) dimensional feature space and for computing a patient similarity/kernel matrix. We employ the earth mover’s distance (EMD) when building the matrix [2]. In contrast to the Euclidean distance, the EMD allows one to incorporate the underlying distances between topics.

Table 1: The area under the receiver operating characteristic curve (and the inter-quartile ranges) for the test set when 3% of the total training data (i.e., 500 samples) are used.

</tr>
</tbody>
</table>

Assuming patients with similar outcomes receive similar medications, an improvement in our ability to identify similar medications should translate to an improvement in our ability to identify similar patients. Thus, through a series of experiments, we measure the utility of the learned abstractions by considering three different clinical classification tasks: mortality within 30 days of discharge, readmission to the hospital and ICU after discharge and readmission to the ICU during the same hospital visit. We consider over 25,000 patient admissions from the MIMICII database [3]. After minimal preprocessing, we identified 2,285 “unique” medications. Applying the methods described above, we first mapped each medication to a vector of 60 topics. Next, we learned an EMD-kernel SVM classifier, for each outcome. In our experiments, we repeatedly divided the data by into training and test sets (70/30 split). We also varied the percentage of training data used from 1% to 100%. In addition to the proposed approach LDA+EMD, we considered three additional approaches for comparison:

- \( d \)-Categories - each patient is represented in the original \( d \)-dimensional feature space,
- PCA - uses principal component analysis and a kernel based on the Euclidean distance, and
- LDA - uses LDA analysis and a kernel based on the Euclidean distance.

Figure 1 shows the resulting test performance for the third task (ICU readmission). We note that when the number of training examples is limited (e.g., < 10%) the LDA+EMD model outperforms the three baselines. Table 1 displays similar trends for the other two prediction tasks. These results, support the hypothesis that one can learn useful abstractions efficiently by leveraging the large quantity of unstructured medical knowledge available on the Web.

Data Error Transparency in Health Information Exchange
Gina B. Baker, MSN1, Shan He, PhD1, Darren K. Mann1 Pallavi Ranade-Kharkar, MS1, 2, Sidney N. Thornton, PhD1, 2
1Intermountain Healthcare, Salt Lake City, UT; 2University of Utah, Salt Lake City, UT

Abstract
Health Information Exchange (HIE) systems complicate the current electronic medical record (EMR) structure and may perpetuate data errors as information is passed between healthcare providers. The longitudinal compilation of clinical data including the incorporation of inbound HIE data can form a baseline from which quality deviations can be assessed. Select types of data variability can be characterized and scored by logical processing. Alerting patients and providers to these possible errors in their EMR could potentially lead to decrease in adverse events and may improve data quality of transmitted clinical information.

Introduction
Data errors exist in the patient record even with EMR use. Several studies have documented the monetary and safety consequences of these errors; one study cites medication error rates as high as 37%1,2. Data errors of all types are likely to occur at transitions of care such as discharge to home or transfer to another hospital2. HIE systems are facilitating the information needs at transitions of care but may also inadvertently propagate the data errors. Some data errors are not detected until after they are transmitted to an external organization or a patient-facing interface. Weir and Nebeker suggest that these data errors lead to a lack of trust in the facility EMR3. Organizational risk and reputation may suffer when the data errors are detected outside the disclosing organization. Intermountain Healthcare developed screening rules for detecting data errors from externally acquired data sources including HIE data transmissions. Similar rules apply for outbound data to identify possible errors for the outside consumer.

Methods
Outbound data was evaluated for obvious and contextual errors specific to the patient or their encounter. Evaluation of the patient encounter was necessary in some areas to evaluate for patient-specific data such as body mass index. Obvious errors included limit checks for type mismatch, insufficient attribution for the data model or physiological incompatibility. A scoring system based on accuracy, completeness and clinical context was introduced to categorize the seriousness of the data error. Certain categories of data can be suppressed or filtered from the outgoing data package. For example, rules may be configured to filter aged or irrelevant data. Other data types may be flagged with cautionary guidance for future reconciliation workflows. Contextual or higher scoring data in question can be prioritized for review by the receiving provider or patient through their respective workflow tools.

Results and Discussion
Evaluation of the patient specific data from longitudinal patient record can help determine data that might be inconsistent or in conflict. Guidance and severity scoring can help alert the patient or provider receiving the data for the need to review and reconcile, thus improving the accuracy of the medical record. Feedback may be provided to local clinical and quality departments for systematic improvement.

Conclusions
Clinical data moving between organizations can be scrutinized and scored for integrity. Automated and select manual workflows can be enabled to control data quality. Metadata for data quality concerns can be shared among organizations and can improve the community view of a patient record. Transparency into data quality may translate into improved patient care with reduced treatment errors, and may increase patient engagement.

Patient-Centered Postoperative Wound Surveillance Using Smartphone Digital Photographs
Kate L. Baker, MA¹; Andrea N. Mahnke, MS¹; Sara Fernandes-Taylor, PhD²; Jason T. Wiseman, MD²; K. Craig Kent, MD²
¹Marshfield Clinic Research Foundation Biomedical Informatics Research Center, Marshfield, WI
²Department of Surgery, University of Wisconsin-Madison, Madison, WI

Background
Surgical site infection (SSI) is the most common nosocomial infection in surgical patients and accounts for 38% of post-operative complications¹. If diagnosed at an early stage, SSI can be treated in the outpatient setting with oral antibiotics and wound care, precluding the need for readmission, intravenous antibiotics, and reintervention. Patients rarely recognize early stage wound infections and often require intensive treatment and rehospitalization². It also produces increased health care costs and is the leading cause of unplanned, potentially preventable hospital readmissions for surgical patients³. Although interventions have been designed and employed to prevent SSI, the focus has been on the surgical procedure itself and the immediate postoperative inpatient stay¹. A large proportion of wound infections, however, develop following hospital discharge and prior to routine follow-up¹. The fact that SSI develops or progresses in the outpatient setting makes transitional care coordination an important focus in the effective management of SSI. Patient-centered technological interventions to improve transitional care for surgical patients are necessary to stem the burden of SSI and readmissions.

Objective
We designed and tested a patient-centered, outpatient wound surveillance program using smartphone digital photography to promote early recognition of SSI following discharge with the goals of (1) empowering patients to partner with their surgeons in monitoring their SSI symptoms and overall postoperative recovery, (2) diagnosing SSI at an early stage, enabling outpatient management, and (3) preventing hospital readmission and the serious morbidity and mortality associated with wound complications. We focused on vascular surgery because of the high risk of SSI and readmission among these patients.

Methods
We designed a patient-centered smartphone app that enables patients to transmit wound photos and symptom information to the vascular service. Images are uploaded to the PACScan image system, permitting side-by-side review of chronological images with linkage to the medical record. In collaboration with geriatricians and community/patient research advisors, we designed a patient-centered training process to teach patients or caregivers to take and transmit photos of their wound using smartphones. We conducted focus groups with community/patient research advisors to assess ease of use of the app and effectiveness of the training process. We utilized print and picture based teaching materials, “teach-back” by the patients, and pre-discharge reinforcement with a test photo transmission. We undertook formal usability testing of the app on an inpatient vascular surgery service to evaluate (1) barriers to participation, (2) patient experience, (3) picture and information quality, and (4) successful information transmission and assimilation into PACScan. Screen and audio recordings were captured during the inpatient usability testing for analysis and identification of usability issues. Improvements were recommended and implemented iteratively.

Results & Conclusions
Data collection and analysis pending.

Integrating Conceptual Models to Inform the Design of a Family Health Information Management System for Hispanic Dementia Caregivers

Suzanne Bakken, PhD, RN,1,2 Maribel R. Granja MPH, 1 Niurka Suero-Tejeda, MS, MA, CHES,1 Samantha B. Stonbraker, MPH, RN,1 Robert J. Lucero, PhD, MPH, RN3,4
1School of Nursing and 2Dept of Biomedical Informatics, Columbia University, New York, NY 3College of Nursing, University of Florida, Gainesville, FL 4VA HSR&D Center of Innovation on Disability and Rehabilitation Research, Gainesville, FL

Introduction

Little is known about the information and communication needs of family caregivers for Hispanics with dementia or the manner in which online tools may meet those needs. As part of the New York City Hispanic Dementia Caregiver Research Program (NHiRP), we are developing a Family Health Information Management System (FHIMS) through participatory design methods with caregivers. The purpose of this poster is to describe the development of a coding framework for the initial participatory design sessions.

Methods

We conducted 21 participatory designs (10 English and 11 Spanish) with a total of 28 participants. Audiotapes of the sessions were transcribed and coded in the language of the session. The goal of the qualitative data analysis was to understand the dimensions of caregiving as well as the information and communication needs of those who care for persons with dementia as a foundation for designing the FHIMS. To create a coding framework for the analysis, we integrated concepts from Coiera’s1 model of the communication task-information task continuum with a clinical adaptation2 of the Krikelas model of supplemental information seeking behavior.

Results

The coding framework includes five top-level concepts: Caregiver, Patient, Information Needs/Tasks, Communication Needs/Tasks, and Online Tools. Key concepts from Coiera that informed the coding framework were information task, communication task, information agents, communication agents, and common ground. The concepts of patient information, domain information, and logistical information were used to further define information needs and tasks. In terms of common ground, communication needs/tasks were categorized by those in the conversation with an assumption of variation in amount of common ground, e.g., caregiver to caregiver vs. caregiver to healthcare professional.

Conclusions

The integration of concepts form several models resulted in a coding framework that is being applied to inform the design of the FHIMS.

Analysis of Workflows: How Workflows Interact with CPOE to Contribute to Errors

Eleanor J. Barone, MD¹, Anne Miller, PhD²

Vanderbilt University Department of Biomedical Informatics, Nashville, Tennessee¹
Center for Research and Innovation in Systems Safety (CRISS), Vanderbilt University Medical Center, Nashville, Tennessee²

Introduction

The introduction of electronic health records (EHR) and computer provider order entry (CPOE) have decreased medication errors but at the cost of disrupting workflows.¹ This project explored the possible reasons for wrong order errors by investigating the interaction between workflows and CPOE at a major medical center, and how those interactions may contribute to or mitigate wrong order errors.

Method

Vanderbilt University Medical Center implemented its in-house CPOE in 1994. From 7/25/13 to 7/25/14, Quality Management identified 9 incidents involving wrong patient orders with CPOE as a potential contributing factor. A human factors investigation was requested and a three stage investigation implemented: Stage 1 - researchers interviewed quality analysts regarding original findings; Stage 2 - we observed 6 residents and 3 attending physicians in the Emergency Department (ED); 4 residents and 2 attending physicians in the Medical Intensive Care Unit (MICU), and 2 attending physicians on the Hospitalist Service. During the observations, the providers were asked to explain what they were doing as they did it. Observations were recorded on paper. Stage 3 – Data was analyzed using the Functional Resonance Analysis Method (FRAM)² to model and interpret the observations. The FRAM models work functions as defined by their inputs and outputs, and as mediated by time, regulatory process, and resources. FRAM supports explorations of ‘why things go right or wrong’ and is helpful for identifying adaptive redundancies as well as vulnerabilities in sociotechnical systems.

Results

Stage 1: Based upon analyst interviews, two of the wrong orders were same last name errors. CPOE was the only common factor for all of the errors. Eight errors were variations on a patient receiving the wrong test or medication. A radiology report read into the wrong patient chart was the most benign error.

Stage 2: User interface design issues were observed to contribute to error by making patient identification difficult and error prone. Order set popup screens, for example, obscured patient identifying information, inconsistent patient identifier placement reduced cross-checking, and the use of medical record numbers to select patients enhanced the risk of wrong patient selection. In all settings, ED, MICU, and Hospitalist Service, redundant communication and checks between staff on each patient order, plan, and result were critical to minimizing the risk of wrong patient orders.

Stage 3: FRAM modeling showed different communication and information flow pathways in each setting. In the MICU, bedside team rounding supported patient identification and enhanced cross checks and follow-ups. Hospitalists in small interdisciplinary teams functioned as sole entry points and so closed information and feedback loops. The ED, however, relied heavily on each provider’s individual sense of responsibility for the patient’s outcome with very limited interdisciplinary communication or cross checking. Additionally, ED ordering tended to be a ‘ballistic’ process; once sent, erroneous orders were difficult to identify and information flow loops could not always be closed.

Discussion

No one solution is evident. Wrong patient orders are particularly insidious as they involve two victims (the patient who did and the patient who did not receive a needed order). The prominent display of patient information, including patient photographs may better support order cross-checking, but it may not identify patients not receiving orders. Association between orders and problem/diagnosis lists may help providers in assessing order appropriateness, and support wrong order identification earlier. However, social processes that enhance team work, communication and cross-checking enhance resilience overall.

Visualization of Clinical Decision Support Failures

Mujeeb Basit, MD\textsuperscript{1,3}, Adam Wright, PhD\textsuperscript{2,3,4}
\textsuperscript{1}Beth Israel Deaconess Medical Center, Boston, \textsuperscript{2}Brigham and Women’s Hospital, Boston, MA
\textsuperscript{3}Harvard Medical School, Boston, MA, \textsuperscript{4}Partners HealthCare, Boston

**Introduction:** Evidence suggests that CDS can improve health care quality, safety, and effectiveness (1). Prior work has demonstrated multiple failures and potential harm from CDS improperly executing (2). Visualization of this complex data may help CDS implementers identify potential malfunctions of CDS rules. The visualization complements automatic methods for detecting CDS failures and identifying the key characteristics of failure. Visualizing temporal data can be complicated by natural variations in daily rates, including holidays, periodicity (weekends and seasons) and secular trends

**Methods:** We extracted CDS rule firing data from the EHR used at Brigham and Women’s Hospital, and visualized the data using the ggplot2 R package. Two rules “CAD and no ASA” and “Adult Seasonal Influenza” were selected for demonstration. Firing rates were adjusted for visit volume (using notes written as a proxy).

**Results:** Figure 1 shows the preliminary and final versions of the date visualization in a calendar format. The visualization clearly displays two known malfunctions in the CAD/ASA alert the first from 2009 being a system-wide spike caused by a system update and the second from 2012 caused by a corruption of the drug class manager resulting in excessive execution. The third graph shows the seasonal data and changes over the years. Each year the start and magnitude of the execution has changed. There were no anomalies noted in this data.

The enrichment of the circular graph focused on seasonal information.

**Discussion:** CDS implementation and monitoring is critical in maintaining patient safety and clinical trust. There exist multiple potential causes of failures of these systems. Clinicians have come to depend on these systems therefore identification of failures is critical. Visualization of this complex dataset is helpful to identify the pattern of failure and facilitate with correction. In future work, we plan to expand our system to optimize for variation in seasonal trends and provide linkage to a real-time dashboard for detecting anomalies before they lead to widespread patient harm.

**Figure 1:** Firing rate of “CAD and no ASA” alert at BWH over a five-year period demonstrated with various filters and the final version with annotation and enrichment. The third panel shows fire rate for “Adult Seasonal Influenza” alert demonstrating complexity of seasonal data.

A Faceted-Search Mobile App
for Matching Cancer Patients to Targeted Therapy Clinical Trials

Thomas P. Bechtold, M.B.A.1, Elly J. Cohen, Ph.D.2, Susan L. Colen2,
Laura J. Esserman, M.D., M.B.A.2
1QuantumLeap Healthcare Collaborative, San Francisco, CA; 2UCSF Department of Surgery,
San Francisco, CA

Introduction

Difficulties in patient recruitment often delay timely completion of cancer clinical trials. This can be even more challenging for targeted therapy trials where eligibility is restricted to patients who have tumors with a specific molecular signature. Since most patients who participate in trials do so at the suggestion of their providers, the availability of an easy-to-use mobile app that matches patients to trials by tumor stage and biomarker status could facilitate recruitment at the point-of-care. This is consistent with the growing use of healthcare apps by providers for decision support and patient communication during the clinical encounter1.

The Problem: Finding Clinical Trials at the Point-of-Care

Most clinical trials search tools are web-based and use either keyword searches or lengthy questionnaires. Keyword searches require the user to know a suitable keyword, and yield significant false-positive results. Questionnaire-based searches impose the up-front burden of entering a detailed health history. Furthermore, these resources do not perform accurate and up-to-date matching based on biomarker status.

Our Solution: Faceted Search with Biomarkers

We have developed a new service (CTMatch, ClinicalTrialsMatch.org) that finds cancer clinical trials with faceted search. Faceted search has been demonstrated to improve complex searching, especially with dynamic taxonomies. CTMatch prompts the user with facets specific to their indication. Given the proliferation of targeted therapy trials, it features accurate matching to biomarker test results, made possible by an innovative and scalable curation tool (Table 1, Figure 1). For example, a breast cancer patient seeking a trial will be prompted for breast-specific biomarkers ER and HER2/neu. The taxonomy - demographics, cancer stage and biomarker status – was chosen for its discriminative power.

Table 1. Biomarkers used in CTMatch faceted search

<table>
<thead>
<tr>

<td>B-RAF</td>
</tr>
<tr>
<td>Estrogen/Progesterone Receptors</td>
<td>BRCA1</td>
</tr>
<tr>
<td>HER2/neu Receptor</td>
<td>BRCA2</td>
</tr>
</tbody>
</table>

This matching service is distributed as Apple and Android mobile apps. It can also be inserted on a web page or accessed as a web service from clinical decision support applications.

Figure 1. Percentage of US cancer trials (n=3865) with eligibility criteria involving biomarker status

Evaluation

Usability testing will validate the efficacy of the app.

Conclusion

CTMatch is a new mobile app that uses a faceted search design, including stage and biomarker status, to find cancer clinical trials. In the future, the ability to capture and track critical care elements at the point of care will enable true automation of trial matching, making CTMatch even more convenient and integral to care.

Social Network Analysis: Data Collection Challenges and Solutions

Marge Benham-Hutchins, PhD, RN¹
Barbara Brewer, PhD, RN, FAAN²

¹University of Texas, Austin, TX ²University of Arizona, Tucson, AZ

Patient safety and quality initiatives have emphasized the importance of health information technology (HIT) design that supports communication and collaboration between providers across the continuum of care. Health organization decision makers, researchers, and designers of HIT have recognized compatibility issues between HIT and multi-professional communication processes resulting in problems integrating HIT into existing provider workflow. These problems have been associated with new types of medical error that are influenced or caused by HIT. Solutions depend on a closer examination of how providers access information and communicate with other providers in the provision of collaborative patient care. This has led to an interest in Social Network Analysis research methods.

Network analysis methods acknowledge that social networks are composed of individuals and the relationships between them. These relationships can be analyzed based on specific characteristics (e.g., frequency or quality of communication). In the complex health care environment relationships between providers may or may not be reciprocated, and individual providers can be connected to more than one other person or group. Social Network Analysis methods have been used successfully to explore the impact of information technology on provider communication ¹, to examine communication in emergency departments ², to identify information exchange networks in the ICU ³, and to describe medication advice-seeking in a renal unit ⁴.

 Nonetheless, designing and implementing a methodologically sound Social Network Analysis data collection process in the healthcare environment has proven to be challenging for both new and experienced researchers. This poster will provide preliminary results from a systematic review of the literature that examines common challenges and solutions associated with collecting network analysis data in the health care environment. Preliminary information on data collection methods, issues and solutions from the author’s ongoing longitudinal network analysis study will be included.

Using the Adverse Event Reporting System: Can Analysis be Streamlined by Text Processing?
Andrea Benin, MD1,2, Samah Jamal Fodeh, PhD1, Michele Koss, RN2, Kyle Lee2, Perry Miller, MD, PhD1, Cynthia Brandt, MD MPH1

(1) Yale University School of Medicine, Yale University, New Haven, CT, 06520
(2) Connecticut Children’s Medical Center, Hartford, CT, 06106

Background: Existing, widely used, software systems for reporting adverse events are limited in how they handle the unstructured text entered by frontline staff. This limitation means that use of this potentially rich information depends on extensive manual sorting and collation of electronic data, which is resource-intensive and prone to variable results.

Aim: The aim of this study was to develop an electronic approach to processing the text in medical event-reports that is reliable enough so that it can be used to improve patient-safety in a less manually resource-intensive fashion.

Methods: We categorized event-reports from February 2012-January 2014 at our free-standing children’s hospital using 3 different approaches: (1) manual review by experienced clinicians (“reference standard”), (2) rule-based query, and (3) semi-supervised machine learning: a hybrid method that combines F-score feature selection with Laplacian support vector machine. The 2 computerized approaches were compared to the “reference standard” and to the “usual approach” (categorization by the frontline personnel in the vendor-software tool). We focused on 5 use cases that were chosen specifically for their daily importance to patient-safety; 3 were known to be near impossible to identify using only the vendor-based query-tool. Being able to electronically identify the reports relevant for these chosen use cases is meaningful for improving patient-safety. All 9164 reports were annotated for the 3 use cases that were not readily amenable to direct query using the vendor-tool and “usual approach.” A subset (437) of the event-reports was also annotated for the 2 use cases that are part of standard taxonomies and known to be readily able to be queried using the vendor-tool and the “usual approach.”

Results: Both electronic approaches perform better than the “usual approach” and well enough to be used in practical applications to improve patient-safety.

<table>

</tr>
</tbody>
</table>

Conclusions: Electronic approaches to streamlining the use of free-text entered into an adverse event report system are feasible and can be extremely valuable in categorizing and sorting this important data for use in improving patient-safety. In addition, the common taxonomy used by this widespread software vendor does not readily support accessing all aspects of the information that is needed to improve clinical care; alternate, automatable query-methods offer important flexibility to the users of this data hoping to improve patient-safety.
Demographic Factors Associated with Differences between New York Inpatient Medicare Charges and Payments for (DRG 065) Stroke

Barbara A. Berkovich, MA, E. Shannon Stearman, BA, Craig W. Johnson, PhD
The University of Texas Health Science Center at Houston (UTHealth)
School of Biomedical Informatics, Houston, Texas

Introduction
Stroke results in morbidity and mortality and is costly to treat. Hospital costs have exceeded Medicare reimbursements for ischemic stroke. In 2007, additional levels for complication and comorbidity were added to the Diagnosis Related Groups (DRGs) of the Centers for Medicare Services (CMS) to establish diagnosis-based payments. Research to establish predictable cost drivers for hospitalizations continues. Using IRS New York State 2012 tax returns, we determined whether differences between Medicare charges and payments for DRG 065 (intracranial hemorrhage or cerebral infarction with a major complication or comorbidity) were associated with rural versus urban locations, total income, and unemployed households, as determined by zip code.

Methodology
Dataset 1 included all New York State records for hospital-specific charges per discharge using the Medicare Severity Diagnosis Related Group (MS-DRG) for Fiscal Years 2011 and 2012. Dataset 2 is from the IRS website Statistics of Income Tax Stats –Historic Table 2, which is a record of tax returns (Form 1040) from the IRS Individual Master File system from January 1, 2013 to December 31, 2013. We analyzed data from 91 urban and 25 rural providers in 103 unique zip codes. For each zip code, we integrated charges and payments from Dataset 1 with Dataset 2’s amount of income tax, number receiving unemployment, and whether farm income was reported. The latter three variables operationalized total income, unemployed households, and rural versus urban locations, respectively. We eliminated four New York State zip codes (10802, 11794, 13503, 14642) due to missing data. Due to unequal sample sizes and a nonnormal distribution, parametric and nonparametric (using Puri-Sen L statistic) univariate analyses of covariance employed SPSS 22 UNIANOVA to compare Medicare charge versus payment differences for rural and urban locations. Total income and unemployed households served as covariates.

Results and Conclusion
Rural versus urban locations (L = 10.02, p = .005; F = 8.50, p = .004) and total amount of tax (L = 12.85, p = .001; F = 11.82, p = .004) were significantly related to the Medicare charge versus payment difference. Urban location covariate-adjusted Medicare charge versus payment difference was $8,411.37 higher than rural, primarily attributable to $10,745.37 higher average charges in urban locations (Figure 1). Unemployed households were not statistically significant. Across all zip codes, and independent of urban versus rural location, the charge versus payment difference increased as a 1% (p = .001) multiple of the amount of tax. In other words, the wealthier the zip code the greater the charge versus payment difference.

GeneLab: NASA’s Open Access, Collaborative Platform for Systems Biology and Space Medicine

Daniel C. Berrios, MD MPH PhD1,2, Terri G. Thompson, PhD2, Homer W. Fogle, MS2, Jon C. Rask, MS2, Joseph C. Coughlan, PhD2
1University of California, Santa Cruz, CA; 2NASA Ames Research Center, Moffett Field, CA

Purpose

NASA’s mission includes furthering our understanding of biological systems through space-based research in order to improve life on earth and to enable the human exploration of space. To achieve these goals, NASA is investing in GeneLab1 (http://genelab.nasa.gov/), a multi-year effort to maximize utilization of the limited resources to conduct biological and medical research in space, principally aboard the International Space Station (ISS). Through the GeneLab project, researchers will include ground-based high-throughput genomic, transcriptomic, proteomic or other “omics” analyses as part of their experiments conducted on the ISS. The data from these analyses will be stored in the GeneLab Data Systems (GLDS), an information system currently being developed for the project. GeneLab intends to support “open science” research on the housed data sets, creating a multiplier effect on the science return from these experiments; the GLDS will serve all omics data without restrictions to the public. The system will ultimately include a biocomputation platform with collaborative science capabilities, to enable the discovery and validation of molecular networks that are influenced by space conditions.

Design

NASA has chosen a phased capability implementation for the GLDS. The initial phase of the GLDS development effort emphasizes capabilities for the submission, curation, search, and retrieval of omics data sets. Important design considerations have included 1) leveraging existing systems and systems components to deploy Phase 1 capabilities expediently; 2) determination of optimal data set curation procedures including metadata representation and generation and quality control procedures; and 3) balancing GLDS accessibility with user engagement and usage tracking capabilities. Phase 2 will focus on interoperability and supporting federation of GLDS-housed data sets with externally-curated data in data set search, retrieval, and annotation functions. In Phase 3 we will develop a platform for computational biologists to execute and collaboratively develop analysis tools, integrate results of analyses with those of collaborating researchers, annotate data sets with interpretations, and share insights and hypotheses, building a knowledge base relevant to space biology and medicine.

Challenges

The GeneLab project and the GLDS face several challenges, including:

- Numerous and rapidly evolving standards for omics data, metadata, protocols and analyses
- Representing the unique aspects of space biology experiments as metadata and related data
- Coalescing access to a wide range of biocomputation tools, overcoming lack of interoperability
- Incentivizing engagement by the space biology/medicine research community

Conclusion

High-throughput systems for analyzing genomes and transcriptomes are generating vast amounts of biological data. Integrated analyses of these data with proteomic, metabolomic, physiologic, and phenotypic information holds the promise of rapid elucidation of complex molecular pathways, and of huge advancements in biological understanding and space medicine. Data Systems like the nascent GLDS are challenged with the representation, organization and integration of these highly complex data sets, and with providing researchers with the tools and environments they require for maximum utilization of the data in their analyses.

Introduction

Electronic health records (EHRs) have emerged as a promising tool to improve health care quality. Significant federal investments are being made to encourage EHR adoption through incentive programs, however nursing homes (NHs) are excluded from these initiatives. Facing substantial barriers to EHR adoption, NHs appear to be lagging behind in EHR adoption rates, compared to other health care settings. However, research systematically assessing rates of EHR adoption in NHs on a national level is lacking. To that end, this study aimed to assess EHR adoption in a national sample of NHs.

Methods

As part of a larger mixed methods study (R01NR013687) to explore infection control and prevention in NHs, cross-sectional 34-item surveys were conducted in a randomized national sample of NHs. Questions were included in the survey to assess whether EHRs had been implemented in the NHs and what year. Additionally, one question asked about tools and resources used in the facility to help make clinical decisions, including clinical decision support systems (CDSS). Descriptive analyses were performed using the SAS 9.3 statistical software.

Results

Completed surveys were received from 990 NHs. Half of participating NHs (51%) reported having implemented EHRs. Of those, 76% had implemented EHRs in 2010 or later, and 35% in 2013 or later. Only 11% of the NHs where EHRs had been implemented reported that CDSS was used in the facility to help make clinical decisions.

Conclusion

The findings of this study indicate that EHRs are still a relatively new phenomenon in NHs and adoption still lags behind acute and primary care settings. More work is needed to increase adoption. Furthermore, to achieve meaningful use, health care settings are required to implement CDSS but in this study only 11% of NHs using EHRs reported using such systems. Future research should go beyond examining adoption rates to assessing the level of implementation and use of EHRs in NHs.

An Ontology-Driven Patient History Questionnaire System

Jonathan P. Bona, Ph.D., Gunther Kohn, B.S., Alan Ruttenberg, M.S.
University at Buffalo School of Dental Medicine, Buffalo, NY,

Our group at the University at Buffalo School of Dental Medicine is developing an ontology-driven system for collecting, recording, and managing patient history data. It consists of an HTML5-based web application backed by an RDF triple store database. The triple store is populated with explicit representations, in the Web Ontology Language (OWL), of patients and the entities - disorders, diagnoses, activities - that medical histories are about. The underlying ontology also directly represents the processes involved in collecting and recording this data, and the questions, answers, and other information artifacts involved. It links those artifacts to the entities in the world that they are about.

This standalone system interoperates with our clinic information management system, Picasso, as part of a pilot project to test the usefulness and effectiveness of the ontology-based approach. It replaces a series of paper questionnaires that are currently used to perform initial assessment of patients, and to gather both general history as well as oral and dental health history. Though it will be used initially in our dental clinics and include oral health questions along with general health history, the design is domain independent and driven by flexible ontology-based models. The underlying ontology will be publicly available for others to use and extend in similar projects.

As a dental school, our mission includes not just patient care but also education and research. This system is intended to support all parts of that mission. It is designed to collect and store patient history data in a way that preserves its meaning independent of any one use. By using explicit ontology-structured representations, we represent information about the patient's history independently of how it was produced (i.e., the particular user interface and business logic that currently make up different levels of the software). By representing that data natively in OWL and storing it in a triple store that supports reasoning, we make that data immediately available to logical inference and for authorized users and connected information systems to query using SPARQL.

We make extensive reuse of existing science-based ontologies associated with the OBO Foundry. These include the Ontology of Biomedical Investigations (OBI), the Information Artifact Ontology (IAO), the Ontology for General Medical Science (OGMS), and the Oral Health and Disease Ontology (OHD). Each of these includes terms relevant to our task that have clear English definitions, computable logical definitions, and links to a shared upper-level ontology, Basic Formal Ontology (BFO).

The system is designed for ease of use. Rather than just recreating a paper questionnaire in software as a list of questions, we have included the ability to dynamically adjust which questions are shown based on answers to previous questions. The use of explicit representations of information artifacts makes it straightforward to model dependencies and other relations between questions and answers, and to use those to dynamically adjust the display.

Another of our goals is to completely capture provenance of any data that the system records. We explicitly represent the question-taking process, its participants (patients, clinicians), its sub-processes (asking questions), and its outputs (information artifacts about the patient’s health history). Every answer is linked to terms that identify the individual that recorded the answer, the exact time at which it was recorded, the patient who has this answer as part of their history, and so on. In our clinics, the person taking and recording a patient history is often a student working under the supervision of a faculty member who must formally approve the student's work at the end. This information - approval status of a history-taking session, identify of the approver, etc - is also captured.

A patient has one history that is made up of many statements about the patient's health, which are often recorded at different times, possibly in many different sessions of history-taking. Our system preserves the complete patient history over time. By default, a provider viewing or editing a patient's history sees only the latest answer to each question, but a provider in an authorized role may view the complete history for a particular question or group of questions, or even a snapshot of the complete history as it was at a particular time.

In conclusion: we are developing a medical history application based on a carefully constructed ontological model that represents not only the things that a patient history is about, but also elements of the history-taking process, including the questionnaire and its contents. The result is a flexible, easily queried knowledge base of patient histories with semantic representations that facilitate its use for research and in conjunction with other information systems.
AMIA 2015 POSTER SUBMISSION

TITLE: Development and implementation of a Floor Admit Reevaluation Alert (FARA) in a large academic emergency department.

AUTHORS:
- James Booth, MD, MSHI, University of Alabama at Birmingham
- Eta S. Berner, Ed.D, FACMI, University of Alabama at Birmingham
- Jorge Alsip, MD, University of Alabama at Birmingham

DESCRIPTION OF THE PROBLEM:
The severity of a patient’s illness determines whether a patient is admitted to a normal hospital floor bed or a higher acuity ICU bed. Emergency physicians are often the providers responsible for determining the severity of a patient’s illness and the patient’s admission order. The emergency department (ED) is a fast-paced error-prone environment and the severity of a patient’s illness may go unrecognized, resulting in a severely ill patient being admitted to a normal floor bed. This type of error is associated with increased mortality and increased rate of ICU transfers from the floor.

We sought to develop a clinical decision support (CDS) pop-up alert that informs emergency physicians, at the time of the admission order, of any significant vital sign abnormalities or lab abnormalities that are associated with increased severity of illness. By alerting the physician to dangerous vital sign and lab abnormalities, we hope to decrease the rate of severely ill patients being inappropriately admitted to a floor bed instead of an ICU bed. After a thorough literature review, it appears that this type of CDS alert is a new concept and we found little evidence that this type of CDS alert has been formally researched.

METHODS:
Using a combination of literature review and internal hospital data, we developed a list of 13 vital sign and lab abnormalities associated with increased patient mortality and ICU transfers from the floor. Using these 13 criteria, we developed a CDS pop-up alert that alerts the emergency physician if the physician attempts to admit a patient to a floor bed with one of the 13 criteria present. The alert was implemented at a single large academic medical center and 6 months of pre-implementation and 6 months of post-implementation patient data were collected and analyzed.

RESULTS:
From August 15, 2014 to February 15, 2015, there were 1633 alerts. 155 (9.5%) of the alerts resulted in a change from floor admission to ICU. 87 (5%) of the alerts resulted in a change from floor admission to a step-down unit (a level of acuity between a floor and ICU bed). The total number of ED admissions was 6.7% higher in the 6-month post-implementation period while the total number of ICU transfers from the floor, within the first 12-hours of floor admission, decreased by 4.7%. 16 patients required transfer from the floor to the ICU within 12-hours of their alerts being over-ruled/ignored in the ED.

CONCLUSIONS:
ED physicians use clinical judgment when determining the need for a high-acuity ICU rather than a lower-acuity floor bed when admitting patients to the hospital. Occasionally, ED physicians may not recognize the severity of a patient’s illness and admit a patient to a lower-acuity floor bed where the patient’s status may continue to deteriorate. Design and implementation of a CDS pop-up alert may decrease the rate of severely ill patients admitted to a floor bed instead of an ICU and consequently decrease the rate of ICU transfers from the floor. Future analysis of the 13 alert criteria will be used to further refine the alert to improve the sensitivity or specificity of the alert. Additionally, analysis of ICU transfers post-implementation of the alert will help further refine the criteria.
Integrating Electronic Health Record Competencies into Undergraduate Health Informatics Curricula: A Preliminary Qualitative Study

Elizabeth M. Borycki, RN, PhD¹, Janessa Griffith, MSc¹, Andre W. Kushniruk, MSc, PhD¹

¹University of Victoria, Victoria, British Columbia, Canada

Abstract

Integration of electronic health record (EHR) competency development throughout an undergraduate health informatics program is essential for students to understand how: (a) the EHR can be used by clinicians, (b) to procure an EHR for specific user interface requirements and workflows, (c) to customize a system for local (i.e. health care system and clinical/organizational practice) setting, and (d) to design, develop and build an EHR.

Introduction

Integrating electronic health record (EHR) competencies into a four year undergraduate health informatics (HI) program can be difficult. Understanding what competencies can be integrated at what point in time is critical to students being able to understand the theory used in the design of the technology and how it is used, procured, customized to local settings and designed and developed for use². The development of EHR competencies for those studying HI needs to be considerate of how the technology is created, and how it fits with a local setting. Some of these EHR competencies are specific to developer (vendor) needs (e.g. those surrounding design). Others are specific to large health care organizations, clinics, and physician offices, where the emphasis of knowledge is placed on clinician use of the technology, procurement to fit the local healthcare setting and customization to improve user interface and workflow fit. Educational research in the area of HI has focused on how to technically provide students with access to EHRs in the classroom setting, the barriers to providing access to EHRs, and the impact of introducing the EHR into the classroom upon competency development. In this poster we present on the preliminary findings from a qualitative study investigating how EHRs could be integrated into a four year undergraduate HI program to facilitate student competency development.

Learning Objectives

Learners will be able to formulate a plan to integrate EHR competencies into HI programs and will be able to identify and develop a strategy for integrating vendor and health care organizational EHR competencies.

Methods

We conducted a qualitative study to investigate students’ perceptions about how EHR competencies could be integrated into an undergraduate program. Ten, third and fourth year students, were recruited to participate following completion of a course where they were introduced to EHRs for the purpose of developing competencies. At this point in the HI program third and fourth year students had completed two cooperative education experiences where each student has worked for two to three, four month blocks in an industry setting. Students were interviewed by telephone at a time and place that was convenient for them.

Results and Conclusions

Several key themes emerged. Student competencies could be subdivided into those that are required by vendors and those by health care organizations. Vendor EHR competencies involved the design and development of new EHR features and functions and interfacing technologies (e.g. mobile devices). Health care organizational competencies involved procurement, customization (user interface design, workflow) and implementation competencies. There is a need to integrate EHR competencies into HI programs in a manner that allows for competency development in the first year of study, followed by the development of increasingly more complex competencies such as those related to procurement, customization and implementation of the technology followed by design, development and building of new EHR features and functions and associated technologies.

Technological Education Institute (TEI) of Athens, Athens, Greece

Abstract

It is the aim of this project to describe in brief the work in progress of a Home-care Scheduling, Supervision and Security (HC-SSS) approach, designed to support the continuity of health-care and the secure information management, for patients discharged from Hospital to Home-care.

Introduction

Health-care provision is moving towards home-care that is expected to provide for the upcoming demand, for patient-centered care, reducing at the same time the level of reimbursement for health-care providers.

Methods and Resources

The Scheduling-module allows for any discharging physician to assign, an appropriate set of home-care patients’ activities, provided by attendants, nurses etc. to specific Diagnoses. These activities’ profiles are adaptable and every physician is allowed to set up his own profile, create a new one or modify an existing one, in order to adapt it to each patient’s specific characteristics, needs and demands, on a completely web-enabled modular platform.

The Supervision-module aims to generate personal health-records from home, allowing hospitals, health-care providers and families to track and respond to critical behavioral and clinical patient data. The assigned homecare activities are displayed in the Supervision application in the form of instructions and reminders. Furthermore, the system allows for automatic and manual entry of patients’ parameters that should be monitored, according to homecare plan and it allows for real-time audio-visual communication and/or uploading of any sort of digital data.

The Security-module: A security-web manages all requests that need to be secured, to and from the recipient. The server is implemented using Microsoft ASP.NET Web API 2. The exposed API requires the use of https/SSL in order to allow for the execution of any action. We have created a digital certificate on our IIS Server that the user has to accept and after the acceptance, all calls that are being made are considered secured at the transmission layer. We also use anti-forgery techniques to prevent cross site request forgery (CSRF), like altering the query string on the browser. All sensitive requests contain a hash-value that has to be validated on the post. As an extra level of security, we have enriched our tokens with different "salt"-values on each "logical domain", preventing, thus, an attacker that manages to get hold of a valid token, to use it in another domain of the application. After the security server has successfully received a message, it strips the valid information and gives the control to an application server, which knows how to process the requests. Both servers can be hosted under the same IIS or even be incorporated in a single application.

Results

The system comprises of a home-care scheduling and supervision module, complying with the ASTM E2369 (CCR) and ISO 13606-1:2008 Standards and comprising adequate cryptographic algorithms’ data-protection.

Conclusion

Web-based techniques are ideal for home-care applications, since they allow for numerous distributed users, while reducing the maintenance task to a group of web-servers at the same time.
Reducing Healthcare Costs through Medical Recommendations

Lina Bouayad, PhD1,2, Balaji Padmanabhan, PhD1, Kaushal Chari, PhD1
1University of South Florida, Tampa, FL, 2Center of Innovation on Disability & Rehabilitation Research (CINDRR) James A. Haley Veterans Hospital, Tampa, FL

Abstract
In the US procedure and drug costs are often not visible by physicians, leading to high costs of care. Results of an experiment completed by physicians indicate that presenting alternative procedure recommendations with similar outcomes and lower costs may potentially help reduce overall healthcare costs. Interestingly, time pressure greatly affects the physicians’ use of such recommender systems.

Introduction
Healthcare costs have reached skyrocketing numbers in the US, which is now in the leading place when it comes to healthcare spending. Medical fraud clearly contributes to rising costs. In addition, misuse and underuse of medical procedures also contributes to elevated healthcare costs.

Particular to healthcare prices for the same procedures vary significantly depending on the paying party. In an example reported by the Wall Street Journal, the average charge for a joint-replacement surgery ranged from $5,300 in Ada, Okla., to $223,000 in Monterey Park, California1. It is important to note that providers are typically unaware of healthcare costs. Physicians are able to differentiate identify generic drugs within each drug type. However, they remain unacquainted with exact tests and drug costs1.

What if cost information can be presented to medical providers at the right time? In this work we design a medical recommender system that presents alternative prescription options that are 1) appropriate for the patient being consulted, and 2) are lower in cost compared with the physician’s initial selection. Because of the time involved in evaluating different recommendations (especially in emergency rooms), recommender systems have been either selectively used or completely removed2. Taking time pressure into account may therefore be important if it can increase acceptance of such systems.

Methods
We conducted an experiment involving medical providers in Florida. Any clinician with prescription privileges in Florida was able to participate in the study. All participants were presented different patient cases and asked to select the most appropriate prescription regimen. A between-subjects design was used to test the effect of cost on the use of the recommendations. Participants were placed into two different groups presented with varying recommendation costs. One group of participants was presented a list of all low cost recommendations, while the other group received recommendations of mixed costs. On the other hand, a within-subjects design was used to evaluate the impact of time pressure on the physicians’ influence by time pressure. In half of the cases, the participants were given a time constraint indicating high time pressure. Counterbalancing was used to control for any learning effect that might have occurred. Therefore, high-time pressure scenarios were either presented first or last depending on the group of the participant. Participants were randomly placed into four different groups.

Results
We were to recruit 40 physicians for the experiment. Mixed logistic regression, along with decision trees were used to test the significance of the hypotheses. Analysis results will be presented at the conference.

Conclusion
Recommender systems could be used in the medical domain to present cost information to clinicians, and thereby reduce overall healthcare costs. While designing such systems, our results show that it is also important to take into account the physician’s amount of time pressure experienced.

Variable Importance in Recursive Feature Selection with Random Forests for Mortality Prediction in ICU

Sabri Boughorbel, Rashid Al-Ali

Sidra Medical and Research Center, P.O. Box 26999, Doha, Qatar

Method: Feature selection is a research field in machine learning that investigates methods and algorithms for the selection of the most relevant variables [1]. We propose to combine model-dependent and model-independent (feature-based) variable importances in the feature ranking step. This approach introduces robustness to the feature selection procedure. The algorithm [2] describes the recursive feature selection steps [2]. The feature-based variable importance is obtained by computing the ROC AUC using each variable separately. Hence we can evaluate the importance of each feature for the prediction of ICU mortality. The model-based variable importance is computed using the fitted Random Forests model [3].

Algorithm 1: Feature selection with the modified variable importance.

1. Fit the Random Forests model with all features p
2. Estimate variable importance using proposed variable importance

for Each feature subset $F_i$
do
4. Fit Random Forests with $F_i$ features
5. Estimate model performance
6. Re-rank the features using proposed variable importance
7. Compute the performance profile for all sets $F_i$
8. Select the best variable subset $F_{opt}$

Results: For the validation of the algorithm, we used CinC’12 ICU data described in [4]. For each variable, first-order summary statistics are computed from the time-serie data namely mean, max, median, first and last values. In total 124 features are extracted. Table 1 shows the top selected features for the usual and proposed variable importance. Figure 1 shows performance changes with respect to the number of features.

Table 1: Top 5 selected features and corresponding variable importances (V.I.) based on Random Forests model (left two columns) and the proposed variable importance (right two columns). GSC is Glasgow Coma Score (3-15), Urine is the urine output (mL), BUN is blood urea nitrogen (mg/dL).

Discussion: The proposed modification of the feature selection procedure introduces an external factor to the variable importance computation. This factor has the advantage of stabilizing the feature ranking stage since it becomes less prune to model error and sensitivity to correlated features. The analysis of the theoretical effect of using model dependent and independent variable importance is an interesting research topic to further confirm and generalize the proposed approach.

Developing Intermediary Medication Phenotypes via Metabolomics Biotechnology Using an Electronic Health Record-Linked Biobank

Matthew K. Breitenstein, PhD\textsuperscript{1}, Richard M. Weinshilboum, MD\textsuperscript{1}, Jyotishman Pathak, PhD\textsuperscript{1}, Liewei Wang, MD, PhD\textsuperscript{1}, \textsuperscript{1}Mayo Clinic, Rochester, MN

Introduction and Background

Metformin is the first-line therapy for type 2 diabetes mellitus (T2DM). Emerging evidence implicates the potential repurposing of metformin for cancer prevention and treatment (PLOS One 2013;8(8):e71583). However, the details underlying the molecular mechanism of action for metformin are not fully understood. Specifically, the pharmacodynamics (PD) of metformin, the physiological and biochemical impact of metformin in the body, are not clearly understood (Pharmacogenomics 2014;15(4):529-539), which limit availability of intermediary phenotypes for metformin impact in cancer. We seek to utilize combined electronic health record (EHR) data with a linked biobank and metabolomics biotechnology to elucidate metformin PD and develop intermediary medication expression phenotypes that might enable further research regarding the potential repurposing of metformin for cancer treatment.

Materials and Methods

A cohort of T2DM Mayo Clinic Biobank patients with platelet poor plasma samples was identified using a validated phenotyping algorithm (JAMIA 2012;19(2):212-18). A total of 42 pre-defined metabolites representing the function of key biological processes were selected for metabolomic assays. The final cohort (n=600) submitted for metabolomics analysis had cases (metformin monotherapy exposure on sample date, T2DM) and controls (no metformin exposure on sample date, no T2DM) matched by gender and age. Our preliminary cohort (n=207) contained randomly selected samples that were processed and analyzed at the time of this abstract.

Results

In our preliminary analysis cohort 8 metabolites passed Bonferroni correction in the filter step and were selected for further analysis by a cumulative logit model (Table). These associations represent a preliminary metformin metabolomics expression profile and are the subject of active functional and systems pharmacology research.

Conclusion

Our EHR-linked biobank metabolomics study identified a novel preliminary metabolomic profile of metformin exposure in a T2DM population. The metabolites in this profile have potential to serve as intermediary phenotypes in future research endeavors regarding metformin mechanism and/or repurposing for cancer treatment or prevention and will be further refined in ongoing functional validation. Further, this study represents a novel application of informatics phenotyping in an EHR-linked biobank that retrospectively identified a case-control cohort with utility for drug signature development. Finally, this study highlights the translational power of using EHR-based phenotypes to leverage a biobank to drive clinical and pharmacology discovery in the era of precision medicine.
The Internet: A Source of Near Real Time Infectious Disease Information

Juliana J. Brixey, PhD, MPH, RN¹, Catherine Pepper, MLIS, MPH¹, Jacqueline E. Brixey, MA²

¹University of Texas Health Science Center at Houston, Houston, TX; ²University of Texas at El Paso, El Paso, TX

Abstract
Event-based reporting of infectious diseases is an alternative to indicator-based reporting to identify potential cases and outbreaks. Social media have contributed epidemic intelligence to population health surveillance. A search of the peer-reviewed journal literature and of the Internet yielded a set of social media and web-based tools that have been used in event-based disease surveillance reporting.

Introduction
Primary care and emergency department (ED) clinicians can no longer wait days or weeks for infectious disease surveillance information. Global travel by air, sea, or high-speed rail has made the worldwide dispersal of an infectious disease within a few hours a reality. Public health agencies use both indicator-based and event-based surveillance reporting as accepted methods to establish epidemic intelligence¹. Indicator-based reporting entails the systematic routine collection of structured data from health care organizations, diagnostic laboratories, and health care providers to identify known cases or clusters of disease.¹ The lag time from reporting to data analysis and dissemination of findings has the potential to encumber the promptness in identifying an infectious disease outbreak. In contrast, event-based reporting does not rely exclusively on official sources of information, but is grounded in the rapid capture of information about events and rumors of illness or deaths from unstructured data sources such as the news media, news aggregators, Twitter, Facebook, blogs, online discussions, and Really Simple Syndication (RSS) to detect infectious disease threats.² Additionally, search engines such as Google aggregate search queries to predict flu outbreaks³ and Dengue.⁴ The purpose of this project is to identify Internet websites that disseminate near real time information regarding the outbreak of infectious diseases such as influenza (flu), Ebola, severe acute respiratory syndrome (SARS), cholera, West Nile virus, malaria, Escherichia Coli (E Coli) and measles.

Methods
A retrospective review of peer-reviewed published literature and the Internet using the search terms “sentinel surveillance”, “internet”, “emerging/and infectious disease/s”, “syndromic surveillance”, “real-time disease surveillance”, “infectious disease and social media”, and “crowdsourcing epidemiology”. MeSH terms were used for PubMed searches. Articles and websites were scanned for social media tools that support epidemic intelligence.

Results
These websites were identified as among those providing near real time infectious disease information:
Crowdbreak http://www.crowdbreaks.com/
Dengue Trends http://www.google.org/denguetrends/
Flu near you https://flunearyou.org/home
Flu Trend https://www.google.org/flutrends/us/#US
HealthMap http://www.healthmap.org/en/
ProMED-mail http://promedmail.org/

Conclusion
Due to the large number of search returns, pertinent websites were more easily identified by manual review of peer reviewed literature and the Internet websites. The implications from this study suggests a centralized repository is needed for easy access to the information to reduce or prevent the global spread of infectious diseases. Future research could focus on integration and visualization of event-based reporting found in social media tools.

A Literature Review of Medication-Related Clinical Decision Support

Clare L. Brown, MPharm¹,², Sarah P. Slight, PhD¹,²,³, Andrew K. Husband, PhD¹, Neil Watson, MBA MSc², David W. Bates, MD MSc³,⁴,⁵

¹Durham University, Stockton on Tees, UK, ²Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK, ³Brigham and Women’s Hospital, Boston, MA, USA, ⁴Harvard Medical School, Boston, MA, USA, ⁵Harvard School of Public Health, Boston, MA, USA.

Abstract
Medication-related clinical decision support (CDS) delivers automated guidance and support to clinicians. We reviewed the literature of basic medication-related CDS functionalities, from 2007 to 2014, using a systematic approach and reflected upon the issues pertinent to future development. Advancements, such as improving alert specificity and application of human factors principles during the design and implementation of CDS, are important considerations to improve patient care and reduce alert fatigue.

Introduction
Medication-related CDS delivers automated guidance and support to clinicians at the point of prescribing, through the use of electronic alerts or order sets and templates. Basic CDS represents functionality, which is typically a starting point for healthcare organisations, examples include drug-drug interaction (DDI) checks, drug allergy checks, dosing guidance, duplicate therapy checks and formulary decision support.¹ CDS has been associated with improved patient safety, improved standards of care and reduced healthcare costs.² We reviewed the recent literature of CDS functionality and reflected upon the issues pertinent to its future development.

Methods
We searched for papers in Medline (Ovid) and Embase (Ovid), using a systematic approach. We included various MeSH terms and key words such as ‘clinical decision support’, ‘electronic prescribing’, ‘computerized physician order entry’ and terms relevant to the five basic CDS functionalities with a date range of 2007 to 2014. We included all publication types, all types of order entry system and all clinical settings. Only English language papers were selected for further review. Titles and abstracts were initially screened, followed by the full text. Reference lists, papers from world leading experts and the ‘other citing articles’ function were also used to identify additional relevant articles. One reviewer performed screening of papers and data extraction.

Results
A total of 896 articles were identified, of which 184 were considered relevant. The success of CDS depends on users finding alerts valuable and acting on the information received. Including more patient-specific parameters to improve alert sensitivity and specificity (i.e. the ability to detect actual errors and the perceived relevance of alerts), and application of human factors design principles is important across all domains. Assigning a severity level to DDI alerts has been shown to improve alert acceptance. Maintenance of accurate records and cross-sensitivity checks are key to the production of appropriate drug-allergy checks. Patient specific parameters should be utilised to improve the relevance of drug-dosage support; furthermore, suggested doses should be appropriately rounded to facilitate administration. How the CDS system is configured is important for the identification of significant drug-duplication errors. The knowledge base(s) for drug-formulary alerts must be accurate and reviewed regularly in order to produce relevant alerts and encourage formulary adherence.

Conclusions
CDS is still undergoing development. The implementation of automation in healthcare has surged in recent years and this is likely to continue. Human-factors design principles and improving alert specificity are important and future research should contribute to this area. Such advancements are important for system developers during the design stage and for end-users of the system who require better functionality and usability to improve patient care and reduce the likelihood of alert fatigue.

Developing an Ontology from HIV-associated Elements in Research

William Brown III, DrPH, MA\textsuperscript{1,2}, Chunhua Weng, PhD\textsuperscript{1}, David K. Vawdrey, PhD\textsuperscript{1,3}, Alex Carballo-Diéguez, PhD\textsuperscript{2}, Suzanne Bakken, PhD\textsuperscript{1,4}

\textsuperscript{1}Department of Biomedical Informatics, Columbia University, New York, NY; \textsuperscript{2}HIV Center for Clinical and Behavioral Studies, NY State Psychiatric Institute & Columbia University, New York, NY; \textsuperscript{3}New York-Presbyterian Hospital Value Institute, New York, NY; \textsuperscript{4}School of Nursing, Columbia University, New York, NY

Introduction
In 2012 NIH launched the Big Data to Knowledge (BD2K) initiative to address the lack of appropriate big data tools for translational impact. Two main challenges highlighted by BD2K are “standardizing data and metadata”, and “developing new methods for analyzing & integrating biomedical data”\textsuperscript{1}. Integration of diverse HIV-associated datasets was identified as a research priority\textsuperscript{2}. Integrating biomedical data can increase the breadth of variables and statistical power for analysis; in turn improve knowledge and the effectiveness of interventions. Data harmonization is fundamental to integration, and domain-specific semantic harmonization tools are ideal for managing both the diversity of HIV data elements (DEs) and quickly evolving nature of the HIV research domain. Thus, our aims are to 1) screen HIV DEs and identify common data elements (CDEs), and 2) leverage empirical methods and existing knowledge bases to develop and evaluate an ontology to formally represent CDEs in HIV research.

Methods
We collected the information that describes all data elements in nine HIV-associated studies. Using guidelines from the NIH CDE Resource Portal, we referenced DEs across both empirical and knowledge resources to identify their common data elements (CDEs). Empirical methods included: identification of HIV-associated CDEs by reviewing the research literature, and screening DEs from HIV-associated research data dictionaries, based on NIH criteria. UMLS knowledge resources used included: AIDSinfo HIV/AIDS Glossary and AIDSinfo drug database, as well as CDE from LOINC \(>71,000\) measures, SNOMED \(>311,000\) diseases/measures/medications, and RxNorm [medications]. Protégé was used to construct the ontology.

Results
The HIV-associated Entities in Research Ontology (HERO) comprises 91 HIV-associated CDEs from the research literature, over 850 AIDSinfo HIV/AIDS Glossary terms, and 398 HIV-related drugs from the AIDSinfo drug database. HERO also includes HIV-associated DEs from nine research data dictionaries, as well as formalisms, relationships, and inherited hierarchies from HIV-related CDEs in LOINC, SNOMED, and RxNorm. Results from our final evaluation will include: 1) The amount(s) of different sources that could be mapped to the CDE, 2) The percentage of integrated and non-integrated data from each, and 3) An explication of metadata types.

Conclusion
The next phase includes: identification of overlapping CDEs across knowledge resources, and annotation of multiple CDEs’ source origin(s) and associated formalism(s); concept relationship establishment; and intrinsic and extrinsic evaluation of the ontology for completeness and correctness.

Introduction
Retrospective use of clinical data covers a wide variety of investigations including data exploration, quality assessment, and generation and retrospective validation of hypotheses. While clinicians have the domain knowledge to formulate and test hypotheses, they are limited by the unavailability of user-friendly and intuitive tools giving easy access to collected data. The filtering of datasets to select relevant cohorts of patients is often time-consuming and requires a lot of manual steps and/or advanced informatics skills (e.g. scripting, querying). To streamline the process of filtering datasets, we developed a flexible solution that enables to efficiently and intuitively build cohorts with desired characteristics, perform basic analyses, and export the cohorts to be used in advanced analyses.

The Cohort Selection Application
Our application provides two mechanisms of interaction between the clinical user and the underlying data repositories. Predefined filters can be used for building complex cohorts by clinical users without any need for informatics knowledge. For the power-users (e.g. bioinformaticians) we provide the option to define cohorts by advanced scripting and by directly sending queries to the data repository. Figure 1 shows the two alternatives for building cohorts, by using pre-defined filters and by scripting, for the selection of all triple-negative breast cancer patients in the dataset. By relying on widely-adopted ontologies (e.g. SNOMED-CT) we also incorporate reasoning in the process of building filters and enable users to explore the concepts available in each dataset and their hierarchies, make use of synonyms, etc. Advanced functionality allowing the splitting and merging of defined filter stacks is also implemented. To facilitate collaboration we provide functionality for sharing both the filter-stacks and the corresponding cohorts among teams of clinical users.

Figure 1. Selection of a cohort of triple-negative BC patients by scripting (power-users) and with pre-defined filters
Musculoskeletal Flowsheet Data Modeling for Clinical Research

Matthew D. Byrne, PhD¹, RN; Steven G. Johnson, MS²; Beverly Christie, DNP, RN³; Jung In Park, BS, RN⁴; Lisiane Pruinelli, MSN, RN⁴; Suzan G. Sherman, PhD, RN³; Bonnie L. Westra, PhD, RN, FAAN, FACMI²⁴

¹St. Catherine University, Dept. of Nursing; ²University of Minnesota, Institute for Health Informatics; ³Fairview Health Services; ⁴University of Minnesota, School of Nursing

Abstract: The purpose of the study was to create an ontology representing musculoskeletal concepts using data extracted from a clinical data repository. The ontology connects flowsheet measures to higher-level EHR data concepts to support quality improvement work and research. The structured data derived represents a robust interdisciplinary research and quality improvement opportunity through examination of a large quantity of detailed assessments and interventions that reflect concepts such as mobility, gait, muscle tone, and level of independence.

Objective: Discuss the derivation process and utilization of an ontology representing musculoskeletal concepts using data extracted from a clinical data repository to support quality improvement work and research.

Introduction
Multiple conditions of an acute, traumatic or chronic nature can have an impact on a patient’s musculoskeletal status and functioning. Conditions such as arthritis, which was reported by 22.7% of adults during 2010-2012 (MMWR, 2013), may be exacerbated by overweight/obesity while also having a direct impact on the ability for patients to manage their health and their quality of life. Musculoskeletal conditions may require fine motor assessments of the hand or gross motor functioning demonstrated by a patient’s gait. The timing and effectiveness of assessments of a patient’s ability to be safe and independent are critical to care coordination across the interdisciplinary team. EHR flowsheets vary across vendors, health systems, and service lines, as well as change over time. To compare the health of populations, there is a need to map flowsheet data to higher-level concepts organized by clinical data models (ontologies) to evaluate care and outcomes.

Methods
The musculoskeletal ontology in this study was derived by examining a sample of 66,660 patients with 199,665 encounters that occurred between 10/20/10 and 12/27/13. Data was extracted from a Midwest health system’s EHR and loaded into a clinical data repository (CDR) created by the University of Minnesota. An ontology of musculoskeletal concepts was derived from the data and organized using a functional deficit clinical practice guideline and pertinent clinical questions pertaining to musculoskeletal assessments, interventions and outcomes. An iterative process was used to identify concepts from evidence-based practice guidelines, search for related terms, map flowsheet data to concepts, organize into a hierarchy, and have the process validated by another research team member.

Results/Conclusions
Manual mapping of this complex and overlapping inter-professional dataset resulted in the selection of 783 flowsheet measures. The value sets often had to be reviewed individually to determine the best categorization options. Flowsheet measures found within documentation templates for occupational and physical therapies as well as nursing presented some redundancy and overlap in value sets. Musculoskeletal flowsheet elements within these disciplinary templates also created challenges in that their often discipline-specific assessments had to be matched to and/or differentiated from other musculoskeletal assessment and intervention response sets. The challenges of separating and categorizing some of the concepts by their response sets as well as differentiating the utility of some assessment measures, may be resolved through mapping to standardized terminologies. This poster will present additional challenges and lessons learned in creating a useful clinical data model with related flowsheet data for inclusion in i2b2 and other common data models. The dataset reflects interprofessional care concepts that can be a resource for research, quality assurance/improvement and for quality reporting work like that required by multiple local and federal regulatory and monitoring initiatives. Informatics researchers will benefit by learning from and sharing their experiences in development of clinical data models that support normalization of flowsheet data.

Automated searches for personalized evidence to prevent hospital acquired infection

Amos Cahan, MD1,2, Sonya E Shooshan, MLS2, Laritza Rodriguez, MD, PhD2, Dina Demner-Fushman, MD, PhD2

1IBM T.J. Watson Research Center, Yorktown Heights, NY and 2The Lister Hill National Center for Biomedical Communications, National Library of Medicine, US National Institutes of Health, Bethesda, MD.

Objective
Hospital acquired infections result in considerable morbidity and mortality and high treatment costs. Medical caregivers often lack critical knowledge relevant to infection prevention1. We aimed to facilitate knowledge retrieval at point of care by use of an automated search filter accepting terms used in interdisciplinary team notes in an electronic health record system.

Methods
A “Risk for Infection” PubMed® search filter was constructed and its performance compared to an unfiltered search and to two existing search strategies (Table 1) using terms (tokens) extracted from clinical notes in a dataset of de-identified patients from a hospital electronic health record system. Three evaluators independently assessed the returned citations for relevance based on titles alone and titles with abstracts. The fraction of potentially clinically helpful citations of the top 5 citations returned (precision at 5) and inferred average precision were used as measures of search quality.

Table 1: Templates used for PubMed search

<td>Infection AND ((Term 1) OR (Term 2) OR (Term 3)) AND (prevent^ OR &quot;life style&quot; OR &quot;risk&quot; OR &quot;health behavior&quot; OR &quot;infection control&quot; OR &quot;causality&quot; OR &quot;prevention &amp; control&quot; OR prophylaxis OR prophylactic)</td>
</tr>
</tbody>
</table>

Results
Of 419 notes, 124 had a filled-out Risk for Infection health issue. The Risk for Infection filter provided at least 1 relevant citation of the top 5 results in nearly 2/3 of queries (Table 2). The precision and inferred average precision rates of the filter were significantly higher than an unfiltered PubMed search but lower than a proprietary search engine. Evaluators’ judgment based on title alone reliably predicted judgment by title and abstract (recall 88-99% and precision 88-98% for title compared to title and abstract).

Table 2: Precision at 5 retrieved documents and inferred average precision for 33 queries evaluated using judgments on titles alone and titles with abstracts under strict and relaxed conditions.

P@5, precision based on top 5 returned citations; InfAP, inferred average precision. Scoring rules: “Strict” - at least two evaluators considered it relevant or one considered it relevant and 2 “inconclusive”; “Relaxed” - a citation is deemed relevant based on the judgment of one evaluator, or on it being viewed as “inconclusive” by at least two evaluators.

Conclusion
A publicly available tailored PubMed search filter improves the quality of evidence for assessing and managing a patient’s risk of infection in a timely manner. More means to facilitate focused data retrieval by clinicians are warranted.

CDS, EHR and Pharmacogenomics to Estimate Warfarin Dosing

Pedro J. Caraballo, MD, Joseph Sutton, Padma Rao, Kelly Wix, PharmD, Wayne T. Nicholson, MD, PharmD, Cloann Schultz, MS, Carolyn R. Rohrer Vitek, MS, Robert Bleimeyer, Lois C. Hines, R.Ph., David Blair, MD, Mark Parkulo, MD., Mayo Clinic, USA

Introduction

Warfarin is an anticoagulant drug widely used in clinical practice to prevent thromboembolic events. Individual response to warfarin is influenced by multiple factors including variation in two genes (CYP2C9 and VKORC1). This drug also has a narrow therapeutic range and significant side effects; if the dose is too high it can promote bleeding and if it is too low it can allow thromboembolic events. Pharmacogenomics-based algorithms have been proposed to predict the individual initial therapeutic dose and to minimize the time patients are outside the therapeutic range. We present preliminary results of our attempt to develop and implement a clinical decision support (CDS) intervention (calculator/alert) integrated in the workflow to automatically estimate the initial warfarin dose using data from the electronic health record (EHR). We assess the availability of pertinent structured data and the functionality of two commercially available EHRs.

Methods

We used the algorithm published by Gabe et al. in 2008 to calculate the warfarin dose for the first 3 days. The variables and additional information included in the calculator/alert are in the Figure. Different functionality was available in each EHRs to implement the calculator/alert. On one EHR, we used the integrated expert rule system to generate an alert at the time of a “new” warfarin order (no previous warfarin order and normal PT/INR). The alert displayed the calculated dose and additional information. This alert was implemented in clinical practice. On the other EHR we used additional functionality to allow the provider to change data and recalculate the dose on the calculator/alert. However, this was a new untested functionality and production time was significantly longer.

Results

All the variables needed by the calculator could be captured discretely within the EHR by the CDS tool except for the indication for warfarin treatment and INR target. Clinical approval was difficult due to the outcome of recent randomized clinical trials that showed lack of clinical impact of pharmacogenomics testing and recommendations of current clinical guideline that do not support pharmacogenomics testing for warfarin dosing. In our institution, the number of patients with actionable CYP2C9 and VKORC1 results in the EHR in need of new warfarin treatment was very low. Between 9/18/2014 and 1/31/2015, the alert calculated the initial warfarin dose for four patients: #1 The indication was atrial fibrillation, the calculated dose was 6 mg vs. the provider ordered 3 mg; #2 Carotid dissection, 6 mg vs. 5 mg; #3 Prophylaxis for hip arthroplasty, 7.5 mg vs. 3 mg; #4 Prophylaxis for hip arthroplasty, 7.5 mg vs. 10 mg. In all 4 cases the therapeutic dose correlates with the dose suggested by the calculator. The CDS rule also identified 3 patients with VKORC1 results but without CYP2C9 results.

Conclusions

Warfarin dosing calculator can be developed using current functionality in commercially available EHRs. However, several technical and clinical barriers limit efficient implementation in routine clinical practice: lack of preemptive pharmacogenomics testing, lack of support by clinical experts and clinical practice guidelines, and the need of real-time capture of indication for warfarin treatment and INR target. Integration in the workflow is critical for adoption and interactive functionality (calculator/alert) is necessary to improve accuracy and safety.
A graph data model facilitates analysis of collaboration in an emergency department

Matthew B Carson, PhD¹, Stephanie J Gravenor, MS¹, Young Ji Lee, PhD, RN¹, Denise M Scholtens, PhD¹, Conor N Frailey, PhD¹, and Nicholas D Soulakis, PhD¹

¹Northwestern University, Chicago, IL

Introduction: Healthcare is a complex system of interactions between patients and providers on many levels. Collaboration between providers is an integral part of day-to-day operations in a clinical environment. During an encounter, a variety of personnel perform a different but overlapping set of activities in a cooperative effort to facilitate patient care. While an electronic health record (EHR) captures a patient’s medical history and health status, it does not promote the ascertainment of provider collaboration or workflow. Recently, graph databases have been used to store and analyze complex data sets in many industries. Unlike relational databases in which relationships between entities are hidden and can only be revealed by utilizing foreign keys and computationally intensive table joins, a graph data model allows information to be implicitly connected and thus relationships are easily accessible. This makes queries much faster, especially on large data sets. The lack of a rigid table structure makes graph databases highly flexible. Both nodes and relationships can have attributes, which allows for a rich domain representation. In addition, query visualization can easily reveal non-intuitive or distant relationships. These characteristics make the graph database an ideal framework for analyzing and monitoring collaborative patient care.

Objective: To create a high-throughput analysis framework based on a graph data model for identifying and describing provider collaboration in an emergency department workflow at Northwestern Memorial Hospital.

Methods: First, we mapped the workflow schema of business-as-usual care in the emergency department and identified activities performed at each stage in the care process. Second, we designed a graph data model to represent this process (a simple example is shown in Figure 1). Third, we collected data from the Northwestern Medicine Enterprise Data Warehouse (NM EDW), which uses a relational database management system, for 259,289 emergency department encounters from 2012 through 2014 involving 155,976 patients and approximately 11,676 providers. After cleaning the data, we implemented a Neo4j graph database for the set using our model.

Results: We identified > 75 million activities that occurred during the three-year period with an average of 290 activities per encounter. Approximately 1% of patients had > 10 encounters during that time. To ensure query feasibility, we focused on creating an efficient and intuitive graph model. For instance, defining hyperedges as nodes allowed us to identify which provider performed a specific activity during a certain encounter. Modeling time as a series of nodes and edges instead of a node attribute allowed for localized time and date searches. Modeling the workflow as a doubly linked list ensured traversal of steps in constant time. The poster will describe the conversion from workflow to data model, design lessons learned, and examples illustrating how collaboration can be quantified.

Conclusions: A graph data model can be used to analyze collaborative interactions in a complex healthcare environment. By incorporating a graph database, EDWs could provide meta-analyses and monitoring of collaborative relationships and workflows. The model could be expanded to include auxiliary health information such as genomic and proteomic data, regulatory pathways, and precision medicine information for more in-depth analyses.

---

Figure 1. An example of the graph data model showing the activities of three providers during one encounter. Node colors: ED workflow=black, encounter=orange, hyperedge=yellow, providers=green, time=red, activities=blue.
Survey of Mayo Clinic Trainees’ Knowledge, Attitudes, and Opinions Regarding Clinical Informatics

Tomas Carvajal, MD, Karl A. Poterack, MD
Department of Anesthesiology, Mayo Clinic, Phoenix, Arizona

Introduction

In 2010, the American Board of Medical Specialties (ABMS) approved subspecialty certification in clinical informatics (CI); the first board exam was offered in 2013.¹ There are now almost 800 diplomates in CI, but there is little data on what postgraduate medical trainees know about this new specialty. A previous study of medical students showed that only 28% were aware of postgraduate clinical informatics training.² A survey was undertaken to provide further information regarding the knowledge, attitude and opinions of trainees about CI.

Methodology

All Mayo Clinic residents and fellows at all sites (approximately 1300) were sent an email by the Mayo School of Graduate Medical Education asking them to voluntarily participate in an anonymous survey of their knowledge, attitudes, and opinions about CI. The survey included questions about demographic variables, fellowship career opinions, clinical informatics as a specialty, and basic CI knowledge. A mix of multiple choice and single or multiple answer questions were included. Survey was approved by the Mayo Clinic IRB.

Results

A total of 181 trainees completed the survey (14% response rate), with a mean postgraduate training level of 3.5 years. 50% (76/151) were female, and 56% (84/151) between 28-32 years old. 82% graduated from a North American medical school. 85% (27/181) stated their intention to complete a clinical fellowship, and 63% (108/172) believed that fellowships are necessary to attain clinical competence for successful practice. The decision for fellowship has remained stable in 62% (105/170) since medical school.

Only 24% (38/158) were aware of the availability of CI fellowship training, but 71% (111/158) were able to identify the correct definition of CI. Respondents who were not aware of CI training were almost as likely to correctly define CI. (69% v. 74%) There were a total of 70% (336/481) correct responses about the scope of practice of CI. In a mixture of questions about general knowledge based on a CI curriculum the average correct response rate was 63%.

When queried with regard to gathering information about management of a disease process, 33% replied they would initially use a medical reference source such as Pubmed®, 24% stated they would utilize a general web search tool (eg Google®), and 18% would use a specific web site. Of those who would use a specific website, 78% said they would use UpToDate®. These preferences did not show a significant difference between those who were and were not aware of CI fellowship training.

Conclusion

A sample of residents and fellows of different specialties at the Mayo Clinic were surveyed. The majority was unaware of the availability of a CI fellowship, in line with previously published data. However, there was some awareness of the definitions, scope of practice and core content of CI. Increasing the awareness of the fellowship and providing information on the formal training options is needed in the general medical trainee population.

A Comparison of Clinical Decision Support Interventions from Commercial and Internally Developed Electronic Health Records

Burcu Celik¹, Pegah Eghbali Alamdari¹, Karen Bavuso RN, MSN², Eileen Yoshida, BScPhm², Saverio Maviglia, MD MS², Thomas Wetter, PhD¹,², Roberto A. Rocha, MD, PhD³,⁴, Charles Lagor, MD, PhD⁵

¹Institute of Medical Biometry and Informatics, Heidelberg University, Heidelberg, Germany; ²Clinical Informatics, Partners eCare, Partners Healthcare, Boston, MA, USA; ³Brigham and Women’s Hospital, Boston, MA, USA; ⁴Harvard Medical School, Boston, MA, USA; ⁵Dept. of Biomedical Informatics and Medical Education, University of Washington, Seattle, WA, USA

Introduction
Healthcare Information Technology (HIT) vendors are increasingly offering Clinical Decision Support (CDS) to meet the demand from healthcare organizations for improving care and efficiency and reducing costs. Although there is an apparent benefit for healthcare organizations of not having to build and maintain CDS it is not evident to what extent their need for rules can be satisfied by vendor delivered inventories. CDS content often needs to be customized by individual organizations, particularly large academic settings. To better understand vendor CDS offerings we classified and compared the type of CDS content provided by a commercial EHR vendor to the internally developed CDS of Partners HealthCare System (PHS).

Methods
We received an inventory of 357 CDS interventions from an EHR vendor. The list included the intervention name, description, EHR module where available, display text, and intent of CDS. We classified the CDS interventions by type using a published taxonomy [1]. We also compared the vendor inventory to a similarly structured inventory of 656 CDS interventions developed internally at PHS, to determine which vendor CDS interventions could be implemented with minimal or no modifications.

Results
Of the 357 vendor CDS interventions analyzed, 10.4% were classified as “close match,” 21.8% as “approximate match,” 31.7% as “no match but related rules exist,” and 36.1% as “no match or related rule.” The first table shows an example of each category. The second table provides their numbers vs degree of match.

<table>
<thead>
<tr>
<th>Type of Match</th>
<th>Vendor CDS</th>
<th>PHS CDS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Match</td>
<td>Recommendation for annual eye exam if patient has diabetes</td>
<td>Adult diabetic overdue / almost due for ophthalmological exam, recommend exam</td>
</tr>
<tr>
<td>Approximate Match</td>
<td>Reminder to check serum potassium at least annually if patient has hypertension</td>
<td>If patient is on Thiazide or on an ACE Inhibitor then check potassium</td>
</tr>
<tr>
<td>No match but related rules exist</td>
<td>Patient with rheumatoid arthritis should not be given Methotrexate tablet 7.5 mg daily</td>
<td>Patient has rheumatoid arthritis but no disease-modifying antirheumatic drugs</td>
</tr>
<tr>
<td>No match or related rule</td>
<td>Notification that patient is on Medicare and overdue for certification</td>
<td>-</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Intervention type</th>
<th>Close Match</th>
<th>Approximate Match</th>
<th>No match but related rules exist</th>
<th>No Match or related rule</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Care reminders</td>
<td>21</td>
<td>36</td>
<td>29</td>
<td>59</td>
<td>145</td>

<tr>
<td>Patient-specific data displays</td>
<td>1</td>
<td>19</td>
<td>33</td>
<td>25</td>
<td>78</td>
</tr>
<tr>
<td>Incomplete documentation alert</td>
<td>10</td>
<td>10</td>
<td>12</td>
<td>13</td>
<td>45</td>
</tr>
<tr>
<td>Drug-age interaction checking</td>
<td>0</td>
<td>0</td>
<td>19</td>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>Other (18 further categories)</td>
<td>5</td>
<td>13</td>
<td>20</td>
<td>32</td>
<td>70</td>
</tr>
</tbody>
</table>

Discussion
Care reminders were the most frequent category, which is not surprising since they are a common form of CDS. However, the results showed that only 32.2% were candidates for implementation (37 Close and 78 Approximate Matches). The results suggest that larger healthcare systems can use vendor inventories as a starting point, but also need efforts to customize and build additional interventions. Smaller organizations with limited resources might benefit from using vendor provided CDS with minimal modifications.

HealthAlert: A Real-Time Health Monitoring App for Apple’s HealthKit

Basil Chaballout¹, Ryan J. Shaw, PhD, RN²
¹Duke University Computer Science Department, Durham, NC, USA
²Duke University School of Nursing, Durham, NC, USA

Introduction

Apple’s new “Health” app serves as a repository of health and fitness-related data on the iPhone. The app is used in tandem with HealthKit, a programming interface for developers to use accumulated data with their personally developed health applications. The significance of this lies in Apple’s recent partnership with Epic Systems, a medical records company that powers hospitals serving hundreds of millions of patients. Health has for the first time connected the individually operated mobile device to the provider’s electronic health record.

HealthAlert

Our team developed a mobile-based health monitoring solution, “HealthAlert,” that provides real-time health status notifications to a patient, and their chosen social network of family members, friends, or clinicians. This gives users choice over who receives notifications on their health data. It processes data via Apple’s secure HealthKit application programming interface (API) that connects with approved third-party devices and select EHRs. Using certified health-measuring devices, a patient can input his or her health data into Apple’s Health app in order for HealthAlert to analyze the data and send relevant notifications as a text or voice message. If the health metrics are outside of predefined ranges, an alert is sent to the patient’s selected social network indicating that something may be wrong. The ultimate goal of this application is to provide caretakers, clinicians, and family members with real-time reporting about a patient’s health symptoms to ensure that potential health issues are dealt with promptly.

Development and Testing

Our team consisted of undergraduate computer science students, physicians, and professors. Students were responsible for developing an application that allowed the input of the following information: oxygen saturation, heart rate, body mass, and daily activity. Next, we integrated the application with the HealthKit API. This allowed data from HealthKit approved third-party health monitoring devices, to be directed towards the HealthAlert app after it enters the Apple Health interface. This flow of data through Apple’s Health app provides a consistent and certified stream of data. After data is received from HealthAlert, it is analyzed in an external database hosted via a Bitnami server. This server is responsible for updates, additions, deletions, and reads from the external database. In order for notifications and calls to be sent out, the Twilio API on a separate Heroku server was required. The last step was to test the application. The program, which was built on Apple’s Xcode, was archived into an app file with the intent of ad-hoc usage, allowing for the application to be run on a select few devices for testing purposes.

Challenges

Although successful, the team faced challenges associated with decisions regarding real-time status alerts. This included deciding on how to react to data (i.e. hourly vs. daily) efficiently while not creating alert fatigue or sending out alerts from poor quality data (i.e. alerting upon poorly measured blood pressure data). Other challenges were developing an app that does not read data too frequently and drains the phone battery or use too much cellular data. Many of these challenges represented the velocity aspect of Big Data, and the concern with how to deal with data being inputted at an overwhelming rate. There were also development limitations that included only making the app useable with iOS at this time, dealing with costs associated with Twilio messaging, and HealthKit EHR integration in its infancy. Because of regulations and issues with legal systems, the team had to decide not to make an app that is a substitute for emergency contact, but rather just an adjunctive solution to monitoring wellness.

Conclusion

The process was overall a success and received positive reception by the Duke community. Our team has many future developments for the application on its agenda including a clinical trial and integration with our EHR.

Influences, Barriers, and Motivations for Healthy Behaviors Among Pediatric Cancer Patients: A Focus Group Approach

Michelle M. Chau, MPH\textsuperscript{1}, Elena J. Ladas, PhD\textsuperscript{1}, and Lena Mamykina, PhD\textsuperscript{1}

\textsuperscript{1}Columbia University, New York, New York

Introduction: Pediatric cancer survivors are joining a growing number of adolescents who suffer from chronic disease.\textsuperscript{1} With more effective therapies, the overall mortality from pediatric malignancy is decreasing. While this is encouraging, survivors are at higher risk for late-effect chronic medical conditions, such as obesity and cardiovascular disease, due to both the underlying condition and side effects of therapy. Interventions to manage nutrition, physical activity, and lifestyle choices can mitigate the effects of such diseases. Adolescents, in particular, confront a unique set of challenges in the self-management of chronic disease. Rapid social, physical, and emotional developments characteristic of this period impose added obstacles for the management of medical conditions. As such, interventions designed to address the distinctive challenges of adolescents with chronic diseases are needed.

Clinical interventions have attempted to utilize technology to improve the nutrition and physical activity of adolescents at risk for chronic diseases. Behavior monitoring, activity logging, goal setting, and gamification are common features used to engage adolescents in health. Researchers have used SMS, email, websites, and mobile applications to deliver such interventions. More innovative interventions are experimenting with image capture to log foods and nutrition. Many of these interventions are school-based and thus, have an inherent social support aspect. However, few applications engage adolescents with social media. Researchers have used posting and delivered interventions via social media. But, researchers have yet to widely incorporate and evaluate social media based intervention components.

Methodology: A focus group was conducted to gain understanding of the behaviors and barriers to healthy lifestyles experienced by pediatric cancer patients. Participants were recruited from the patient population of the Herbert Irving and Adolescent Cancer Center at Columbia University Medical Center. The group included four adolescents and young adults aged 13 to 25 who are in the transition phase (three months before completion of treatment) or are survivors of cancer (more than one year after completion of treatment). The Columbia University Medical Center Institutional Review Board approved this study.

Results: Several prominent themes regarding health management and behaviors emerged from the focus group including: 1) multi-level determinants of health behaviors; 2) initiation and maintenance of health habits; 3) inspirations for health; and 4) the importance of trust in evaluating information resources. In discussing individual, social, and environmental influences on health practices, participants highlighted how personal factors such as experiencing cancer affected health awareness and the development of nutrition and exercise behaviors. Family, friends, and their communities also played prominent roles in influencing how participants eat, cook, and purchase food. In terms of initiating and maintaining healthy habits, focus group participants stressed how simpler routines were easier to maintain. Group members also shared their initial inspirations for transitioning to healthier lifestyles as well as the motivations that keep them on track. When discussing actions to maintain health, many independently developed strategies to satisfy their appetites and cravings and to make decisions in suboptimal environments. Inspiration for health was often found through the use of social media applications and websites. Several discovered ideas for healthy living through photo sharing and social media platforms such as Instagram and Tumblr. Most participants tried fitness and nutrition applications but found them too complicated, not accurate, or lost motivation to continue using them. On the topic of information resources, participants identified trust as an important feature to look for when using applications. The group emphasized the importance of gleaning advice from trusted sources such as clinicians and verified applications.

Discussion: The focus group results suggest several design implications for adolescent interventions. Frequent participant use of social media to search for motivational messages and healthy living ideas calls for a prominent social media component in interventions. Food, recipe, and photo sharing could be useful motivators for adolescents. Personal and environmental influences on health habits suggest the need to tailor informatics interventions for specific dietary needs and individual circumstances. And lastly, trust emerged as an important requirement for information sources and applications. Our findings suggest a strong need to vet information and feature reputable sources in applications.

Predicting Clinical Laboratory Turnaround Time
Alex C. Cheng, MEM1, Marc Beller, PMP1, Joshua C. Denny, MD, MS1
1Vanderbilt University, Nashville, TN

Introduction
One challenge with clinical laboratory tests is the variability in the amount of time between when a test is ordered and when the result is available to the provider and patient. Studies have shown that increased mean turnaround time (TAT) and outliers are correlated with adverse outcomes such as increased length of stay in the emergency department. Knowing the time to result could help providers preemptively schedule follow up or mentally prepare to make a clinical judgment at a given time. Previous studies have successfully made improvements on the laboratory workflow that decreased TAT such as using pneumatic tubes for delivery or implementing computerized order entry. The goal of this study is not to decrease TAT but rather to predict the TAT at the time of provider ordering by modeling the process based on previous throughput data.

Methods
We developed our model on data from a pharmacogenomic screening test at Vanderbilt. The data we pulled for this study came from the laboratory information system between March 2013 and December 2014. Each sample had a specimen identification number that we used to track the progression of that sample through the process. We split our data randomly into development and validation cohorts. First, we calculated the throughput time for each sample based on its first and last event timestamp. For the parameters of the model, we considered four factors: the priority tag of the sample, the length of the queue or number of samples in progress when the sample arrived, the time of day the sample arrived, and the day of the week the sample arrived. In the queue length model, we attempted to fit a linear correlation between the queue length and throughput time. For all other parameters we plotted the distribution of TAT and set the prediction window to the 10th and 90th percentile of that distribution. Performance of each model was determined by two measures: the percentage of times the TAT of samples in the validation set fell within the prediction interval, and the size of the prediction interval as a percentage of the median prediction time.

Results and Discussion
We collected 42044 timestamps and for 3789 specimens. The 10th and 90th percentiles for the overall TAT in the development set were 85 hours and 507 hours respectively, making the prediction range 281% of the median TAT. This prediction range is too large to be clinical useful. The prediction ranges for the priority, hours, and days models performed similarly poorly compared to the overall distribution model. We considered narrowing our range by taking the 25th and 75th percentiles, but doing so would hurt accuracy percentages, which were already below 80%. There was a sudden drop in queue lengths after October 2013 that confirmed an operational observation that grants stabilize will give a better picture of the TAT. For any given sequence of consecutive samples, a longer queue at sample reception resulted in a shorter TAT. The laboratory seemed to allow many samples to build up before completing a large batch at once. Standardizing a queue length that triggers the rapid completion of all of the orders would make queue length at reception could be a good indicator of TAT.

Conclusion
We were unable to produce a model that accurately predicted TAT of genetic testing at Vanderbilt. However, we have created a framework for a simple TAT prediction model in clinical laboratory tests based purely on timestamp and priority data. With some modifications, this model could be applied to other laboratory tests. We will need to back up these quantitative measurements with qualitative observations of workflow. These predictive analytics could be coupled with changes in laboratory procedures to improve coordination of care.

Predicting The Initial Lapses After Alcohol Detoxification Using mHealth
Ming-Yuan Chih, PhD, MHA, University of Kentucky, Lexington, KY

Introduction
To prevent the relapse, a smartphone app, Addiction-Comprehensive Health Enhancement Support System (A-CHESS), offered ongoing support to alcohol addiction patients after leaving the residential care. Previously, some proximal risk factors (e.g., depression, self-reported in the A-CHESS Weekly Check-in) have been shown to predict well the repeated lapses in the coming week. However, the prediction of the initial lapses can be further improved. Based on the literature, demographics, distal risk factors (e.g., quite attempts), and other proximal risk factors (e.g., treatment participation, in this case, A-CHESS use) may predict alcohol lapses. This poster is to report on a predictive modeling study of the initial alcohol lapses among patients using A-CHESS after detoxification. Predicting the upcoming initial lapses can enable A-CHESS to offer instant and preemptive support to the patients.

Methods
Each of the 142 patients recruited from two treatment agencies at the Northeast and Midwest of the U.S.A received a smartphone with A-CHESS and a free 8-month phone/data plan before discharge. Demographics and distal risk factors were collected at the pretest. Proximal risk factors included the recovery progress scores in the A-CHESS Weekly Check-in and the A-CHESS use profiles developed from the A-CHESS use measures. Two datasets—142 initial lapse cases and 95 second initial lapse cases—were prepared for the model development and testing phases. In the model development phase, the Full Model that contained four demographics and 15 risk factors was developed using a logistic regression-based model. Using variable selection procedures, a model that contains only two significant predictors (i.e., gender and recovery progress, called the Simplified Model) was also developed. Model results were compared using area under receiver operating characteristic curve (AUC) analysis.

Results
In the model development phase using the 10-fold cross-validation method, the Simplified Model showed better predictability \((p=0.002)\) with the AUC up to 0.69, as compared to 0.55 in the Full Model (Fig.1). However, the Full Model showed better predictability \((p=0.045)\) using model testing data which were from later lapse episodes, with AUC up to 0.75, as compared to 0.65 in the Simplified Model (Fig.2). Detailed results will be provided in the poster.

**Fig. 1. AUCs in Model Development**

**Fig. 2. AUCs in Model Testing**

Conclusion
The Simplified Model may be better applied to the very initial lapses after patients leaving the facility, while the Full Model for the prediction of the initial lapses in the later episodes. The findings may provide an opportunity to improve the predictability of the existing lapse prediction service provided in A-CHESS. However, future research and more data are needed to further test and apply these findings.

Identifying High Risk of Hospitalization Among Long-Term Care Patients Using Conditional Inference Tree

Si-Chi Chin, Ph.D.
1 SEIU Healthcare NW Training Partnership, Seattle, Washington

Background
High users of health care services are a relatively small group of patients who account for a disproportionately amount of health care utilization. The elderly and disabled, who constituted around 25 percent of the Medicaid population, accounted for about 70 percent of Medicaid spending on services in 2003\textsuperscript{1}. Endeavors to reduce healthcare expenditure have included interventions that target individuals with long-term care (LTC) needs who are at particular risk for hospitalization.

Objective
The study aims to identify a population(s) of high risk of hospitalization. Specifically, this study aims to discover unexpected patient characteristics associated with high risk of hospitalization. The outcome of the study will inform the development of interventions strategies and to customize the interventions to meet specific needs of LTC patients.

Method
Conditional inference trees\textsuperscript{2} have been implemented in this study using data captured from Comprehensive Assessment Reporting Evaluation (CARE) tool. The data contains 76,873 LTC patients that reside in the State of Washington as of 2013. Conditional inference tree is an automated learning algorithm that uses Chi-square test statistics ($p$-value $\leq 0.05$) to measure the strength of association between any given split of a numeric variable (e.g. age or BMI) and the predicted variable (i.e. hospital admissions). The method discovers a sub-group of patients with statistically significant higher risks of hospitalization.

Results
Figure 1 provides two examples of conditional inference tree learning. The visualization shows that patients of age younger than 3 year old are in extraordinary risk of hospitalization (60\% as shown in Figure 1a). The combination of severe depression (Depression score (PHQ9) $> 16$) and morbid obesity (BMI $> 63$) contributes to extreme high risk of hospitalization ($> 60$% as shown in Figure 1b).

![Conditional Inference Tree Examples](image)

(a) Sub-group by age
(b) Sub-group by BMI and Depression Score

Figure 1: Example of conditional inference tree discovery

Conclusion
Conditional inference tree method is shown to be effective in identifying LTC patients with significant higher risk of hospitalization. The analysis suggests additional support (e.g. specialized/skilled care giver, education resource) is high on demand for young toddlers with disabilities and for LTC patient with morbid obesity and severe depression.

Privacy Concerns of Internet Users and Implications for Health Information Technology

Hwayoung Cho, MS, BSN, Rebecca Schnall, PhD, MPH, RN
School of Nursing, Columbia University, New York, NY, USA

Abstract Privacy is an important issue for enabling the use of health information technology. This analysis explored privacy concerns of Internet users. We analyzed survey data collected by the Pew Research Center. Most participants were worried about privacy when using the Internet and reported that it was impossible to be completely anonymous. These findings are of particular relevance to persons who use the Internet for meeting health information needs and highlight the importance of addressing privacy and security protections.

Introduction
Seeking health information online has become a popular method for health information seeking. Approximately 81% of U.S. adults reported having access to the Internet in 2012 and 72% of these users have looked online for health information1. Anonymity and privacy is a crucial consideration before use of health information technology.

Methods
This study used a survey dataset of the Pew Research Center collected between July 11 and 14, 2013. This data was collected initially to describe the use of Internet and mobile technology. Researchers conducted a nationwide survey in the U.S. using phone interviews in English of 1,002 adults >18 years old (502 landline and 500 mobile users). Participant selection was by random digit dial of both landline and cell phone numbers. A phone survey was conducted to examine how Internet users perceive anonymity and privacy while using the Internet. Survey questions focused on Internet use, accessing the Internet with a mobile device, sending/receiving email, and use of social networks. We calculated descriptive statistics on the survey data using SPSS.

Results
Sample: 497 (49.6%) participants were male and 505 (50.4%) were female. Most participants (87%) self-identified as White. 792 (79%) were Internet users, and 533 (53.2%) used Social networking sites. Findings: 59% of Internet users did not think it was possible to use the Internet completely anonymously. 18% had tried to use the Internet in a way that masked their identity from certain people or organizations. The most common way was to clear cookies and browser history (64%) (Figure 1). 41% of participants reported that they had deleted/edited something they posted in the past (41%). 35% did not use a website because it asked for their real name (36%). Some respondents reported past experiences that had resulted in adverse outcomes as a result of online activities, such as email/account taken over without permission (21%), trouble in a relationship with family/friends (13%), harassment (12%), stolen personal information (10%), money lost/reputation damage (6%), and physical danger (4%). 68% of survey respondents perceived that current laws were not good enough in protecting people’s privacy when using the Internet.

Conclusion
Findings from this analysis highlight some of the challenges that people currently experience using the Internet and how it relates to concerns over privacy and security. These are of particular relevance to persons who use the Internet for meeting their health information needs and highlight the importance of addressing privacy and security protections in these areas.

Appropriateness of Overrides of Age-specific Medication Alerts for Elderly Outpatients

Insook Cho, PhD1,2,3, Diane L Seger, RPh4, Sarah P Slight, MPharm PhD1,5, Karen Caputo Nanji, MPH1, Patricia C Dykes, PhD1, Olivia Dalleur, PhD1,7,8, Mary G Amato, PharmD MPH1,6, David W. Bates, MSc1,3,4

1Brigham and Women’s Hospital, Boston, MA, USA; 2Inha University, South Korea; 3Harvard Medical School, Boston, MA, USA; 4Partners Healthcare Systems, Inc., Wellesley, MA, USA; 5Durham University, Durham, UK; 6MCPHS University, Boston, MA; 7Louvain Drug Research Institute, Universite catholique de Louvain (UCL), Belgium; 8Cliniques universitaires Saint-Luc (UCL), Brussels, Belgium

Abstract: Inappropriate medication prescribing by physicians represents an important preventable cause of morbidity and mortality in the elderly. A well-designed geriatric decision support system can improve prescribing by recommending appropriate doses and drugs for this patient group, but prescribers do not always follow these alert recommendations. The objective of this study was to assess what override rates that could be considered reasonable in outpatient settings.

Introduction: Health-care systems worldwide are dealing with increasingly elderly populations, and this is increasing the numbers of patients with comorbidity who are taking multiple medications. One previous study estimated an incidence rate of 27% for adverse drug events in primary care in the outpatient setting, with most problems occurring at the ordering and monitoring stages of care.1 Computerized provider order entry with clinical decision support has been promoted as one of the most promising interventions for improving medication safety, but prescribers do not always follow the recommendations of the alerts, citing their irrelevance and annoyance with interruptions in their clinical workflow. Careful investigations have revealed that many of these alert overrides are clinically inappropriate, while others are clinical justified. However, it remains unclear what a reasonable override rate should be in older outpatients.

Methods and Results: We obtained data on age-specific alert overrides and the coded reasons for overrides cited by providers at the time of prescribing from outpatient clinics and ambulatory hospital-based practices within a large integrated healthcare system from January 2009 to December 2011. For detailed chart review, a group of six trained clinicians developed the appropriateness criteria with good interrater reliability (κ=0.86). We stratified providers according to override frequency and then obtained samples of 200 overrides from the top-25 providers who overrode the most and 600 from the remaining providers. We measured the rate of total overrides and rates of appropriate overrides by drug class according to the ATC (Anatomical Therapeutic Chemical) classification system. We also examined the prescription types (new vs. renewed prescriptions) and the reasons for overrides according to provider.

In total, 11,235 age-specific alerts were triggered by 827 providers during the study period, of which 79.6% (8,943) were overridden. The override rate by the top-25 providers was 97.6%. The chart review revealed that the overall appropriateness of overrides was 40.3% (308/765); it was 50.8% in the top-25 group and 36.6% in the remainder group. Almost one-quarter of the alerts overridden concerned drugs used to treat anxiety (psycholeptics); the appropriate override rate was 16.2% (top-25, 17.3%; remainder, 15.8%). Other frequent overrides with appropriate override rates included neuroleptics (top-25, 72.4%; remainder, 52.0%), anticholinergics (top-25, 4.0%; remainder, 8.0%), and psycholeptics (top-25, 95.7%; remainder, 56.5%). The proportion of renewal orders was higher in the top-25 group (51.8%) than in the remainder group (30.5%). However, for the override reason of ‘patient has tolerated this drug in the past’, the proportion was higher in the remainder group (63.9%) than in the top-25 group (57.9%).

Conclusion: The appropriate override rate of age-specific alerts was four out of ten. Seven out of ten drugs overridden were psycholeptics, neuroleptics, and anticholinergics. The common characteristics of these medications were a long history of being taken and frequent renewals repeating the overrides, which contributed to the high override rate of the frequent overrides. Interventions are needed to improve alert appropriateness and address providers’ overriding behavior in the outpatient setting.

System Architecture of CDC I-SMILE Recommendation Engine

Edward Choi, MS¹, Jina Dcruz, PhD², Sizhe Lin, BS,¹ Aashu Singh, BA¹, Hang Su, BA¹, Kelly Ryder, MPH³, Sridhar R. Papagari Sangareddy, MS², Herman Tolentino, MD², Jimeng Sun, PhD¹

Description

Learners or problem-solvers in applied training programs at CDC solve complex tasks that often require knowledge outside their expertise. Moreover, selecting the learning content that best suits the needs for each research can be difficult, because the knowledge to be learned is not in the researcher’s domain. CDC’s I-SMILE recommendation engine is a system with a goal of facilitating a customized retrieval of learning content for users in need of knowledge outside their domain. The architecture of the system is given in Figure 1.

Figure 1. I-SMILE Recommendation Engine System Architecture

The system retrieves learning content assembled from the Internet. The system has indexed course descriptions of massive open online courses (Udacity and Coursera), descriptions of books from Google Books, and PubMed abstracts from the CDC-based learning content management systems. The collected documents are parsed by using natural language processing (NLP) techniques and indexed in a database.

The system uses a hybrid approach of recommendation, a combination of content-based search and user-based search. Content-based search is a conventional method for document searching, which uses a vector-space model as the core method. For example, if a user enters “health information exchange” as the query, the system will calculate the cosine similarity between the query and the documents to retrieve informative documents that contain those words. User-based search is a variation of collaborative filtering, which makes recommendations without considering document contents. For example, let’s assume that John and Mary, after searching for some query q, clicked documents d₁, d₂, d₃ and d₁, d₃ respectively. Then we can assume that Mary will also be interested to have a look at d₂, and the system will recommend d₂ to Mary and other users who use a query similar to q. In addition to traditional collaborative filtering, which only uses information regarding users’ choice of items by click-through data of all users, our method exploits user profiles provided by users. Users can specify learner background, expertise level, and learning style to customize their profile. Queries entered by the user could be expanded using taxonomy or controlled vocabulary provided by the user to increase system recall. For the informatics domain, we tested use of Medical Subject Headings controlled vocabulary for search and filtering. The system includes a mechanism to rate retrieved contents by the end users.
Design guidelines for effective data visualization of sensor monitoring data

Yong Choi, MPH\textsuperscript{1}, George Demiris, PhD\textsuperscript{1}, Arjmand Samuel\textsuperscript{2}, Danny Huang\textsuperscript{2}

\textsuperscript{1}University of Washington, Seattle, WA, USA; \textsuperscript{2}Microsoft Research, Seattle, WA, USA

Introduction

Unobtrusive monitoring of older adults with the use of smart home sensor systems presents a unique opportunity to improve the health and wellness of older adults. However, customizing deployment to address different environments is a key challenge. Furthermore, once a sensor system is deployed, effective processing of a large sensor data set to make meaningful inferences remains another major challenge. Even when successful algorithms have been developed to analyze the data, older adults as end users are not capitalizing on the value added by the data analysis, if findings are not communicated back to them in an effective and comprehensive manner. The goals of this project were: a) to test a platform for sensor system deployment that allows for standardization across sites; b) to design visualization prototypes that demonstrate sensor data; c) assess older adults’ needs and preferences of various visualization approaches; and d) recommend design guidelines for effective data visualization for sensor monitoring.

Methods

This project includes two phases. In the first phase we used the Microsoft Lab of Things (LoT)\textsuperscript{1} platform to deploy a sensor system within a multi-person residence\textsuperscript{2}. LoT is a software infrastructure that simplifies the interconnection of multiple sensor devices across diverse environments and the development of software applications for processing sensor data\textsuperscript{3}. We deployed various sensors (e.g., door/window sensors, multi-sensor collecting data on motion, temperature, luminosity, and humidity) using the LoT platform. Furthermore, we developed a data visualization application that graphs sensor data within the LoT platform to assess the sensor data visualization needs of older adults and their caregivers. We conducted an online survey with 19 older adults and caregivers to assess their visualization needs and preferences. In the second phase, we engage older adult participants within the design of data visualizations derived from the sensor data through a participatory design approach and plan to develop a set of design recommendations based on older adults’ feedback to be reviewed by experts in the field for face validity.

Results

Our evaluation of the visualization application with older adults 65 years of age and older and caregivers in Phase 1 of the project revealed findings that have clear implication for future sensor data visualization. Participants indicated the importance of knowing the time when the last sensor event happened, the amount of time spent in each room, and a total activity level house-wide. In addition, the caregivers and older adults differed significantly in their perceived usefulness of the system. While older adults indicated that the visualization was hard to understand and questioned the usefulness of the system, caregivers expressed that the system was easy to learn and useful for monitoring older adults health and wellness. Currently we are conducting the second phase of this study that includes participatory design and interview sessions with older adults and visualization experts.

Discussion

The smart home sensor data have potential to be valuable resources for older adults and their caregivers in managing health and wellness. However, there still remains a challenge in increasing acceptance and usage of these technologies among older adults. An informative guideline to develop effective data visualization for sensor monitoring can facilitate the adoption of smart home technologies.

The authors wish to thank Dr. Thai Le and Mr. Christian Bock for their contributions to data collection and analysis during the first phase of the project.
HomeSHARE: A Distributed Smart Homes Testbed Initiative

Kay Connelly, PhD1, Blaine Reeder, PhD2, Amanda K. Hall, PhD3, Kelly Caine, PhD4, Katie Siek, PhD1, George Demiris, PhD3
1Indiana University, Bloomington, IN; 2University of Colorado, Aurora, CO; 3University of Washington, Seattle, WA; 4Clemson University, Clemson, SC

Introduction
Smart homes have great potential to support independent living for older adults as the global population ages1. However, in-home technology researchers typically: 1) conduct small-scale feasibility studies; 2) recruit participants through convenience sampling; 3) and expend substantial resources to build or customize technologies. While important, these efforts often fail to translate or scale beyond their original settings. A current lack of in-home technology research infrastructure prevents investigators from answering research questions that can generalize to larger populations. The Home-based Smart Health Applications across Research Environments (HomeSHARE) initiative seeks to develop a geographically distributed smart homes testbed that will overcome the challenges of conducting large-scale studies. Founding HomeSHARE sites are located at Clemson University, University of Colorado, Indiana University, and University of Washington (Figure 1).

Methods
The HomeSHARE team has extensive experience in informatics, human-computer interaction, privacy, gerontology, user-centered design, and patient-centered research. Our current goal is to characterize the research needs of investigators in these and other areas including artificial intelligence, augmented cognition, and allied health. Starting in September 2014, we have engaged researchers at research conferences and networked through existing professional contacts to determine discipline-specific research questions, governance requirements, and technical issues. International professional events that we targeted included the Gerontological Society of America (GSA) Annual Conference, AMIA Annual Symposium, and AAAI Spring Symposium. Information was collected using individual interviews, focus groups, and online surveys. For example, at GSA we recruited gerontology researchers for half hour interviews or solicited contact information for phone interviews or online survey completion at a later date. This planning phase will complete in August 2015.

Results
A white paper to inform the development phase of the HomeSHARE initiative is in-progress. Researchers from gerontology, nursing, medicine, informatics, and artificial intelligence collectively agree about the potential utility of a geographically distributed smart homes testbed. Researchers recognized multiple potential benefits from a testbed such as standardization across various environments, access to large data sets, and more diverse study populations. They also identified potential challenges that included additional processes before a study could be implemented and overcoming institutional barriers. While research questions will differ by discipline, the same governance issues apply to all investigators who will participate in the HomeSHARE effort. For example, a health researcher might be interested in how sensor-based measures can be used for health-related decision-making to support independence at home while an artificial intelligence researcher might be interested in questions related to automatic system optimization based on emerging performance factors of networked home sites. Governance issues that apply to all researchers include criteria for participation, shared management responsibilities, and data control and sharing.

Conclusion
Full results of the HomeSHARE planning phase will be presented at the AMIA Annual Symposium 2015.

Besta, Milan, Italy; 7Istituto di Tecnologie Biomediche, Consiglio Nazionale delle Ricerche, Italy

Introduction

The role of nutrition in health management is known since ancient times, but its relevance was boosted in the last decade by epidemiological studies pointing out diet as a key risk factor for a number of diseases. Several parallel studies indicated that the traditional approach, focused on caloric and macronutrients intake, fails in capturing essential features of dietary risk factors and specificities associated to the host’s unique genetic background. Nutrigenomics, which already demonstrated that genetic polymorphisms influence response to diet, can offer a powerful approach to unravel the effects of diet on health. This emerging field of research and its translation into prevention strategies needs new tools enabling the systematic collection of a variety of data.

Methods and results

We developed an integrated platform, called Dietary Monitoring Solution (DMS), to collect phenotypic, genetic and lifestyle information linked to a mHealth application providing personalized dietary indications. Our DMS was designed according to the indications of clinicians, geneticists and nutritionists and it is composed by:

a) a web-based platform, based on a framework dedicated to CRF management;

b) a software, calculating the macro and micronutrients intake from each food/meal;

c) a mHealth application monitoring and guiding the subject in his/her ecological context.

The web-based platform is used by the clinician to create the CRFs containing patient’s data (i.e. personal medical history, physical, laboratory examination, therapies, etc.) and by the nutritionist to collect the patient’s dietary habits, through interviews and food frequency questionnaires. Dietary information, collected through 24h-recall interviews, includes a description of foods consumed during each meal and their macro and micro nutrients composition, computed by a software combining input data from dietary interviews and food nutrients composition, from validated food databases. Genotypic data are managed by the healthcare professional and can be uploaded from PED and MAP files, which constitute standard formats for genomic analysis software. The mHealth application is dedicated to the subject and is used to track his/her diet and lifestyle. In addition it provides access to a semi-automatic Decision Support System (DSS), which suggests risk reduction behaviors, considering individual genetic data, particularly those for which there are well established evidences of interaction with the diet. All suggestions provided by the DSS need to be validated by healthcare professionals. This platform was used to collect information from more than 500 volunteers participating to ATHENA, a European Commission FP7 project (Grant Agreement 245121), in three recruitment sites. It also stores volunteers’ genetic data, as generated by genotyping the DNAs with a commercially available chip containing ~280K highly informative genome-wide tag Single Nucleotide Polymorphisms. The user with “Data Manager” role can extract anonymous data from the platform and analyse data, homogeneously collected through the web-based platform, from all the centres taking part into the project.

Conclusion

DMS novelties rely on the possibility for the professional to refine data collection tools, to “supervise” the suggestions proposed by the DSS and to interact with the patients, responding in this way to the concerns raised by healthcare professionals toward the DSS approach. Future studies are envisaged to evaluate users’ compliance and usefulness of the mHealth application suggestions.
User-Centered Design of the Clinical Dashboard for the MySafeCare Patient Safety Reporting System

Brittany Couture1, Jessica Cleveland4, Awatef Ergai PhD4, Zachary Katsulis4, Naoaki Ichihara MD, MPH, PhD2, Ann DeBord Smith MD, MPH1,3, Esteban Gershanik MD, MPH, MMSc1,3, Frank Chang2, Alicia Goodwin5, Sarah A Collins RN, Ph.D.1,2,3

Keywords: Patient Centered Care, Patient Safety, User-centered design

Introduction/Background

Patients are a unique source of information on potential threats to safety and quality of health care.1 Past research on patient-perceived safety threats relied on retrospective surveys and interviews. Innovative technology may aid in overcoming barriers that prevent identification of safety threats experienced by patients.2,3 Consumer safety reporting systems exist.4,5 Yet, we know of no system that captures in real time patient perceived threats to safety while in the hospital as a learning health system to mitigate risks before they occur. We are developing MySafeCare (MSC), a web-based/mobile enabled application that provides patients, families and their friends an electronic, real-time way to communicate safety concerns to hospital staff. MSC includes a clinical dashboard for staff to view and trend patient/family reported concerns and document/communicate follow-up. This poster describes our user-centered design for version 1 of the clinical dashboard.

Methods

The targeted users of the version 1 dashboard are Nurse/Medical Directors at Brigham and Women’s Hospital. We conducted 3 Interviews with Nurse Directors and 2 Interviews with Medical Directors. Each interview lasted 30-60 minutes and focused on probing questions to determine the best ways to accurately and efficiently display submitted concerns to dashboard users. The research team analyzed interview notes to extract design requirements by turning them into structured user stories that described functions directors wished to see. An example user story is: “As a dashboard user, I want each case displayed as a separate row on the dashboard, so that I can address individual concerns instead of all of them as a summary”. Next, validated user stories were categorized into minimally releasable features (MRFs), documented using Jira Software (c), prioritized, and confirmed with unit directors.

Results

We defined 25 MRFs after 5 interviews and selected 12 of these to appear in v1. Included in those 12 are: landing page view, status filter, dashboard notifications, and dashboard trending. Each MRF had 1-7 associated specific requirements, for example the drill down case view (Figure 1) includes identification of submitter, concern type, and level of concern.

Discussion/Conclusion

Interviewing targeted users to obtain requirements for dashboard functionality gave us valuable insight to meet our users’ needs. From this qualitative process, we were able to prioritize development efforts on requirements that surfaced during multiple interview sessions, such as trending number or types of concerns in a graphical manner. Through collaboration between our technical team and interviewing team we targeted features that are important to users while also technically feasible to complete before v1 release. This is part of an iterative design process, including design evaluation of each release version to optimize the functionality of the dashboard. The same user centered design methods are being conducted with patients and families for development of a user friendly Patient Facing Application.

Design and Evaluation of an Infection-Risk Monitoring Application

Matthew C. Cowperthwaite, PhD, Anurekha Ramakrishnan, MS, Mark G. Burnett, MD, K. Michael Webb, MD, Douglas J. Fox, MD

NeuroTexas Institute Research Foundation, St. David’s Healthcare, Austin, TX 78705

The massive quantities of data generated during routine clinical practice and captured by hospital EMRs hold the great promise to improve the quality and efficiency of healthcare, while also reducing the cost of healthcare delivery. NeuroTexas Institute Research Foundation (NTIRF) at St. David’s Medical Center has been developing and deploying an innovative research database – ProSpect – to capture a wide range of clinical and outcomes data describing neurological and neurosurgical treatments. ProSpect will leverage open-source APIs for rapid implementation of ‘apps’ that support both patients and clinicians.

Currently, ProSpect aggregates clinical data from 6 different hospitals owned by St. David’s HealthCare in Austin, TX, a large neurosurgery practice, and local outpatient imaging providers. The ProSpect project leverages a custom, in-house developed database platform written in SQL. The primary database implements a “schemaless” Entity-Attribute-Value (EAV) model in which data are stored as key-value relationships for each patient. ProSpect collects clinical data including nursing reports, surgery reports, medication reports, CPT and ICD9 codes from St. David’s Electronic Medical Records (EMR). ProSpect also includes a dedicated Merge eFilm (Chicago, IL) Picture Archiving and Communication System (PACS) server for collecting radiological images. Data feeds from various sources are executed and loaded into ProSpect on a daily basis.

Currently, ProSpect contains data for 3,651 neuro-patients treated since 2012. The most common diagnoses are lumbar and cervical spinal spondylosis, displacement of lumbar disc, and spinal stenosis. There are 4,162 distinct neurosurgeries performed on 3,184 patients. 525 patients had a second hospital encounter within a year of surgery, with a median readmission time of 50.5 days. Readmissions may occur for a planned procedure (e.g battery replacement for a spinal simulator) or an unplanned procedure (e.g. a revision or complication).

Our team is interested in surgical-site infections (SSI), and here we present a pilot study that focuses on identification and analysis of risk factors for SSI. Through a literature review and consultation with neurosurgeons and other clinical experts, we identified 50 potential risk factors associated with SSI. The factors were grouped into demographic factors (age, ethnicity etc.), patient co-morbidities (diabetes, hypertension, etc.), surgical factors (surgery duration, blood loss, etc.), and clinical factors (e.g. anemia, inflammatory signals). Entity mapping was done using associated rules-based tagging. The Infection rate was 4.1% (33 out of 790 Lumbar fusion surgeries in 2014 and 1st quarter of 2015). Feature selection was done using Logistic Regression with backward elimination. Class imbalance was handled using Weighted Logistic Regression (WLR) and Synthetic Minority Oversampling Technique (SMOTE). WLR, Decision tree and random forest models were built for classification; with Random forests providing the best precision (positive predictive value) of 70.2% for the infection class. The significant predictors were post-op hemoglobin count, re-fusion surgery, removal of implanted hardware, number of prior surgeries for the patient, Arthrodesis status, smoking and BMI.

The “Infection Risk” app will present a patient and clinician-friendly view of infection-risk based on patient risk factors identified by the model. A prototype of this app is designed using Twitter’s bootstrap, d3.js and JQuery, and runs on standard web, tablet, and mobile devices.

In summary, NTIRF has developed a clinical research database – ProSpect – that gathers and assimilates clinical data spanning the continuum of care to create a detailed portrait of the care delivered and patient recovery and health. We have developed an “Infection Risk” app that will present patient and clinician-friendly view of infection-risk, using ProSpect as the primary data source. We plan on integrating this app to use the open-source SMART API platform in the future.
To Improve Sensitivity and Specificity in Early Detection of Sepsis

Vira S. Danak, MS1, Albert Riedl, MS1, Hien H. Nguyen, MD1
1UC Davis Health System, Sacramento, California, USA

Introduction
The U.S. National Center for Health Statistics of the Centers for Disease Control and Prevention (CDC) has issued estimates derived from claims data that sepsis cases have increased in the U.S. from 621,000 in the year 2000 to 1,141,000 in 2008. With increased use of electronic health records (EHR), a significant amount of secondary EHR data is collected. This data can be used to develop and implement an Early Warning Scoring system (EWS) to identify septic patients earlier and help improve in hospital mortality of septic patients. Since early detection of sepsis in adults is challenging, this thesis explores and proposes opportunities to improve the accuracy of the early warning scoring systems and alerts used to detect sepsis. This study approach is to identify new vital sign thresholds in SIRS criteria for different age groups that can help improve the efficiency of the current sepsis alert at UC Davis Health System (UCDHS). Evaluating these new scoring systems shows improved sensitivity and specificity in early detection of sepsis in adults.

Methodology and Evaluation
The principal objective of the study is to improve the sensitivity and specificity of the current sepsis alert at UCDHS. We use traditional systemic inflammatory response syndrome (SIRS) criteria to alert bedside clinicians to adult patients with possible sepsis and it has helped us meet our goal of improving sepsis related mortality by 15% from 2011-2013; but the non-specific nature of SIRS criteria has led to alert fatigue. In order to improve identification of patients with SIRS and infection, we collected data on patients with clinical infection by asking physicians to answer a question regarding the presence of suspected infection for every patient who is admitted to the hospital from the emergency department. The Infection Answer is basically a categorical variable with Yes/No response. Since a clinician’s interpretation of patient’s condition and judgment is most crucial, this study considers Infection Answer (or Order_Answer) as a gold standard to compare with and evaluate the accuracy of the sepsis alert. To meet this objective and propose future goals for improvement, current sensitivity and specificity of the alert is evaluated/calculated using Structured Query Language (MySQL workbench 6.3) and Statistical Analytical Software (SAS 9.3). Having obtained the current accuracy of the sepsis alert then, data analysis is carried out to explore and meet the other research objectives.

1. The evaluation of current sensitivity of the sepsis alert at UCDHS resulted in 68.13% and specificity of the sepsis alert at UCDHS resulted in 52.46%. Secondly, the alerts results show that alert is over firing based on the findings that around 48% of the order response to the alert is “overridden” by the clinician and the Infection Answer is “No” for those alerts.
2. In this research, pulse is observed to be the foremost participant influencing over firing of the alert and therefore mean pulse thresholds were used to divide the overall adult population in different age groups.
3. Furthermore, results from logistic regression showed that temperature and WBC are associated in determining the infection answer by the clinician. To reaffirm this, the analyses were computed two ways. 1. Independent vital signs participating most frequently in firing of the alert; 2. Vital signs associated in modelling the Infection Answer by the clinician. Both the analysis showed similar results that pulse, WBC and temperature are more associated with infection. Therefore, the new pulse and temperature thresholds were computed with CART analysis in SPM. The specificity highly increases in all the age groups when new Pulse and Temperature thresholds are implemented (Age>=18 and <=39(n=282): 97.70% ; Age<=40 and <=59 (n=616): 95.97% ; Age>=60 and <=79 (n=446): 96.78%; Age >=80(n=86): 98.93% ) These findings can help improve early detection of some patients and make the SIRS criteria more specific.

Conclusion
On the basis of the different analyses, it can be concluded that more accurate EWS and alerts can be developed. This can be achieved by using Age-Pulse association to divide adult sepsis population in different age groups and by implementing different temperature thresholds across these different age groups. It may be possible to increase the specificity of the sepsis alert and reduce the over firing of the alert to avoid alert fatigue among clinical professionals.

Feasibility of Converting the Medicare Synthetic Public Use Data Into a Standardized Data Model for Clinical Research Informatics

Introduction

A challenge in health care informatics is the availability of actual patient data. Virtually all currently available sources of longitudinal data require a data use agreement and data security plan to ensure patient privacy; therefore, it is challenging to develop tools and share best practices that are effective on “real-world” health data. Recently, the Centers for Medicare and Medicaid Services (CMS) released de-identified synthetic Medicare public use data files (SynPUF) to facilitate the development of data analysis tools. To date, the usability of this data for clinical research informatics purposes has not been reported.

Study Aims:

The purpose of this study was to assess the feasibility of using the SynPUF data for clinical research informatics by developing the specifications for conversion to the Observational Medical Outcomes Partnership (OMOP) Common Data Model version 5.0 (CDMv5). A secondary aim was to compare SynPUF to the actual CMS 5% sample limited data set (LDS) to determine the limitations to applying the specification to actual CMS data.

Methods:

We assembled a multidisciplinary, cross-organizational team and developed open-source algorithm specifications to extract, transform, and load (ETL) the raw text files into CDMv5 using publicly available Observational Health Informatics and Data Science (OHDSI) tools. We used the White Rabbit tool to characterize the raw data, and the Rabbit-In-A-Hat tool to create mapping documentation. Each SynPUF variable was mapped to the appropriate table(s) into CDMv5, including variables about people, visits (including hospitalizations), conditions, procedures, deaths, and drugs. We compared the fields available in SynPUF to those normally available in the CMS 5% sample LDS.

Results:

We were able to map or use 282 of 294 (96%) non-empty data fields in the raw SynPUF data to populate at least one table in CDMv5. Fields that were not mapped included 9 annualized cost fields (identical to more detailed cost information already mapped), 1 length of stay field (admission and discharge date already mapped), and 1 date field (inpatient “claim through” date selected instead of “discharge” date). Medical conditions, procedures, visits, drug records and costs accounted for most of the available data. Overall, the usefulness of the data was high with appropriate values in most fields examined. Limitations of SynPUF compared to the 5% sample LDS included missing enrollment dates, limited data on location of care, lack of charged amounts, no modifiers for procedure claims, no specialized laboratory-reporting fields, no revenue codes, and no durable medical equipment, home healthcare, or hospice care data. The file structure also differed across years within LDS, and also between LDS and SynPUF.

Conclusions:

The SynPUF data from CMS represents a usable and valuable tool for clinical research informatics. The resulting specification will support the development of open source ETL software that will enable researchers to explore the SynPUF data in CDMv5. Researchers will then be able to leverage the OMOP standard vocabulary, take advantage of existing exploratory and analytical tools being developed by OHDSI and others, and develop new tools. In terms of our secondary aim, one key limitation is that, because of the missing variables and different data structures, SynPUF does not facilitate a complete “plug and play” process for other CMS datasets including the 5% sample LDS. As a result, additional work will need to be done to adapt the ETL specification to actual CMS datasets. While the synthetic nature of the data prevents it from being used for clinical research purposes, it appears to be useful for methodological research and for testing tools for manipulating and analyzing health care data.
Information System for Mobile Immersive Learning Environment for Just-in-Time Learning in Public Health

Jina Dcruz, MSW PhD², Kelly Ryder, MSW MPH³, Edward Choi, MS¹, Sizhe Lin¹, Aashu Singh, BE¹, Hang Su, BEngg¹, Sridhar R. Papagari Sangareddy, MS², Herman Tolentino, MD², Jimeng Sun, PhD¹

²Centers for Disease Control and Prevention, Atlanta, GA
³Association of Schools and Programs of Public Health, Washington, DC

Abstract

I-SMILE (information system for mobile immersive learning environment) is an interactive, immersive, and context aware social learning environment that is based on mobile and cloud platforms. It delivers learner-centered, just-in-time learning for the public health workforce as they solve problems in a challenging and a rapidly evolving environment. From the perspective of public health workforce development, we present a business case, functional requirements, prototype, and lessons from a formative evaluation study.

Description

The practice of public health is rapidly evolving with increased integration opportunities among key stakeholders in an increasingly complex health system, rapid advances in information technology, and an ever growing disease burden across the globe. A competent and capable workforce [1] and the ability to learn in real-time are necessary to address these challenges to maintain and enhance public health capacity and service delivery functions to improve population health. However, a significant crisis exists among the public health workforce fueled by health system and policy changes. Aside from the challenge of an ageing and inadequately trained existing workforce, public health also faces the additional challenge of diminishing resources that constrain recruitment and hiring of a skilled entry-level workforce. Public health informatics capacity building has emerged as a critical workforce need to strengthen the current public health workforce infrastructure and service delivery [2].

Even with a well-structured applied, competency and problem-based curriculum, public health training programs face the challenge of understanding the rapidly evolving training needs in an increasingly complex public health landscape and responding to them in a timely manner. This radical and rapidly changing context requires equally radical and disruptive approaches to applied training. We propose a new paradigm for applied training that is context-aware, learner-centered, and just-in-time. The new paradigm is based on innovations in technology in the areas of mobile computing, machine learning, and distributed computing.

I-SMILE (information system for mobile immersive learning environment) is a collaborative project between the Georgia Institute of Technology College of Computational Science & Engineering and the Centers for Disease Control and Prevention to design, develop, and evaluate an innovative, just-in-time learning system for applied training in public health informatics. On the basis of existing work regarding learning management systems, learning analytics and connectivism as a framework for learning [3], the project is expected to bring together advances in computing and education technology. Technical features of I-SMILE include, but not limited to identification of key domain concepts from problem statements provided by user, search, retrieval and indexing of relevant learning content, Medical Subject heading (MeSH) keyword mapping to increase search relevancy, responsive user interface, user similarity matching, and problem bank generation. Through its unique features and functions, I-SMILE aims to support the evolution of an agile and capable public health workforce in an increasingly complex information rich environment. Usability testing with current CDC Informatics fellows will be conducted to evaluate the ‘proof of concept’ mobile prototype of I-SMILE.

The TISS standard for electronic exchange of information in the private health insurance sector in Brazil

Sergio P. de Oliveira1, José F. R. Costa1,2

1 National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, RJ, Brazil 2 National Supplementary Health Agency

Introduction
In Brazil, the health system consists of a complex network of health care providers, forming a public private mix. The Brazilian Federal Constitution gives the State the duty to promote universal and equal access to programs and health services to all Brazilian citizens, guaranteed by the Unified Health System (SUS), which is public. The constitution also states that health care is free to private initiative, through so-called "private health insurance". In this mode, the beneficiaries pay a pre monthly payment with own resources or from your employer, to the providers of private health plans, for healthcare, in accordance with the parameters established in the contract and the specific regulations. The sector is regulated by the National Health Agency (ANS).

Private sector data plans health of Brazil
Over the past decades there has been an increase in demand for private health plans in Brazil. This move coincided with the epidemiological and demographic transition in the country and deepened with the underfunding of public health and the granting of tax incentives by Government. Adding to this, all companies with 30 or more employees must have their own medical service, provided in most cases by a third party provider. In December 2014, there were 1,425 operators in action and more than 72.2 million insurance beneficiaries in private health plans. The services rendered to beneficiaries, they are by means of more than 117,000 establishments of health.

Standard for Supplementary Health Information Exchange - Standard TISS
As a manner to optimize the sector management, in 2005 the ANS established the Standard for Exchange of Information on Health Insurance (TISS). The structure and the improvement of the TISS are defined by consensus on the Standardization of Information in Health Insurance Committee (COPISS), composed of representatives of the agents operating in the private health insurance sector. The exchange of electronic messages uses the International Classification of Diseases version 10 (ICD-10) and the United Terminology for Supplementary Health (TUSS) to identify events and assistance items. The TUSS has 109,640 terms related to events and assistance items. The TISS is organized into five components: 1) Organizational; 2) Content and structure; 3) Concepts of Representation in Health; 4) Security and Privacy; 5) Communication1. With regard to security and privacy, TISS provides for the adoption of digital certificate with SSL or TLS cryptographic protocol, encrypting at least 128 bits, and authentication HASH MD-5 algorithm. The TISS also defines the content and structure of the mandatory electronic messages, defined using the Extensible Markup Language (XML). The TISS is a mandatory standard for the exchange of electronic information between players in the sector, and in September 2014 it became mandatory that the information exchanged with other agents using the TISS being transferred to the ANS, composing an important database of standardized and individualized records in the context of the future Electronic Health Record project at the national level.

Conclusion
Thus was formed wide range of individualized information of the beneficiaries of private health plans in Brazil, reaching the maximum level of disaggregation. This information will subsidize research, management, evaluation and financial monitoring and assistance of operating private health plans. In addition, standardization and the functional and semantic interoperability of health information promoted by TISS collaborate to forming perspective of the Electronic Health Record at the national level.

Converting the Foundational Model of Anatomy to OWL 2

Landon T. Detwiler, MS\textsuperscript{1}, Jose L.V. Mejino, PhD\textsuperscript{1}, James F. Brinkley, MD, PhD\textsuperscript{1,2,3}

\textsuperscript{1}Departments of Biological Structure, \textsuperscript{2}Computer Science and Engineering, \textsuperscript{3}Biomedical Informatics and Medical Education, University of Washington, Seattle, WA

In this poster we describe the conversion of the Foundational Model of Anatomy (FMA) and the Ontology of Craniofacial Development and Malformation (OCDM) from the Protégé Frames knowledge representation language to OWL 2 (hereafter referred to as OWL). We describe the conversion goals and methodology. Equally importantly, we note what we did not try and accomplish. This conversion is a first step towards tool compatibility, ontology interoperability, and understanding the gains and compromises of such a translation.

The Foundational Model of Anatomy (FMA) (1) is an ontology that is becoming the reference standard for anatomy. To-date the FMA has been represented in Protégé Frames. Although Frames was the representation of choice when we began the FMA project over 15 years ago, the current preferred representation is OWL. Although the conversion of the FMA into OWL has been attempted several times prior, previous efforts were either incomplete, did not meet FMA requirements, or were simply unavailable to the FMA developers. Hence, we implemented our own conversion utility. We have used this tool to convert the FMA into OWL. We are now using the new, converted, FMA in OWL for all new content development.

Our overall conversion approach is implemented as a configurable Java utility. This approach is potentially generalizable to other Frames-based ontologies, which we have partially verified by using it not only to convert the FMA, but also to convert our Ontology of Craniofacial Development and Malformation (OCDM) (2).

The process begins by first converting Frames classes to OWL classes, assigning IRI’s based on existing ontology IDs (FMAID in the case of the FMA) or via an ID generator, and rdfs:labels based on the existing preferred terms. Default slot and slot value conversion strategies are based on value type. These defaults are modifiable via configuration files. Specific example conversion strategies will be described in the poster.

Our primary goals were 1) to capture all or as much as possible of the information in the Frames version, and 2) to make the FMA available as quickly as possible to ontology developers and users. Thus, in the interest of expediency, not all potential improvements were addressed. Finding errors that were not flagged in the Frames version was not a part of this conversion. Additionally, fixing logical inconsistencies or otherwise optimizing the resulting ontology for reasoning is left as a post-conversion task. We expect that these issues will be resolved over time either by ourselves or by other ontology experts, using our converted copy as the starting point.

Because of the fundamental nature of anatomy, and because of the widespread adoption of FMA content by other ontologies and terminologies, the FMA is already an important factor in organizing biomedical data and knowledge. By converting the FMA to the standard representation promoted by the semantic web we ensure that the FMA can become an even more important contributor to the growing worldwide knowledge network in biomedicine.

The conversion code, as well as converted copies of the FMA and the OCDM are available for download.

Predicting the Factors of Improvement of Health Status of Home Health Care Patients: A Holistic Data Mining Approach

Sanjoy Dey, PhD-C²; Katherine Hauwiller²; Pranjul Yadav, MS²; Michael Steinbach, PhD²; György J. Simon, PhD³; Vipin Kumar, PhD²; Connie W. Delaney, PhD, RN, FAAN, FACMI¹; Bonnie L. Westra, PhD, RN, FAAN, FACMI¹,³

¹School of Nursing, ²Department of Computer Science & Engineering, ³Institute for Health Informatics, University of Minnesota.

Introduction
Home health care (HHC) agencies provide health care services at home for patients who need prolonged cares such as seniors, pediatric clients, post-hospital surveillances and thus, can potentially avoid unnecessary hospitalization. To improve the efficiency, patient’s safety, and timeliness of the needed care, Centers for Medicare & Medicaid Services (CMS) has been collecting and reporting the performance data by HHCs electronically through a standardized tool called Outcome and Assessment Information Set (OASIS) since 1999. Mining significant factors and support system characteristics that can lead to the improvement of the overall health of HHC patients is an important research question. However, most of the existing studies use one variable at a time as the potential outcome of the improvement of the health status, and thus miss any potential relationships present among the multiple outcome variables. The goal of this study is to analyze all such potential outcome variables in together to assess the improvement of the overall health of the HHC patients holistically and thus, it can unravel potential relationships present not only among the outcome variables and but also with their underlying associated factors.

Methods
After IRB approval, analysis was performed on large EHRs collected by 581 CMS-certified HHC agencies between October 1, 2009 and December 31, 2010. The dataset contains records of N=270,634 patients in OASIS data format (as described in a previous study [1]) at two different times: one during admission and one during discharge. Both of the records contain demographic, patient history information, high risk factors, living arrangements and caregiver support, health status (e.g., sensory, integument, respiratory, emotional, cognitive, and behavioral), activities of daily living (ADLs) and instrumental ADL (IADLs) and medication management. All of these variables are treated as input to the model. After several stages of preprocessing, 41 binary outcome variables are created to represent the improvement of health status from admission to discharge from HHC. To enhance the interpretability of the model, we further group the 41 outcome variables into eight higher-level groups by summing up the constituent variables of each group. So, each of the eight outcome variables becomes a count variable representing how many of the constituent variables improve. Then, a two-step framework of multi-level learning framework proposed in [2] is used. First, Poisson regression model is used for each of the eight groups independently. Second, each of the outcome groups is relearned, but the prediction obtained from the other seven variables is included as predictors in addition to other generic predictors. This step will elucidate any potential relationships present among the eight variables into the final model. In each of this step, L₁ regularization is performed to select the most predictive factors simultaneously.

Results/Discussion
Preliminary analysis showed that the predictive models had good predictive power, which are far beyond the random model for each of the eight outcomes as shown in the above Figure. In each of the eight outcomes, significant factors obtained from multi-level method were analysed for clinical interpretation. Most of the variables either have been reported in earlier studies or show interesting novel associations. For example, improvement of depression occurs mostly for the patients who were depressed during admission, but did not receive psychiatric nursing and have no drug dependencies. More such associations between the predictors and outcome variables and relationships among the outcome variables are reported.

Improving Vaccine-Preventable Disease Reporting through Health Information Exchange

Brian E. Dixon, MPA, PhD1,2,3, P. Joseph Gibson, PhD1,4, Shaun J. Grannis, MD, MS2,5
1IU Richard M. Fairbanks School of Public Health, Indianapolis, IN; 2Regenstrief Institute Center for Biomedical Informatics, Indianapolis, IN; 3Center for Health Information and Communication, Health Services Research & Development Service, Veterans Health Administration, U.S. Department of Veterans Affairs; 4Marion County Public Health Department, Indianapolis, IN; 5Indiana University School of Medicine, Indianapolis, IN

Introduction
Vaccine preventable disease (VPD) outbreaks require immediate, effective response. Although clinical providers are legally obligated to report VPD cases under state law, provider reporting is frequently incomplete, error-prone, and delayed. We seek to explore whether an intervention, aimed at providers and delivered electronically through a health information exchange (HIE), can improve VPD reporting rates as well as how such an intervention can be implemented in an integrated infrastructure that includes heterogeneous electronic health record (EHR) systems.

Methods
We are implementing an intervention designed to pre-populate the official state health department VPD reporting form with patient demographics, lab results, and provider information available from EHR system messages routinely captured in a regional HIE. The pre-populated form will be delivered electronically to providers via fax, an EHR system, or HIE-provided inbox based on clinic-preferred workflow. Prior to deploying the intervention, we gathered baseline reporting information from fax, paper, and electronic reports that constitute a reported case and were submitted by both providers and labs to a local health department. We measured the completeness of key reporting data elements separately for paper, fax, and electronic reports, stratifying by report type. We also calculated reporting rates and examined the results stratified by clinical source, disease and report type.

Population Studied
The Marion County Public Health Department (MCPHD) serves a population of 928,000 individuals living in 396 square miles. More than one-quarter of residents (28%) are African American and 10% are Hispanic or Latino.

Results
We collected 4,135 reports (documents) submitted to public health for 3,556 cases of Hepatitis B. Completeness of data elements varied by report type: data element completeness for lab reports averaged 67.6% with a range from 21.9% to 100% (except ethnicity which is less than 1%), while data element completeness for provider reports averaged 64.9% with a range from 20.8% to 100%. Lab report completeness was higher than corresponding provider report fields for 8 of 15 critical fields. Physicians reported in less than 1% of the cases reported by labs, and all physician-reported cases were also reported by labs. We have collected more than 600 additional reports for other VPD cases, including measles, mumps, chickenpox, and pertussis. Analysis of completeness, timeliness, and reporting rates for these diseases is ongoing. We anticipate the analysis will be completed before fall, making the preliminary results available for the poster along with those for HBV.

Conclusion
The rise of EHR and electronic lab reporting (ELR) reporting capacity among health departments due to meaningful use (MU) may improve assessment of disease incidence and burden. Yet data completeness remains problematic for both lab and provider reports, frequently necessitating calls to health systems to investigate and respond to VPD cases. Health information exchanges may help support more complete capture of information while reducing burden for both clinical and public health organizations.
Patient Centered Medical Home (PCMH) Team Huddle Tool

Nhan V. Do, MD¹, Terry J. Newton, MD¹, Rick L. Barnhill BS², Eric A. Shry MD²
¹Office of the Surgeon General, US Army, Falls Church, VA; ²Madigan Army Medical Center, Tacoma, WA

Abstract
The PCMH care model centers on a team care approach. We developed the PCMH Team Huddle Tool (PTHT) to augment the functionality of our EHR to support the delivery of actionable information in the workflow of PCMH care teams. Preliminary results over a 12 month period post implementation show higher percentage rates in 6 HEDIS quality measures in the Army’s Medical Treatment Facilities (MTF) with PTHT than in MTFs without PTHT.

Introduction
The Army has adopted the Patient Centered Medical Home (PCMH) model to improve access, care management, and health outcomes. Successful implementation of the PCMH model centers on a team care approach, and each morning the Army PCMH team “huddles” to coordinate the care for the medical home patients. Prior attempts to meet the information needs of the PCMH team have been either manual aggregation of patient data from up to 5 separate sources or automation through complex electronic dashboards designed by the enterprise with limited user acceptance. Our objective is to augment our Electronic Health Record (EHR) with the development of a health information technology tool that provides rapid access to actionable information within the PCMH team’s workflow. As observed by Bates and Bitton, current EHRs do not have the full functionalities to support the PCMH model of care¹.

System Description
The PCMH Team Huddle Tool (PTHT) was developed at Madigan Army Medical Center through an agile process with close collaboration with subject matter experts from PCMH teams. Workflow analysis and usability studies were conducted as part of the development process. The tool offers multiple functionalities to coordinate the care of the medical home patients such as identifying patients who are transitioning from the Emergency Department or from a hospitalization, flagging overdue preventive services, redirecting appointments to better match patients to their assigned primary care providers, quick look up of clinical data for decision making, and monitoring of performance measures. From June 2013 to May 2014, the PTHT was deployed to 14 MTFs in the Army’s Western Regional Medical Command with 3 MTFs remaining on the deployment schedule. Using the natural experiment setting from the deployment schedule, we compared 4 Healthcare Effectiveness Data and Information Set (HEDIS) screening measures (screening for breast cancer, colorectal cancer, chlamydia, and LDL in diabetic patients) and two HEDIS performance goals (HgbA1c, LDL) between the MTFs with PTHT and those without PTHT.

Results
Achieving HgbA1c goal of < 9% and LDL goal of < 100 mg/dL in diabetic patients were 8.0% (p < 0.0001) and 4.3% (p=0.02) higher respectively in MTFs with PTHT than MTFs without PTHT. Achieving screening goal for breast cancer, colorectal cancer, chlamydia, and diabetics’ LDL were 9.2% (p <0.0001), 5.1% (p <0.0001), 2.2% (p =0.006), and 5.9% (p<0.0001) higher respectively in MTFs with PTHT than MTFs without PTHT.

Conclusion
A well designed information technology tool to serve up actionable information to support a team based workflow has great potential to advance the PCMH model of care. Our preliminary results showed significant differences in 6 HEDIS quality measures over 12 months of implementation of the PCMH Team Huddle Tool, and we are expanding our evaluation of the tool with additional HEDIS measures and additional facilities through an observational study design.

Automatic Phone and Text Message Reminders to Increase Patient Completion of Outpatient Laboratory Testing

Trygve Dolber, MD,1 and David C Kaelber, MD, PhD, MPH1,2

1School of Medicine, 2Center for Clinical Informatics Research and Education, The MetroHealth System, Case Western Reserve University, Cleveland, OH

Abstract
Laboratory evaluation is a significant part of patient care. In many healthcare systems, labs are not collected at the point of care, but rather are ordered in clinic with patient instructions to go to a different location. Therefore, many ordered labs may not be collected. We implemented an automated phone and text message reminders system that increased lab collection over 250%. Phone messages were more effective than text messages.

Background
The MetroHealth System is a large, safety-net, integrated healthcare delivery network including a tertiary care medical center and over 20 satellite clinics in northeast OH, with over 1,000,000 outpatient visit and millions of lab tests ordered annually. Most clinics do not collect labs at the point of care, rather ordering labs and instructing patients to go to central locations for lab collection. In 2013 only 8% of patients with outpatient laboratory tests ordered presented to the lab in the final week before their orders expired (1 month after ordering). We implemented automated phone and text reminders to help with lab collection.

Methods
Using our Epic electronic health record (Epic Systems, Verona WI) we identify patients who have had labs ordered but the specimen is still not collected after 3 weeks. We provide this information to a third-party messaging vendor (TeleVox) which sends automated text and phone reminders to these patients in the beginning of the 4th week. Text messages are sent to those patients with a textable phone. Otherwise a phone message was sent. We randomly selected 100 patients (50 phone and 50 text) each from four different two-week periods between 10/14 and 1/15 to determine effectiveness of the messages sent at the beginning of the 4th week on having the lab collected by the end of that week.

Results
Automated messaging results appears in Figure 1. Both verbal phone (37% average effectiveness) and text (29% average effectiveness) messaging (33% overall average effectiveness) were much more effective than the baseline 8% average effectiveness without messaging (p<.05), but were not statistically different (p=0.16).

Discussion
Most evidence suggests that health care-related text message reminders are equally effective as verbal phone call messages,1 but these findings may not apply to a low-income urban setting in the United States. Mobile phones are widely used in low-income communities and may be more stable than landlines,2 and so text messaging could represent a more direct way to reach many patients.

Conclusion
Automated phone and text messages for ordered labs significantly improve laboratory completion.

Evaluating Mobile Information Use: Moving from Access to Interpretation and Application

Glynda J. Doyle, RN, MSN1, Karen Furlong, RN, MN, PhD2, Loretta Secco, RN, BScN, MN, PhD2, Judy Bailey, RN, BScN, MN3, Barbara Jamieson, RN, BScN, MN3, Wayne Hansen, EET, BA, MIDST2 & Robert Pafford, BA, Bed, Med2

1 British Columbia Institute of Technology, BC, Canada; 2University of New Brunswick, NS, Canada; 3Cape Breton University, NS, Canada

Abstract

Integration of mobile information supports in nursing curricula is assumed to promote computer and informatics competencies, however it is unclear whether this education strategy promotes evidence-based practice. Since mobile information practices are poorly understood, researchers from three Canadian nursing programs surveyed students and faculty to determine their use of, and attitudes toward, mobile information supports within classroom, laboratory and clinical settings.

Purpose

This multi-site exploratory study evaluated student and faculty perceptions and use of mobile devices and information software programs called Nursing Central © (NC) ™ and uCentral ™ (UC) from Unbound Medicine. With the introduction of entry-to-practice informatics competencies for Registered Nurses1, nurse educators are seeking strategies to foster development of student competency within the rapidly evolving field of informatics. Researchers evaluated student and faculty use of mobile devices and their how information resources supported learning.

Methodology

Data were collected with two online (Qualtrics) surveys designed to measure faculty and student perspectives and use of electronic information accessed via Unbound Medicine software programs. The sample consisted of students and faculty from three Canadian undergraduate nursing programs at six sites where Unbound Medicine products are used. Quantitative analysis included (a) psychometric assessment and determination of validity and reliability of a new Mobile Information Support Evaluation Tool (MISET) with three subscales: usefulness/helpfulness, information literacy support, and use for evidence-based sources, and (b) descriptive and inferential analysis of MISET data. Researchers explored participants’ descriptions of their use, application, and evaluation of NC/UC as teaching and learning resources. Qualitative content from survey text boxes were analyzed for common themes. Researchers were interested in understanding faculty and students’ use and evaluation of mobile within various teaching and learning settings.

Findings

This poster will present the MISET quantitative findings, comparisons across universities, qualitative themes, and triangulation of qualitative and quantitative results. Two emergent themes relevant for nursing education, learning to use mobile resources and student learning outcomes with the use of mobile resources, will be addressed.

Conclusion

The main recommendation emerging from this study is that nurse educators make a paradigm shift away from using mobile technologies to merely support task-oriented, student information seeking, and focus on mobile information technologies to support application of relevant health information to achieve quality patient care and advance nursing knowledge.

Using social media data to analyze patient satisfaction of health care facilities

Katherine Doyon BSN, M.S.1, Qing Zeng-Treitler Ph.D1,2, Rebecca Morris MPH1, Catherine Arnott Smith Ph.D3, Yijun Shao PhD1,2

1University of Utah, 2Salt Lake City Veteran Affairs Hospital, 3University Wisconsin-Madison

Abstract: Patient satisfaction has frequently been used as an indicator of health care quality, often determined through surveys. In this study we analyzed social media containing open-ended survey questions to assess patient satisfaction in clinics, hospitals, and other health care facilities in nine regions across the country to identify themes not surveyed in typical health care questionnaires. Our analysis indicated that the majority of patient’s reviews comment on getting care, personal attributes of staff, and the facility.

Introduction: New health care reforms have placed an emphasis on patient satisfaction, often assessed through surveys. Traditional surveys employ Likert scales and multiple choice responses to assess standardized questions. We believe this limits the amount and type of data captured. Our analysis of patient satisfaction differs in that we analyzed open-ended patient comments captured through social media. We analyzed 771 google + reviews from nine different regions across the country to assess the major themes and quantify the primary area of concern for patients and family members.

Methods: 771 Google+ reviews of medical health care facilities were collected from the following 9 regions of the United States: East North Central, East South Central, Mountain, New England, Middle Atlantic, Pacific, South Atlantic, West North Central, and West South Central. This methodology allowed us to have a national sample without any regional bias. These facilities ranged from large academic centers to single provider offices, and were staffed by a variety of physicians from general practitioners to specialists.

Nvivo: A thematic analysis was conducted to identify factors contributing to patient satisfaction. The initial codes were developed using measures found in the Health Resources and Services Administration (HRSA) Patient Satisfaction Survey. QSR NVivo 10 software (QSR International, 2008) was used for the thematic analysis. In addition to the thematic review, an automated topic modeling analysis was conducted. Prevalence of each node was calculated using matrix coding queries of each parent node in each region.

Word Cloud: A word cloud depicting the prevalence of the words in the google + reviews was constructed by the following formula:

\[
\frac{\sum_w c_t_a(w) \times c_t_b(w)}{\sqrt{\sum_w c_t_a(w)^2} \times \sqrt{\sum_w c_t_b(w)^2}}
\]

Results: Overall 771 reviews were coded for analysis. The majority of reviews contain a comment about the provider (41%) followed by aspects of getting care (37%) such as getting an appointment and time spent in the waiting room. Patients were also concerned about the facility itself (23%) and the outcome of the experience (19%).

Conclusion: Our preliminary results indicate that patients comment on aspects of their health care experience outside the typical health care questionnaire. The analysis of the data identified a number of additional topics that contribute to patient satisfaction, not covered by the HRSA Patient Satisfaction Survey.
A Comparative Analysis of Factors for Predicting Inpatient Length of Stay for Colorectal Cancer Patients

1Prerna Dua, 2Akhila Reddy, 3Pradeep Chowriappa

1Department of Health Informatics and Information Management, 2,3Department of Computer Science
Louisiana Tech University, Ruston LA 71272
*prerna@latech.edu

INTRODUCTION

Colorectal cancer is the third most commonly diagnosed cancer and second leading cause of cancer deaths in the United States. Early diagnosis and treatment accordingly can improve the chances of survivability of the patients. There have been developments in treatment of colorectal cancer, such as greater surgical specialization and wider use of laparoscopic procedures. However, these procedures add to the length of the stay of the patient. The model employed in this research attempts to understand the factors that lead to the increased length of stay.

Survival analysis is a collection of statistical methods that deals with the analysis of time duration to until the event of interest occurs. Cox proportional hazard model (also referred as cox model) is a type of semi parametric model that is considered to be the most applicable model to analyze survival data. The main purpose of this research is to illustrate the use of Cox proportional hazard model and to identify the significant features that influence the length of stay of colon cancer patients in the hospitals.

METHODOLOGY

The framework consists of the following major computational steps. (1) In data pre-processing a) Remove outliers and extreme values b) Handle missing data c) Data transformations (2) In Cox model building, we identify the significant features that influence the length of stay of colon cancer patients.

We analyzed the colon cancer data available from Statewide Planning and Research Cooperative System (SPARCS) database. It contains discharge level detail on patient characteristics, diagnoses, treatments, services, outpatient discharge details in New York State from 2009-2012 years. The dataset contains 31 attributes and 10567 records. The explanatory variables, which are assumed to influence the length of stay of colon cancer patients, are shown in the table 1. The response variable is the time until the occurrence of event or the time between two events in days, months, minutes, and seconds. The response variable should contain continuous and interval level data.

EXPERIMENTAL RESULTS

The highest numbers of admissions were for the patients (with colon cancer) who are 70 or older and are lowest for the patients aged 0 to 17 years. There was more number of admissions for white, when compared to African american or Hispanic people. The length of stay was longer for the patients aged above 70 when compared to those aged 0 to 17 years. The patients those aged 30 to 69 are 81% less likely to be discharged earlier from the hospital (HR=0.19, p=0.004). There was a significant increase in the LOS as the increase in the age. There were no significant variations in LOS based on gender, ethnicity, and race.

The highest number of admissions was recorded for the patients who were admitted as elective while the lowest was for the patients admitted as urgent. There were more number of admissions on Tuesday and even most of the patients discharged on Tuesdays. Of all the admissions 55% of the patients were discharged to home, 13% of the patients were transferred to skilled nursing home.

The length of stay was shorter for the patients who had emergency admissions (HR=1.064, P=0.044) when compared to those who had electives and are 0.06% more likely to be discharged earlier from the hospital. The Length of stay was significantly shorter for the patients who were discharged on Thursday, Monday, and Tuesday (HR=1.155, P=0.002; HR=1.140, P=0.003; HR=1.090, P=0.056) when compared to those discharged on Friday and are 15%, 14, and 9% more likely to be discharged earlier from the hospital. There were no significant variations in LOS based on patient disposition, admit day of the week. This was probably because less diagnostic procedures were performed as hospital staffing is reduced on weekends. Also, fewer supervisors are present in the hospitals on weekends. Similar results were found in two other studies that were used as a reference.

The major proportion (82%) of the admissions was for the patients who had undergone surgery and also highest number of admissions was for the patients who do not need immediate medical attention. The LOS was significantly shorter for the patients who required immediate medical attention (HR=1.081,P=0.013) and are 8% more likely to be discharged earlier from the hospital when compared to those who do not need. There were no significant variations in the LOS based on severity of illness, risk of mortality, medical and surgical description.
Initial Approach to Creating an Interactive User Interface Design Tool to Enhance User-Centered Design

Kevin R. Dufendach, MD, FAAP; Kim M. Unertl, PhD, MS; Christoph U. Lehmann, MD, FAAP, FACMI
Vanderbilt University, Nashville, TN

Introduction

Visual interfaces in health information technology are often designed by a small group of experts or modeled after existing interfaces. User-centered and participatory approaches to design have the potential to improve satisfaction and the fit between technology and user needs. Including end-users from the start of the design process requires obtaining input from a large number of individuals, which may be logistically impractical. We present a novel approach to collecting user input into health information technology design.

Methods

We developed an interactive graphical user interface design tool to capture feedback from a large number of end-users quickly and easily (Figure). Using a drag-and-drop web-based application, users are able to select data elements, modify them, and customize a user interface quickly and easily.

The design team initially prepares the interface context and customizable elements using a combination of JSON, CSS, and HTML. Users then select which elements they want displayed, position them appropriately, and specify preferences on how they should be formatted. These preferences are reflected immediately on the screen. If desired, the design team can prepare clinical scenarios to give users direct feedback on how their preferences would look under various conditions. Once users are satisfied with the selected elements, display, and location on the screen, they submit their finished products, allowing the design team to aggregate feedback across users and evaluate potential interface approaches.

Application

The first use case planned for study using this tool is a neonatal intensive care unit physician handoff tool, which we will examine in a multi-site study. Neonatal clinicians will select specific elements and format them to their preferences. For example, after selecting “coagulation labs” to appear, the clinician can then format them either as a stick figure or in a list form. Aggregating these data will allow us to delineate the specific information needs from a large number of users.
Regenstrief ePRO: A Rule-Based Platform for Capturing Targeted Patient-Reported Outcomes

Jon Duke, MD, MS1, Daniel J. Vreeman, DPT, MS2,3, Jeremy Leventhal, MS1, Chen Wen, MS1, Katie Allen, BS1, David Haggstrom, MD, MAS1,2,3

1 Regenstrief Institute, Inc., Indianapolis, Indiana
2 Indiana University School of Medicine, Indianapolis, Indiana
3 Veterans Health Administration, Health Services Research and Development Service, Indianapolis, Indiana

Introduction
Self-reported health assessments have received increased attention over the past decade. These appraisals of behaviors, clinical outcomes, and day-to-day health characteristics are now increasingly incorporated into patient care, quality improvement, and research activities. With advancements in technology, shifts have also occurred in creating electronic tools and data systems for capturing Patient Reported Outcomes (PRO). Next-generation electronic PRO (ePRO) systems should incorporate highly targeted delivery of questions to patients based on demographic, clinical (e.g., disease, medications), and behavioral characteristics. The routine, efficient capture of this information could make a significant contribution to patient care and advance research for many disease states. However, connecting disparate data sources, tailoring questions, and capturing patient responses in a usable fashion each present their own challenge.

Methods
Our team set out to develop a comprehensive ePRO tool that was flexible, scalable, and generalizable. This tool would generate and store PRO measures on an unlimited variety of topics. Additionally, the tool would facilitate downstream delivery of responses to the electronic health records, allowing the patient information to be available at the point of care.

Results
A multi-component platform was developed that includes an expandable bank of questions stored in a common data format, a tool for question selection and ad hoc question creation, and an interface for patient data collection. LOINC® (http://loinc.org), a code system for tests, measurements, and observations, was selected to address the standardization of question definition. The platform included integration with the Regenstrief Rule Authoring and Validation Environment (RAVE) for question selection and ad hoc question creation. OpenMRS® (http://openmrs.org), a web-based, medical record software platform, was leveraged as the question delivery mechanism for data capture from patients. The resulting multi-component platform allows user access on a tablet device via the Internet. At the triggering event of a patient check-in (A/D/T message, appointment) the system checks for questions applicable to this patient that have been queued into the “Question Table.” Questions are added to the queue based on demographics and medical record information. Questions can vary in type (e.g. free text, yes/no, multiple choice, scale) and skip logic is included in the overall design. The questions are delivered through an OpenMRS module and are presented to the patient via the tablet. The tool requests the patient confirm their identity prior to displaying the tailored questions. The tool stores patient responses into a database, including the question status (asked/answered), the question response, associated LOINC code, date created, and applicable identifier for future matching. Patient responses are then propagated to the Indiana Network for Patient Care (INPC), a regional health information exchange, for downstream uses.

Conclusion
By utilizing widely adopted standards and open-source web-based applications, we have created a tool that is generalizable to many technology environments. By developing a highly customizable system with the ability to tailor questions based upon disease state or demographics, this ePRO demonstration has created an infrastructure to enable the collection of critical information that will inform both patient care and research. We have proven the feasibility of building a highly adaptable tool and have now begun usability testing in the clinical environment.
Research Objective: Current methods for researchers to obtain patient consent for the authorized use of their data can be inefficient and resource intensive. For this study we conducted a scan of new approaches for obtaining and maintaining patient consent for the authorized use of individually identifiable data for research. This study is part of a larger initiative to inform the development of data capacity for patient-centered outcomes research (PCOR).

Study Design: Findings were informed by a review of relevant literature, thirteen qualitative discussions with key informants, and an in-person expert meeting with twenty-two participants. Our informants for the qualitative discussions and in-person meeting included researchers at patient-powered research networks (PPRNs), academic researchers, federal representatives, private payers, industry experts, and PCORI representatives.

Principal Findings

- Emerging standards for facilitating the sharing of patient authorization include:
  - The Direct protocol, which is a "push" mechanism for securely exchanging data.
  - OAuth, an open standard for authorization that manages identities and would make the request of the data holder on behalf of the patient to share his/her data with a third party.

- Researchers proposed novel approaches for obtaining consent, leveraging technology. These include:
  - "Modular consent," which requires the patient to first provide general consent to a study and then a second level of consent as related sub-studies arise.
  - "Portable consent," which instantiates the concept of "meaningful consent," whereby the consent process and research purpose are clear to the participant. In order to do this, researchers would use software applications with enhanced user interface features that walk the patient through the consent process to help the participant understand what he/she is consenting to.

- Managing Patient Consent. A third party, such as a PPRN, would create “registries” of patients who are interested in and willing to provide data for research on an ongoing basis. This third party would be: 1) responsible for contacting the prospective participants and obtaining documentation of their consent; 2) responsible for building and maintaining the registries of patients who have consented to use of their data for research purposes; and 3) responsible for sharing the registry with potential data holders.

- Consumer-mediated exchange. A patient would have the ability to download his/her medical data to his/her mobile device and push his/her data to a third party (e.g., research organization). This approach could be supported by BlueButton platforms such as the iBlueButton app.

Conclusions: Advances in technology enable new and innovative ways to manage and share patient consent. Institutional Review Boards could assess these methods to make sure they are appropriate in the context of specific proposed studies. These innovative methods for obtaining and managing patient consent have the potential to facilitate the secure sharing of data for PCOR with patient preferences in mind.

Implications for Policy or Practice: Findings from this qualitative data collection could potentially inform investments in PCOR data infrastructure.

A Six State Review of Grantees’ Experiences with the State HIE Program

Prashila Dullabh, MD¹, Petry S. Ubri¹, Lauren Hovey, MA¹
¹NORC at the University of Chicago, Bethesda, MD

Research Objective
The State Health Information Exchange (HIE) Program aimed to expand the secure movement of electronic health information. We conducted in-depth case studies to assess grantees’ experiences implementing the program, including progress, changes in strategies, challenges, and lessons learned.

Study Design
We selected states with varied programmatic approaches, state contextual factors, and HIE progress, gauged using key outcome measures in clinical lab exchange, care summary exchange, and e-prescribing. We used e-prescribing data from Surescripts, and survey data from the American Hospital Association (AHA) Health IT Supplement and the National Electronic Health Record Survey (NEHRS). From March-May 2014, we conducted site visits and semi-structured discussions with over 108 HIE stakeholders.

Principal Findings

- Grantees pursued dual-pronged strategies to enabling directed and query-based exchange, providing services like care summary and lab results exchange, public health reporting, and admission, discharge, transfer (ADT) alerts.
- Grantees selected federated or centralized infrastructure to meet local stakeholders’ needs and based on the state’s proliferation of HIE organizations.
- Enablers included policy and regulatory levers associated with the Affordable Care Act and payment reform, state and legislative actions, and stakeholder engagement.
- Challenges and lessons learned:
  - Set tangible, intermediate processes and goals that allow for course corrections.
  - Large health systems, that delivered participants and data in some markets and were competitors in others, influenced the uptake of grantees services.
  - Vendor limitations caused some grantees to shift to a best-of-breed approach.
  - Many grantees looked to ongoing development and adoption of standards in the long-term while building data translation capabilities in-house in the short term for interoperability and data capture and quality issues.
- Many grantees sustainable plans focus on Stage 2 meaningful use exchange requirements and aligning service offerings with payment reform priorities.
- Stakeholders credit the program with raising awareness of HIE; facilitating the breaking down of silos; and establishing foundational elements necessary for exchange. Though it is too early to tell the long-term impact, stakeholders felt HIE’s value would increase over time with support from new care and payment models.

Conclusions
Grantees made progress garnering stakeholder trust and participation, expanding HIE service options, and addressing persistent HIE barriers. Notable lessons learned include building exchange capabilities incrementally, selling the HIE concept to big players, and resolving incompatibilities with HIE vendors.

Implications for Policy, Delivery or Practice
States play important roles in leadership and coordination, particularly convening stakeholders, policy development, and needs assessment. In addition, strong, ongoing support related to standards and interoperability is needed; a provider- or federal-led effort to obtain vendor buy-in for HIE goals may be warranted to achieve interoperability. There is also a need to assess how technical solutions evolve in different markets, develop, and disseminate best practices, and develop governance and oversight requirements. Organizations should also monitor sustainability findings and best practices from existing initiatives leveraging pay-for-performance models.
User Adherence to a Web-Based Application for Youth with mild TBI

Jenna R Dyas, BS, Judith W Dexheimer, PhD, Brad Kurowski, MD, MS, Shari L Wade, PhD, Nanhua Zhang, PhD, Lynn Babcock, MD, MS
Cincinnati Children’s Hospital Medical Center, Cincinnati, OH

Introduction
Mild traumatic brain injury (mTBI) is one of the most common injuries sustained by youth in the US accounting for 500,000 emergency department visits annually. Despite the prevalence, there are limited treatments available to help patients cope with symptoms such as fatigue and impaired concentration. We developed a novel web-based intervention that included guidance, individualized symptom management, and evidence-based cognitive-behavioral coping strategies: Self-Monitoring, Activity-Restriction and Relaxation Treatment (SMART). The objective of this study was to evaluate participant adherence to the SMART program.

Data and Methods
All patients 11 to 17 years of age presenting to the pediatric emergency department (ED) from 10/2013 to 7/2014 who presented within 96 hours of sustaining an mTBI were eligible. Participants were asked to log into SMART daily and record their symptoms using the Post-Concussion Symptom Scale (PCSS). Participants also completed web-based surveys assessing symptoms, using the Health and Behavior Inventory (HBI), at baseline in the ED and at 1, 2 and 4 weeks post-injury. Participants were contacted by a research coordinator via their preferred method, (e.g., text) when they were inactive in SMART for more than a few days. Adherence was measured using number of logins and analyzed using descriptive statistics. Participants were considered “completers” if they completed at least one follow-up assessment. The range of usage was correlated using Spearman’s correlation.

Results and Discussion
We enrolled 21 participants and 13 (62%) completed study procedures. Completers and non-completers did not differ with respect to average age (14.3 (SD1.9) vs 15.3 (SD2.4) years), gender (69 vs 63% male), race (100 vs 75% white) or initial symptom burden (24.2 (SD9.9) vs 25.6 (SD13.0)). For completers, the average number of logins per participant was 7 (range: 3-17). The figure shows frequency of logins. Symptoms decreased by 2.2 points each day and only 2 participants (15%) had symptom scores beyond normative values at 2 weeks post-injury. The trend of login frequency decreased similarly but we found no correlation between adherence and HBI or PCSS scores.

Differences in adherence could not be attributed to demographics or symptom burden. The majority of participants were nearly asymptomatic at 2 weeks post-injury; this may have impacted adherence since these participants no longer needed symptom management. For future trials of SMART, confining study procedures to 2 weeks post-injury and employing innovative strategies may ensure good study adherence. Further research could include automated follow-up reminders and more accessible modes of survey delivery, such as a smart phone application.

ABSTRACT
Centralized cardiac monitoring using portable telemetry devices is an important, but costly approach to monitoring at risk patients. Telemetry is highly resource dependent requiring specialized staff and equipment. This safety net is often ordered inappropriately with delays in discontinuation for both adult and non-ICU patients (Bubb, 2011). This in turn creates delays in care for those who most need it.

At our medical center, the decision was made to develop a CPOE orderset with criteria for telemetry placement as algorithmic support for a nurse-driven discontinuation protocol. Analysis of the people, process and technology issues using the sociotechnical model developed by Sittig, et.al. (2010) helped to identify barriers and opportunities for success. This model was selected for its interactive dimensions that lend to improved patient safety. Variations in ordering of telemetry were opportunities for improvement. As nurse driven discontinuation exploration of the socio aspects are critical.

PURPOSE
The purpose of this project was to facilitate discontinuation of telemetry in the adult inpatient setting by implementing a nursing driven protocol using an eight dimensional sociotechnical model as a guide and to minimize inappropriate ordering of telemetry.

SOCIOTECHNICAL MODEL
- Hardware and Software- Multiple order sets, decision support tools for telemetry order entry and discontinuation replaced a single solution.
- Clinical Content- Develop protocols using AHA criteria in ordersets instead of local preference (Drew et al., 2004).
- Human- Computer Interface- Clinical workflow analysis was conducted and a clinical decision support tool was modified for ordering telemetry.
- People- Identified as a rapid cycle improvement project by administrative leadership. Developed protocols that work with physicians, nurse practitioners, nurses, the leader-manager and culture. Interpersonal factors considered included values, culture, and experience.
- Workflow and Communication- Evaluated all the ways that patients were identified as needing telemetry such as ED page, consults, direct evaluations, and referrals.
- Organizational Policies, Procedures- Adult and Pediatrics policies examined for consistency Telemetry guidelines were created using the AHA criteria for patient selection.
- External Rules, Regulations, and Pressures- Local Nurse scope of practice evaluated.
- System Measurement and Monitoring- Pre-implementation identified patients currently on telemetry inappropriately.

CONCLUSIONS
Criterion based ordering and nurse driven protocols offer opportunity to improve the efficiency and effectiveness of ordered therapies and monitoring. The sociotechnical model was helpful in understanding and planning for the eco-system in which provider order entry and fulfillment exists. The interactive socio and technical dimensions exposed corresponding aspects needed in decision making.

The Evolution of a Clinical Decision Support Request Form

Shirley Xiang Fei RPh, PharmD1, Sharon Bouyer-Ferullo DNP, RN, MHA, CNOR1, Charles Lagor MD, PhD, CPHIMS1, Saverio Maviglia MD, MSc1,2,3, Eileen Yoshida RPh, MBA1

1Clinical Informatics, Partners eCare, Partners Healthcare Systems, Boston, MA, 2Department of General Internal Medicine, Brigham and Women’s Hospital, Boston, MA, 3Harvard Medical School, Boston, MA

Abstract

A large hospital organization transitioned from multiple homegrown systems to one commercial enterprise-wide electronic health record (EHR). A standardized clinical decision support (CDS) request form was developed to capture elements of new and existing requests. The form’s content format was significantly revised and the function was redefined to maintain consistency. Lessons learned include organizing the required elements based on EHR functionality and workflow impact of the request form on different stages of the CDS lifecycle.

Introduction

A large academic hospital organization with seven affiliates decided to transition from multiple home-grown and commercial systems to one commercial EHR. The task to develop a standardized request form that would capture necessary elements of CDS was essential to inventory current state CDS, to migrate current state CDS into the new system, to evaluate new CDS requests and to maintain consistency among CDS of different origins.

Methods

We formed a group of clinical informaticians, knowledge Engineers (KEs), and clinical experts who decided on the necessary data elements for a CDS request form. The initial set of requested data resulted in a seven page Word document with embedded macros. This form was significantly revised several times based upon the feedback from requestors, end-users, application teams, and clinical informatics team members. Revisions were further made based on CDS key element requirements, functional completeness, format and usability. The database where this information was kept also changed during this time. The result for managing requests for CDS interventions become a concise, portable, and useful Excel spreadsheet with the minimally necessary data elements that was easily loaded into an open source content management system (JIRA). This system is the source for requests for CDS new and status updates.

Results

The CDS Request Form evolved from a large multi-purpose Word document into an Excel spreadsheet with more concise data element fields. The spreadsheet includes specific tabs that represent different stages of our CDS lifecycle. We are working toward a requester-facing online form which prompts for all necessary elements of the CDS request without overwhelming the users. The governance involved with the CDS request form request and revisions have a specific process in place set by the CDS Committee.

Conclusion

Our CDS transition process included creating an inventory of current state CDS, the transformation and migration of current state CDS into a new commercial EHR system, as well as tracking and evaluating new CDS requests. Satisfying all these different requirements within the short period of time allocated for the implementation of the new system posed a significant challenge. Another challenge was the relative unfamiliarity with the new system, so requirements remained a moving target. While we are still continuously making improvements to the CDS request process, we have learned many lessons during the evolution of the CDS request form so far. We have learned to organize and frame the required elements based on EHR functionality and workflow; we have also learned the impact of the request form has on different stages of the CDS lifecycle.

Challenges for Residents in Following Instruction in Laparoscopic Surgery

Yuanyuan Feng, MS\textsuperscript{1}; Hamid R. Zahiri, MD\textsuperscript{2}; Helena Mentis, PhD\textsuperscript{1}
\textsuperscript{1}University of Maryland Baltimore County, Baltimore, MD; \textsuperscript{2}Anne Arundel Medical Center, Annapolis, MD

Abstract

Operating room-based training plays an important role in accumulating experiences in laparoscopic surgeries. Efficient trainings depend on residents’ understanding of the instructions given by senior surgeons. However, residents’ difficulties in understanding instructions are often overlooked by training system design. In this study, we focus on the challenges residents have in following instructions during the surgery. Our findings can be used to make recommendations for the design of effective surgical training system and surgical support system.

Introduction

Simulation-based training, which allows residents to accumulate surgical skills outside the operating room, has become mainstream in surgical education. However, in a recent survey on residents’ perceptions of the simulators, the authors found that residents had difficulties in transferring the skills gained from simulators into clinical settings. Operating room (OR)-based training is the core place where, with the guidance of senior surgeons, residents become proficient in applying surgical skills in real cases. The motivation of this study is to understand the challenges residents have in understanding and reacting to the instructions during a laparoscopic surgery, in order to make recommendations for the design of effective surgical training systems and surgical support systems.

Methods

This is a qualitative, exploratory study. Individual semi-structured interviews were conducted with three senior general surgery residents, who have primarily performed at least one laparoscopic surgery. The interview focused on the residents’ physical and cognitive challenges in following the instructions in their laparoscopic surgery.

Findings

A wide variety of intraoperative challenges for residents in following senior surgeons’ instructions were identified. We classified them into two subsets – cognitive challenges and physical challenges. Cognitive challenges include attention distribution, visually mapping instructions on the video and impaired judgment. Residents identified that they had difficulties in properly allocating their attention, in order to listen to the instructions. Sometimes, after receiving an instruction, they had to stop their tasks at hand and shift their attention to actively listen to the senior surgeon. Residents identified high cognitive load in transferring verbal instructions into visual targets on the video. They needed to ask for more explanations of the instructions and even waited for senior surgeons to physically point to the monitor to locate the correct target. In addition, residents reported to have less confidence in performing a laparoscopic surgery, because they perceived that the laparoscopic surgical environment was uncontrolled. They felt uncertain about how to manipulate the instrument, which instrument to use, how to dissect without sensation, and how to coordinate their perception and movement. Their uncertainty and lack of confidence intimidated them in performing a procedure, limited their surgical skills, and impaired their judgment. The physical challenges include unfamiliarity of the tasks and physical fatigue. Residents reported that instructions sometimes included unfamiliar tasks, which they had not prepared. These tasks resulted in awkward movements, which inhibited them to follow the instructions. Further, all of the residents reported that fatigue was one of major challenges for them to follow the instructions. The heavy workload, static postures, eye gaze and accommodating the senior surgeons preferences added physical challenges for residents to follow instructions.

Conclusion

We identified a variety of challenges residents reported in following instructions in a laparoscopic surgery. The findings indicate that for residents to efficiently transfer their surgical skills from the simulators to the OR, the design of both simulation training systems and surgical support systems should be further enhanced. For simulation system designers, it highlights the needs to train residents in how to deal with these challenges and how to transfer their skills under these difficulties. For surgical support system designers, it addresses the needs to support effective communication among surgical team members and to create an operating environment that reduce the level of uncertainty and stress for residents.
Implementing automated delivery of evidence-based medication safety information to the point of care

Joseph Finkelstein, MD, PhD¹, Hayden Z Adams², Qinlang Chen¹, Kuo Lin¹, Carol Friedman, PhD¹

¹Columbia University, New York, NY; ²Stony Brook University, Stony Brook, NY

Introduction

PubMed provides open access to a vast repository of indexed abstracts containing the most recent literature about medication safety. However access to this information at the point care is limited due to time constraints and search skills of providers. An automated tool available as a mobile app or EMR function that is easy to use and that rapidly provides highly relevant safety information can address these barriers.

Methods

NLM APIs and MESH indexing was used to develop specialized medication queries addressing major types of medication safety issues. The ultimate goal is to develop and validate a set of clinical filters which support automated retrieval of medication safety information at the point of care.

Results

The prototype interface is presented in Figure 1. Depending on patient history, information can be provided on possible adverse drug reactions (ADRs) as well as various interactions. Preliminary analysis of medication filters to identify adverse drug reactions demonstrated satisfactory recall and precision. Evaluation of one of the filters demonstrated a recall of 90% and precision of 93% in retrieval of all ADRs associated with a specific medication¹.

Figure 1. Automated extraction of medication safety rules from PubMed.

Grantees’ Lessons Learned in Implementing State HIE Initiatives

Kathryn Fischer, MPH¹, Prashila Dullabh, MD¹, Lauren Hovey, MA¹,
¹NORC at the University of Chicago, Bethesda, MD;

Research Objective

The State Health Information Exchange Cooperative Agreement Program (State HIE Program) was a four-year program under the Office of the National Coordinator for Health Information Technology (ONC) that provided the 56 states and territories with $564 million dollars in funding to invest in HIE solutions. ONC charged states and territories or state designated entities (grantees) with creating or enabling the necessary governance, policies, technical services, business operations, and financing mechanisms to advance HIE. We analyzed grantee final reports to identify key drivers that helped facilitate and/or accelerate HIE under the State HIE Program as well as key challenges grantees encountered, strategies grantees employed or are considering to overcome those obstacles, and remaining gaps in connectivity.

Study Design

At the conclusion of the State HIE Program in spring 2014, ONC required grantees to submit a close-out report discussing lessons learned, a gaps analysis, and recommendations. Grantee responses were imported into the qualitative research software program NVivo and coded into categories representing the most commonly reported HIE key drivers, challenges, and solutions in the reports.

Principal Findings

Across grantees, the most commonly reported key drivers for successful HIE initiatives were diverse stakeholder engagement to build relationships, establish trust, improve acceptance, align goals, leverage existing HIE assets, and create a sense of ownership for all those involved; strong initial service offerings to drive momentum; clear and consistent policy and regulation; continued marketing of benefits to build awareness and increase adoption; a flexible HIE infrastructure to cope with the evolving nature of health IT; and leveraging payment reform initiatives in order to achieve a critical mass of HIE participants and ensure the utility of HIE services.

The most commonly reported challenges for HIE initiatives were the unexpected resource intensiveness, in terms of time, money, and efforts, for all stakeholders; competing regulations making HIE prioritization difficult; performance limitations of health IT vendors and HIE products; and patient acceptance and lack of common consent policies; and workflow pressures for health care workers adjusting to and incorporating new technology.

Conclusions

The State HIE Program catalyzed progress toward enabling HIE services through a substantial, one-time infusion of funds. However, gaps remain to achieving interoperable intra-state, inter-state, and national HIE exchange. Grantees encountered cross-cutting challenges while implementing HIE activities and reported innovative solutions that can guide and inform similar efforts moving forward and provide an opportunity for grantees to learn from each other’s experiences as they work towards sustainable HIE initiatives.

Implications for Policy, Delivery or Practice

By identifying key drivers, these findings will help policy makers design future programs, service offerings, and policies to advance HIE. Discussing the challenges grantees encountered can help prepare stakeholders for future challenges and set realistic expectations. Grantees can also identify successful strategies used by others to efficiently address their own challenges.
A Baseline Assessment of the Dispensary Workflow in the Birmingham Free Clinic: A Time-Motion Study of Pharmacist Tasks

Arielle M. Fisher¹, Michael Q. Ding¹, Harry Hochheiser, PhD¹,², Gerald P. Douglas, PhD¹
¹Center for Health Informatics for the Underserved, Department of Biomedical Informatics, School of Medicine, ²Intelligent Systems Program, University of Pittsburgh, Pittsburgh, PA

Introduction
Healthcare services in low-resource settings often face distinctive informatics challenges arising from health, economic, and education disparities in underserved populations. The Birmingham Free Clinic (BFC), in Pittsburgh, PA is a free, walk-in clinic offering primary care and pharmaceutical services to a medically vulnerable population. The recent implementation of an electronic medical record (EMR) has produced benefits such as improving continuity of care for patients in the University of Pittsburgh Medical Center (UPMC) network. However, pharmacists report that the EMR deployment has had a negative impact on their workflow efficiency. After a qualitative investigation of these negative impacts uncovered 13 workflow inefficiencies, we conducted a time-motion study to provide an evidence-based understanding of the magnitude of these workflow challenges. The results of this study will guide the development of an information system at the dispensary level grounded in several interconnected informatics interventions. Our results will also serve as baseline data for a similar post-implementation time-motion study which will evaluate the impact of the information system on improving pharmacist efficiency.

Methods
Qualitative observations of pharmacist work at the BFC informed the creation of five task categories and 12 subcategories for our time-motion study. Two researchers used the Time Motion Study application for Android devices to capture different pharmacist activities and their specific durations. Two 3-hour pilot sessions were conducted to compare the agreement between researchers prior to starting data collection. Cohen’s kappa was found to be $\kappa=0.808$ following the pilot sessions. Time-motion data was collected in three sessions between October and November 2013; each session lasted approximately three hours. We conducted a brief interview with the pharmacists to identify tasks from our list of subcategories that they believe add direct value to patient care. Based on this assessment, we calculated the value quotient for each dataset in order to quantify inefficiency in the dispensary workflow. The value quotient is a metric for determining a health system’s success in meeting patient needs while effectively using the resources they have been granted¹.

Results
The five workflow categories and their respective time investments were: patient diagnosis (21.5%), EMR-related functions (14.8%), prescription preparation (39.8%), patient interaction (18.7%), and other (5.2%). Our results showed that the pharmacists invested, on average, the majority of their time into prescription preparation which included five subcategories: traveling (2.4%), hunting for medication (4.8%), dispensing medication (7.3%), labeling medication bottles (21.8%), and duplicate documenting (3.6%). Further, the overall value quotient was found to be 43.5% which demonstrates that over half of the pharmacists’ time is spent completing tasks that they consider to not be directly benefiting patient care.

Conclusions
We believe that this is the first study to quantify how pharmacists spend their time in a low-resource dispensary. Our results show that pharmacists at the BFC spend the majority of their time preparing prescriptions, which is a task they consider to be inefficient. The value quotient demonstrates that there are many non-value-added tasks that we believe could potentially be reduced through the introduction of workflow re-engineering.

This poster describes the conversion of the national Department of Veterans Affairs (VA) healthcare network's corporate data warehouse to a common data model (CDM) suitable for distributed observational research: the Observational Medical Outcomes Partnerships (OMOP) CDM. The CDM allows shared data analysis to have syntactic and semantic interoperability through standardized terminologies such as ICD, RxNorm, SNOMED, CPT, HCPSC, and LOINC. Observational outcomes from electronic medical record systems are becoming more important in comparative effectiveness research, particularly as post marketing surveillance research.\textsuperscript{1} Although randomized clinical trials (RCTs) are the most prominent and strongest research strategy for determining safety and efficacy of new treatments or products, RCTs are expensive, slow, and often do not represent the real world conditions in which the product will be used.\textsuperscript{2} In addition, RCTs may not represent the real world population that will use the treatment or last long enough to identify all the adverse events associated with the treatments.\textsuperscript{2}

The VA has the largest integrated healthcare system in the US with electronic health record coverage from the late 1990s. It is one of the few healthcare systems with extended longitudinal records of covered Veterans and has continuity in patient coverage because eligibility is not related to changes in health insurance seen in other health systems. The VA corporate data warehouse has undergone an initial transformation into OMOP CDM with large-scale data population beginning in 1999 (1998 for drugs). There are approximately 16,927 thousand unique patients in the dataset (see Table 1), with 11,368 thousand of those having at least one encounter (5,559 thousand patients enrolled with no encounters).

Drug cost and procedure cost are pending load. As part of a cooperative effort with the patient-centered Scalable National Network for Effectiveness Research (pSCANNER), we are also transforming the OMOP CDM to the PCORnet data model. VA's OMOP data will be available for initiatives of VA researcher groups and research initiatives of PCORnet. The Observational Health Data Sciences and Informatics (ODHSI) community is developing a suite of data characterization, data quality, cohort generation, comparative effectiveness analysis, and surveillance tools (\texttt{www.ohdsi.org}), and VINCI plans on participating in tool development and supporting use of these tools within the computing infrastructure to support observational cohort analytics. For example, an ODHSI shared quality tool indicates 255,552 records of Sodium Chloride 9mg/ml irrigation solution had a quantity of 1000, e.g. source data used ml vs. bag to record quantity. Strategies to address these types of variations are a future challenge. Financial Support: This study’s work supported with resources and the use of facilities at the TVHS VA and VA SLCHCS and is funded by PCORI contract CDNR-1306-048189 and the VA Informatics and Computing Infrastructure (VINCI) HIR 08-204 and RES 13-457. Prior work described in this paper was supported by AHRQ grant R01HS019913 and NIA grant 1RC4AG039115-01 as part of the American Recovery and Reinvestment Act, National Center for Biomedical Computing (Grant U54 HL108460), and VA HSRR&D CDA-22008-020.

Determining Factors Relevant to Handoff by Role and Patient Population

Karol L. Fleming MBA, JD,1 Ray McKelvy,1 Nathan C. Gonzalez,1 William B. Webb BSPH, MBA,1 Robert L Shapiro MD, MSCI1,2

1 MEDarchon, Inc. 113 29th Avenue South, Nashville, TN 37212
2 Cardiovascular Division, Washington University in St. Louis School of Medicine, 660 S. Euclid Avenue, St. Louis, MO 63110

Background: While electronic handoff tools can be significant,1 a review of the literature has found significant variability in the factors that should be included. Many e-handoff tools provide a one-size fits all solution and do not consider the specific information needs of users based on their role or patient population. Methods: Doctors and nurses with at least two years of clinical experience were selectively recruited based upon their role, specialty and patient population. After informed consent, subjects were asked to narrate a clinical handoff. They then were presented with a number of factors identified from the clinical literature as potentially important to handoff and asked to classify these factors as things that should always, sometimes or never be included. Subjects were also asked to describe the circumstances that would lead to including factors listed as “sometimes” and to list any factors not included. These responses were codified and summarized using descriptive statistics and the Z score. The kappa coefficient was used to demonstrate the agreement between whether a participant included a factor in their vignette and how they subsequently categorized that factor (always include vs. never include) in the prompted exercise. Classification and Regression Tree modeling (© Salford Systems) was used to determine whether a factor should be presented based on user attributes, patient attributes, and other variables gleaned from the narrative surrounding when to include variables classified as “sometimes.” Results: 23 of 24 recruited subjects completed the study. Figure 1 shows the percentage of participants who included each factor in their handoff vignette, while Figure 2 demonstrates the extent to which subjects indicated they would include factors. The average kappa for intra-observer reliability was 0.21. Participants from the surgical setting showed poorer concordance between vignette and classification (κ=0.12) than those from the ICU (κ=0.21) or medical settings (κ=0.26). In subgroup analysis, practitioners in the ICU were more likely to include urine output (p=0.06) and less likely to included patient condition (p=0.05); medical physicians were more likely to include a patient picture (p=0.06) and less likely to include the unit admit date (p=0.07) or surgical procedures performed (p=0.03); physicians were more likely to include patient condition (p=0.10) and less likely to include precautions (p=0.01), pain medication information (p=0.04) and urine output (p=0.05); and clinicians seeing pediatric patients were less likely to include patient condition (p=0.03) and room number (p=0.10). Factors suggested by subjects but not found in the literature included information related to: the patient’s family, current care team, catheters, lines and drips, maternal/gestational history, recent events, and discharge planning. Subjects indicated more often than not that those factors categorized as “sometimes” were only discussed when abnormal. Models were successfully produced for each handoff factor found in the literature. Conclusion: This study suggests several new factors that are important for inclusion in an electronic handoff tool as well as the complexity of building such a tool. In order to optimize the user experience and use related hazards, an e-handoff tool must contemplate the user’s role, specialty, patient population and the abnormality of data when deciding whether to display a certain factor.

Figure 2: Factors in Guided Analysis

Bridging the MedlinePlus Cloud to askMEDLINE

Paul Fontelo, MD, MPH, Fang Liu, MS
National Library of Medicine, Bethesda, MD

Abstract
We developed a Web interface to show the top searched terms from MedlinePlus Cloud and direct the top searched terms to askMEDLINE’s query database. The bridge from MedlinePlus, a patient and family health information resource to askMEDLINE provides recent evidence from PubMed for patients and health care professionals.

Introduction
MedlinePlus is online health resource for patient and families. The MedlinePlus Cloud provides the list of top 100 searched terms from patients1. It is updated daily. The results are displayed with text cloud, a visualization tool to quickly learn the most searched terms in the list. askMEDLINE was designed to search PubMed using free-text queries without knowing complex search strategies2. askMEDLINE has an additional feature that displays the previous user queries. We wanted to build a channel between MedlinePlus top searched terms to the askMEDLINE database.

Methods
The source code from the MedlinePlus Cloud Web page was parsed using a script and then the top 100 terms and their respective rankings were retrieved from the source code. A Web interface was generated to dynamically display by alphabetical order or ranking using text cloud visualization (top ranked terms in the larger font format)3. Users can choose to view the terms either by rank order or in the alphabet. A link was embedded with each term to redirect to previously searched questions in askMEDLINE database and references to the PubMed citations.

Result
An example of the top 100 MedlinePlus terms is listed with text cloud visualization (Fig 1). The link for each term directs users to the previous queries in askMEDLINE database (Fig 2). Preliminary feedback was positive. The responses mentioned that the concept of a bridge Web interface between MedlinePlus and askMEDLINE queries database would benefit both patients and physicians.

Conclusion
A MedlinePlus to askMEDLINE bridge with text cloud visualization adds another resource that may benefit both physicians and patients to find more information on related medical conditions that they might not have considered.

Implementation of a Clinical Decision Support Tool to Improve Guideline Compliance in the Prevention of Early-Onset Group B Streptococcus Infections in Neonates

Louise K. Francois Watkins, MD, MPH,1,2 David A. McLean, MD,3 Marion B. Nihen, RN,3 Jonathan M. Wortham, MD,2 Melvin Crum, MS,2 Philipp Carner,2 Mike Jordan,4 Stephanie Schrag, DPhil

1Epidemic Intelligence Service Program, Atlanta, GA; 2Centers for Disease Control and Prevention, Atlanta, GA; 3Lehigh Valley Health Network, Allentown, PA; 4GE Healthcare, Barrington, IL

Early-onset Group B streptococcus (GBS) disease is the most common infectious cause of morbidity and mortality during the first week of life. Approximately 25% of women are asymptomatically colonized with GBS in the genital tract; early-onset GBS disease occurs in newborns when the bacteria are passed from mother to newborn during delivery. Evidence-based guidelines for prevention of early-onset GBS were developed in the 1990s and include recommendations for universal screening of mothers for GBS colonization and administration of intrapartum antibiotic prophylaxis to colonized mothers and those with specific risk factors.1 As a result of widespread guideline implementation, the incidence of early-onset GBS has decreased by more than 80%. Despite this success, errors in guideline implementation have recently been found to occur in more than half of cases of early-onset GBS disease,2 suggesting improved guideline adherence may prevent additional cases of disease. Routine use of a clinical decision support (CDS) tool at the time of patient admission may streamline and optimize guideline implementation.

The Centers for Disease Control and Prevention (CDC) developed an algorithm that uses 13 independent patient variables derived from the guidelines to generate patient-specific, evidence-based recommendations for intrapartum antibiotic prophylaxis for prevention of GBS disease. CDC partnered with Lehigh Valley Health Network (LVHN) in Allentown, PA, an academic medical center performing approximately 4,000 deliveries per year, to create a CDS tool embedded into the Centricity Perinatal electronic medical record (EMR) used at LVHN. Five variables are imported to the CDS tool automatically via existing data fields in the EMR, and a response to one variable, intrapartum screen result, is hardcoded as “unknown” because this testing option is unavailable at LVHN; the remaining 7 variables require entry by the clinician. Values for these variables are then submitted to CDC where they are leveraged by a rule engine (32 rules, modifiable by developers but not end-users) and processed by the algorithm, and a response is generated providing the user with an evidence-based patient management recommendation at the point of care.

The CDS tool was released for use by clinicians at LVHN in August 2014. Users are electronically prompted to employ the CDS tool at the time that electronic admission orders are placed for each patient admitted to the labor and delivery unit. In the first four months after introduction of the tool, there were 1460 total deliveries at LVHN, and the CDS tool was used in 638 cases (44%). Feedback from clinicians was solicited and used to adjust the interface and to tailor response messages to improve their clarity.

The impact of the CDS tool on guideline compliance at LVHN will be assessed after one year of use, with particular attention to areas where compliance may be weaker, such as preterm delivery when GBS screening result is unknown, and antibiotic choice in the setting of penicillin allergy. This project serves as an example of the successful integration of a CDS tool into an existing EMR in order to minimize the time and effort required for clinicians to verify guideline-based recommendations for patient care, and holds important implications for other conditions with complex management guidelines.

A Gap Analysis of Competencies and Curriculum in Host-Site Projects of a Field-Based Informatics Fellowship

Laura H. Franzke, PhD, MPH; Sridhar Papagari, MS; Regina Bess, MPA; Herman Tolentino, MD; Brenna Baccaro, MPH; Centers for Disease Control and Prevention (CDC), Atlanta, GA, USA

Abstract
A program overview of an Applied Public Health Informatics Fellowship program that provides a 1-year training at state, tribal, local and territorial health departments. A gap analysis is performed to map and analyze the curriculum and competencies to the host assignment projects. The results will guide how to improve the curriculum and competencies to better serve the informatics needs for health departments.

Background
During 2011, the Centers for Disease Control and Prevention, in partnership with multiple national public health organizations, developed a 1-year Applied Public Health Informatics Fellowship (APHIF) program. APHIF provides informatics graduates the opportunity to participate in an applied training program in public health informatics (PHI) at state, tribal, local, and territorial (STLT) health departments. The fellowship was developed to respond to an informatics workforce shortage among STLT health departments, and to also provide new PHI graduates an opportunity to apply informatics knowledge and skills on host-site informatics projects.

APHIF offers an applied, competency-based curriculum that includes service-learning opportunities; each year APHIF accepts up to ten fellows that are placed at STLT health departments. The PHI competency domains that guide service-learning activities include: (1) analysis, assessment, and evaluation; (2) communication; (3) cultural competence; (4) community dimensions of practice; (5) public health sciences; and (6) leadership and systems thinking. Each fellow is matched to a mentor who provides a learning opportunity to participate in or lead a PHI project. Additional fellow learning opportunities include: orientation, monthly seminars, communities of practice (COP), and peer-to-peer learning on various public health informatics topics. The host projects are different in scope and skill requirements, allowing fellows to be matched to their area of expertise and learning needs. Examples of host site assignments topics are as follows: electronic lab reporting, meaningful use, interoperability and/or electronic health records. Since 2012, (n=27) fellows have been placed in 15 states.

Methods
A two-fold gap analysis will be performed for the APHIF program to compare between actual and desired performance. First, the APHIF curriculum will be mapped to the PHI competencies, and second, the host site projects will be mapped to PHI competencies. The mapping and analysis will examine current to desired fellowship performance state; this will elicit potential gaps and strengths in the curriculum, competencies, and host projects. This gap analysis will guide how the curriculum and competencies can be improved to more fully support the STLT health department’s informatics needs. Additionally, this gap analysis will guide mentors and supervisors about how to potentially improve host assignment projects to provide additional learning opportunities.
Abstract:

The current means for reporting the door to healthcare provider time of patients is neither accurate nor reliable. We have created a reliable method of automatically capturing this time using Bluetooth-based technology that does not hinder the Emergency Department (ED) workflow. The results show accurate measures, within seconds, of patient wait times and reliable detection of providers within key locations, without negatively impacting the ED workflow.

Introduction:

The Center for Medicare and Medicaid Services (CMS) requires that EDs log and report certain performance measurements including the door to healthcare provider time for the patients. Current data collection methods for time performance measures that EDs employ are not automatic in nature and require extra work for the provider to document the time a patient is seen. Our work seeks to provide an automatic method of provider time documentation, while not interfering negatively with the ED workflow.

Methodology:

Using the wireless sensor technology, single board computers with Bluetooth detection and automatic time correction software were installed on the ceilings above the hospital beds in the center of ED rooms. These computers detect when a Bluetooth beacon (a broadcaster) is within the measuring range and calculate the distance between itself and the beacon. This distance is used along with the accepted room radius to determine when a healthcare provider (carrying the beacon) is in an ED room seeing a patient. If the healthcare provider is indeed in the room, then the clinician time for the door to clinician time is logged. The door to clinician time is calculated from subtracting the door time, which was collected at the time of patient data registration, from the clinician time. Clinicians’ measure of handwritten times were compared against our detected beacon times.

Results and Discussion:

A total of 17 out of the 500+ clinician–patient encounters (to this date) have been reviewed, of which six set of data were excluded because the care was provided by resident trainees, who were not given the beacons. The overall results show that the recorded door to clinician times were accurate where the beacons were detected and the times recorded in seconds. The times recorded by the software were compared with time.gov for accuracy and also compared against the clinicians’ handwritten times, but the logged times are more accurate.

Conclusions and Future Research:

As our preliminary results show in the ED, this inexpensive Bluetooth broadcasting technology offers an automatic and reliable way to track provider-patient encounters accurately to the second. We hope to extend the study to include assessment of team interactions, given the installation of additional sensors in areas such as over the hallway patient beds and the Triage area.

An Examination of Standalone Personal Health Record Use by Patients with Type 2 Diabetes

Kevin T. Fuji, PharmD, MA1,2, Amy A. Abbott, PhD, RN1,3, Kimberly A. Galt, PharmD, PhD1,2

1Creighton University Center for Health Services Research and Patient Safety, Omaha, NE; 2Creighton University School of Pharmacy and Health Professions, Omaha, NE; 3Creighton University College of Nursing, Omaha, NE

Introduction
The use of personal health records (PHRs) by patients has been hypothesized to improve patient knowledge about their medical conditions, aid in maintaining comprehensive health records, and facilitate patient engagement in their own care.1 PHRs hold particular promise for patients with chronic conditions, such as diabetes, who often manage multiple medications and co-morbidities.1 However, there is limited information on the actual impact of this technology on clinical outcomes and self-care behaviors. The purpose of this study was to examine the impact of standalone PHR use on hemoglobin A1c (HbA1c) and social cognitive outcomes of patients with type 2 diabetes.

Methods
This pilot study utilized a randomized controlled trial in which 140 participants were assigned either to a PHR group who used Microsoft HealthVault to manage their diabetes-related health information, or to a usual care control group. Outcomes were assessed at baseline and 3-6 months later. HbA1c levels were obtained from medical records, while social cognitive outcomes were measured via a patient survey: 1) modifying factors to disease self-management (perceived barriers to self-management; diabetes education; and social support); 2) diabetes knowledge; and 3) self-efficacy. A score of 1-5 was calculated for each concept, with higher scores indicating a more positive response. Interviews were also conducted at 3-6 months with all PHR group participants, and analyzed using an iterative thematic analysis.

Results
A total of 117 participants completed the study (61 control, 56 PHR). No significant change in HbA1c was observed in either group (Control: 7.53%±1.53% to 7.75%±1.22%, p=.252; PHR: 7.86%±1.96% to 7.98%±2.01%, p=.535). No significant changes were observed in the control group for social cognitive outcomes: modifying factors (3.78 to 3.70, p=.204); self-efficacy (3.77 to 3.80, p=.317); and diabetes knowledge (4.13 to 4.19, p=.254). In the PHR group, no significant changes were observed in modifying factors (3.78 to 3.83, p=.297) or self-efficacy (3.82 to 3.83, p=.657); however, there was a significant improvement in diabetes knowledge (4.11 to 4.25, p=.029). Five themes emerged from the thematic analysis: 1) few people use the PHR more than once or twice; 2) PHR users find value in self-management of their health; 3) PHR users are persons who are already tracking information; 4) PHR users do not proactively share the information with their providers; and 5) providers who knew patients were trained in PHR use did not ask for the information.

Conclusion
Short-term use of a standalone PHR improved patients’ diabetes knowledge, but failed to have a significant effect on HbA1c and other social cognitive outcomes. While the PHR has value for self-management, PHR users were already using existing tools and did not engage in sustained PHR use. In order for PHRs to help patients move from enhanced diabetes knowledge to improved clinical and self-management outcomes, it must demonstrate clear value beyond existing health information tracking tools and promote information sharing between patients and providers. Future PHR design could incorporate patient-centered decision support tools (e.g. preventive care reminders or identification of potential drug interactions) that provide value beyond use as an information repository. Providers should also consider introducing the PHR as a self-management tool for patients during diabetes education.

Therapeutic Area and Research Use Case Based Data Profiling & Quality Assessment Framework

Purav Gandhi, MBBS, MBA\(^1\), Jasmine Avasia, BSc\(^1\), Shrestha Anantha, BE\(^1\), Rajinder Sobti, BTech, MBA\(^1\)

\(^1\)ConvergeHEALTH by Deloitte, Newton, MA

Abstract

We have developed a framework for data profiling and quality assessment for real-world evidence that performs an overall data quality assessment, therapeutic area, and research objective based evaluation. The profiler leverages definitions and rules from a content library which can be updated as understanding of data quality evolves, and the findings presented in a highly intuitive user interface to simplify data due diligence and quality assessment process.

Introduction

Data quality is important in real-world evidence based research using clinical and claims data, to determine the feasibility and level of confidence in the results of a study. As our understanding of secondary uses to data improves, we recognize that data quality is not only measured in quantitative terms such as number of patients and longitudinality of the data set, but now has a lot of qualitative considerations such as comprehensiveness across diagnosis, treatment, procedures, and similar areas. Also, clinical nuances vary across disease areas, such as specific biomarkers to be tracked for research. Currently limited number of such intelligent data profiling solutions exist that can profile and evaluate data quality based on therapeutic area of interest.

Method

We have designed a unique data profiling and quality assessment framework (Data Asset Explorer) that helps assessment of data quality at three different tiers: (1) General data profiling and quality assessment, which includes validation of data against metadata like number of rows, longitudinality, overlapping of fields across diagnosis, treatment, procedures, etc., (2) Therapeutic area based profiling and assessment, that includes validations such as data availability for tests and biomarkers related to the therapeutic area, number of follow-ups for specific tests, and disease specific longitudinality threshold, and (3) Research objective specific profiling, which evaluates the presence of specific data fields relevant for the research objective (e.g., presence of cost data for economic impact analysis), and the data density in those fields.

Solution

Data Asset Explorer profiles the data across different data sources through a generic and extensible metadata framework, Common Meta Data Model (CMDM). It is extensible to support different types of healthcare data source as indicated in the diagram. Query Generator leverages the data quality rules and profiles from Content Library (central repository of the rules, measures and models) and CMDM to query the specific data sources and also compare different data sets. The results of the profiling and quality checks are rendered through a visual interface.

Discussion

Data Asset Explorer will help the researchers navigate through the snapshot (both generic and targeted) of different sources for evaluation and comparison purposes before. This will generate efficiency in data due diligence and feasibility assessment process for various studies. We are in the process of testing the framework for extensibility to other data sources such Omics data, as well as its ability to capture comprehensive rule set for every disease area.
Dashboard Visualizations of Emergency Department Throughput Metrics

Swaroop Gantela, MD, Todd R. Johnson, PhD, Nnaemeka G. Okafor, MD, MS, David J. Robinson, MD, Amit M. Mehta, MD, Charles L. Maddow, MD, Brent R. King, MD, Tina E. Chacko, PA, Salsawit Shifarraw, BBA, Vickie Nguyen, MS, Adriana Stanley, BS, Amy Franklin, PhD

1 University of Texas Health Science Center Houston, Houston TX; 2 Nemours/Alfred I. duPont Hospital for Children, Wilmington DE; 3 Memorial Hermann Healthcare System, Houston TX

Introduction

The Centers for Medicare and Medicaid Services are exploring the use of payment determination measures that will include Emergency Department (ED) throughput metrics. As timely and effective care becomes defined by (non)adherence to goals for care processes, such as overall length of stay and time from admission decision to departure, providers and administrators need a way to improve efficiency. We discuss the use of visualizations of throughput data to provide cognitive support for real-time comprehension and projection of the state of ED care processes. Borrowing from Pimentel and Barrueto’s application of statistical process control (SPC) methods in understanding historical ED processes, we propose that SPC visualizations of real-time data can provide visual statistical cues that may more accurately capture true process performance and potentially provide early warnings of process change.

Methods

SPC visualizations support recognition of the normal variation inherent to a process and “special cause” variation resulting from possible statistically significant changes in process behavior. For example, in Figure 1, the SPC chart indicates a care process exhibiting normal variation until the latter points where a specific trend criterion is met (10 points out of 12 above the median), suggesting a special cause or process change. Even though many points prior to this are above the target, those points are not statistically different from the median. In contrast, the goal-based chart in Figure 2 highlights all over-target values, which encourages treating all variation as special cause—an approach shown to increase process variation.

Example Metric: Time from Provider Assigned to Disposition Selected

<table>
<thead>
<tr>
<th>Goal: less than 120 minutes</th>
</tr>
</thead>
</table>

**Figure 1.** Statistical Process Control chart  
**Figure 2.** Goal-based visualizations

Conclusion

SPC methods have been long used in mechanical production environments to assess historical process performance and detect real-time deviations from control. While the ED environment is less deterministic, highlighted visualizations of control charts can play a supportive role in ED situation awareness and decision-making.

Electronically Collecting Nocturnal Heart Failure Information

Cubby L. Gardner, MS, RN, FNP-C1, Harry B. Burke, MD, PhD2
1Daniel K. Inouye Graduate School of Nursing, 2School of Medicine
Uniformed Services University of the Health Sciences, Bethesda, MD

Background

The current approach to the outpatient management of heart failure combines patients’ retrospective self-reports of symptoms and activity with a physical examination and laboratory results during a routine office visit. Clinicians expect that patients will accurately recall significant changes in symptoms and activity since the last clinic visit. Unfortunately, there is a great deal of variability in patient’s self-reports and in subjective assessment instruments, recall is, many times, not veridical with past events and it may be especially difficult for heart failure patients because of the prevalence of mild cognitive impairment due to both heart failure itself and advancing age. Thus, retrospective objective and subjective information recalled at clinic visits may not provide the accurate, complete, and detailed information that clinicians require for the optimal management of their patients. We provided patients with physiologic devices to measure their clinical status at home. We hypothesized that patients would be able to use these devices overnight in their homes and that this would improve the information available to clinicians.

Methods

Patients were trained on five objective and subjective data acquisition devices (weight scale, blood pressure monitor, pulse oximeter, actigraph, and an iPad-based subjective question set). They used them to collect data at home, overnight for up to six nights. The raw data was downloaded using device-specific software, cleaned using R statistical language, and uploaded into the MySQL study database. We expected patients to use the scale once a night, BP and iPad twice a night, and the continuous devices all night for 8 hours. The ratio of observed over expected (O/E) device use, where 1.0 is observed = expected, was calculated and tested using the Student’s t-test.

Results

Participants were 39 clinical heart failure patients, mean age 68.1 (SD, 12.3), 71.8% male, New York Heart Association functional class I, 10 patients; class II, 22 patients; and class III, 7 patients. Three of the devices were used as expected (Table). The scale was used significantly less than expected O/E 0.80, p<0.001. The pulse oximeter, worn on the wrist overnight to collect heart rate and blood oxygen saturation, was worn as expected O/E 0.90, and was marginally significant, p=0.05. The actigraph, which was worn on the wrist and measured activity, was used significantly more than expected, O/E 1.93, p<0.001.

^1Ratio of observed over expected (O/E) device use where 1.0 is observed equals expected.
^2The results are based on the 24 patients who used the scale.
^3Three patients used a Zephyr device for activity; they are not included in the activity results.

Discussion

We found that the labor-intensive scale, which had to be set-up for each measurement, was used less than expected, whereas the actigraph, which is simply placed on the wrist, was used more than expected. In another study we assessed patient perceptions of device usability and found high acceptance. This study is important because we need to know which devices patients will actually use in their home and why they will use them.

The views expressed are those of the authors and do not reflect the official policy or position of the Uniformed Services University of the Health Sciences, the Department of the Defense, or the United States government. All devices met Protected Health Information (PHI) and Personal Identifiably Information (PII) requirements. WRNMMC IRB Protocol number 400924-4.
Evaluating the Effect of a Nursing Flowsheet Merge on Clinical Nursing Documentation Efficiency in a Research Hospital

Kyungsook Gartrell, RN, PhD1, 2, Helen S. Mayberry, MSN, RN2, Michael Krumlauf, RN, BSN2, Michael Nansel, RN, BSN3, Minnie Raju, MS, RN3, Gwenyth R. Wallen, RN, PhD2, Caitlin W. Brennan, PhD, APRN2

1National Institutes of Health/National Library of Medicine, Bethesda, Maryland; 2National Institutes of Health/Clinical Center Nursing Department, Research & Practice Development Section, Bethesda, Maryland; 3National Institutes of Health Clinical Center, Department of Clinical Research Informatics, Bethesda, Maryland

Introduction

The National Institutes of Health (NIH) Clinical Center has used the clinical research information system (CRIS) to support the documentation of clinical care and biomedical research since 2004. CRIS is an amalgamation of vendor-based applications that encompass the NIH electronic health record (EHR). The core system in CRIS is the Sunrise 14.3 application suite. CRIS is used by physicians, nurses, and ancillary and administrative staff in performing a variety of information tasks related to patient care. Tasks include 1) managing registration, admissions, and discharges and transfers, 2) maintaining demographic data and clinical research protocol information, 3) providing bed management, 4) attributing medical activities (orders, appointments and documents) to specific research protocols, 5) retrieving laboratory and radiology results, 6) documenting care plans, vital signs, medication administration, intake and output, and progress notes, and 7) reviewing outside documentation. Approximately 90% of the NIH Clinical Center’s medical record content is generated from CRIS. The nursing outcomes management team and the department of clinical research informatics routinely collaborate, with a goal of using CRIS data to inform quality improvement and patient safety efforts.

One problem with nursing documentation in the CRIS was that nursing assessment and intervention data were documented in separate screens, making information difficult to find and to document. Little is known about best practices for use of nursing data in EHRs to communicate plans of care among multiple professions. The significance of this evaluation is that it serves as the necessary first step in describing the contributions nurses at NIH make in translational research and how other members of the interprofessional team use nursing information in patient care. In December of 2014, the content from two nursing flowsheets was merged into one flowsheet to better reflect the continuity of care provided by nurses. The aim of this investigation is to evaluate the effect of the nursing flowsheet merge on clinical nursing documentation efficiency.

Methodology

A retrospective query from CRIS will be used to extract data for six months pre- (June-November 2014) and six months post- (January-June 2015) implementation of the nursing flowsheet merge. The effect of the nursing flowsheet merge will be measured by change of frequency of usage between pre- and post-data in several categories. Nursing assessment and intervention information is documented in 21 sections in CRIS that can be classified into 5 categories (physical, psychosocial, patient education, activity, and safety). Nursing documentation will be quantified as the total number of saved and modified notes in each category. Frequency of usage will be calculated by total number of times specific categories of CRIS were accessed to view and read information.

Evaluation Results and Conclusions

SPSS will be used for statistical analyses. Descriptive statistics will include frequencies and percentages to describe the total number of nursing notes saved and modified and the total number of times nursing assessment and intervention notes were accessed for viewing purposes. Chi-square tests will be used to investigate whether distributions of nursing assessment and interventions differ between pre- and post-implementation. Each of the aforementioned 5 categories of nursing documentation will be presented for the pre-and post-implementation comparison. If a statistically significant difference is detected between inpatient and outpatient units, the data will be reported separately. Expected results are that increased efficiency of nursing documentation occurred as a result of the flow sheet merge and is quantified as an increase in the number of saved and modified nursing notes, and by an increased number of viewed nursing notes.
Development and Validation of a Measure for EHR Related Unintended Consequences with Direct Care Registered Nurses

Sheila M. Gephart, PhD, RN; 1 Judy Dye, MS, NP; 1 Alycia Bristol, MS, CNS, RN; 1 Brooke A. Finley; 1 Jane Carrington, PhD, RN 1
1 The University of Arizona, Tucson, AZ

Introduction
Electronic Health Records (EHRs) are being widely implemented with promise to support information availability, coordination of care and clinical decision making. Yet, the swift implementation of these imperfect systems may threaten patient safety as clinicians, including nurses, devise EHR workarounds. Guided by previous qualitative studies, a quantitative measure (i.e. CG-UCE-Q) was developed to measure the impacts and prevalence of unintended EHR consequences. The purpose of this study was to determine the extent to which the measure is valid and reliable then use it to describe nurses’ frequency of experience with EHR related unintended consequences.

Methods
Nurse Informaticist (NI) experts were recruited and electronically completed a survey identifying each item’s relevance on the CG-UCE-Q. Data was analyzed using descriptive statistics and items were grouped based on: 1) relevant or relevant with minor revision; and 2) unable to assess relevance without revision or irrelevant. Reviewers suggested improvements and 2 items were added for round 2. Direct care R.N.s were then recruited from a single health system with 2 separate hospitals to complete the CG-UCE-Q. The same survey was distributed 2 weeks later and responses to the two testing times were linked. Psychometric testing of reliability and validity was then conducted. Qualitative data was also collected and is reported elsewhere. The measure is scored by assessing the frequency with which an UC occurs on a scale from 0-6 (0= never, 1= once a year, 2=once every couple of months, 3= once a month, 4= once a week, 5= once a shift and 6= multiple times a shift).

Results
NI experts (N=5) ranged from moderately to extensively expert. After two rounds of testing, the content validity index was 0.96 and 44 items were included (2 added based on experts’ recommendations). Then, of 1100 RNs invited to participate, 226 responded and were screened for eligibility, 113 eligible RNs completed the first survey. While 87 completed the second survey, after removing incomplete responses, 68 were usable for test-retest measurement. R.N.’s worked in various acute care settings, although predominantly represented medical-surgical (26%) and intensive care (32%). Ages varied widely, 91% were female, and 74% were B.S.N. prepared or greater. The CG-UCE-Q was highly internally consistent (Cronbach’s α = 0.94; ICC=0.91) with strong item-total correlations (0.30-.80) for the majority of items. Individual responses changed over time ($X^2 = 980 (39), p < 0.001$) and did not support test-retest reliability, although median scores across the groups were highly similar over time. Highest item-total correlations were identified for threats to patient safety when attempting to assess risk for complications (0.79), when coordinating care at discharge (0.79), transferring patients within the hospital (0.75), and when coordinating care within the hospital (0.75). Highest frequency of UCs (i.e. at least once a shift to multiple times a shift) were identified for increased workload (M=4.9, SD=1.5), interruptions requiring task shifts away from the computer (M=5.55, SD=0.77), changing workflow (M=4.4, SD=1.8), and duplicative documentation (M=4.9, SD=1.8).

Discussion
This is the first, to our knowledge, quantitative measure of nurse experience with EHR related UCs. Nurses experience UCs frequently and indicate they threaten patient safety in care at least once a shift to once a week. The highest risk relates to poor information availability or EHR misrepresentations that occur during transitions and when care coordination and medication administration is an issue.

Conclusion
Psychometric testing supports the internal consistency and content validity of the CG-UCE-Q. Test-retest reliability demonstrated that the measure is not stable, but may reflect a changing nurse experience over time. Construct validity testing is underway. Of most concern, nurses reported high frequency of UCs related to patient safety, particularly at times when coordination and transitions in care occur.

\textsuperscript{3}Harvard Medical School, Boston, MA

Introduction

Electronic Health Records (EHRs) that are highly customizable to increase end-user satisfaction are considered desirable by most health care systems [1]. Customization of EHRs offers an opportunity to optimize the system to meet a variety of clinical, administrative, and policy needs across an institution or enterprise. However, configuring the system without a set of principles and best practices to guide accurate and consistent data capture is a significant challenge for any organization.

Standardizing clinical data definitions in an EHR increases overall data consistency [2]. Defining how clinical data is structured within an EHR is constrained to the actual functionality of the system. The aim of this project is to (a) describe the principles and best practices for structured data capture in documentation forms, and (b) to conduct a preliminary evaluation of a sample of documentation forms to assess how well they meet the defined principles and best practices.

Methods

A workgroup was formed and began with an iterative process, including basing decisions on data standards such as HL7 and other prominent informatics principles.

After defining the preliminary principles and best practices, it was determined that a baseline assessment needed to be completed for a sample of existing forms. From a recent set of submissions to the workgroup for locally managed structured data elements, a sample of 44 structured documentation forms consisting of a total of 310 structured data elements was chosen to complete this task.

During the review, each form was analyzed using the pre-defined principles and best practices. Principles and best practices that were considered “Not Applicable” to the documentation forms being assessed were omitted from the analysis.

Results

The effort of the workgroup resulted in a preliminary set of 7 principles for building structured data elements. It was determined that one or more best practices could be related to each principle. For example, the principle “Promote reuse and sharing of data elements” can be related to the best practice of “If a structured data element has the same function on multiple forms (e.g. documentation of pain level), then it is best to try to reuse the same structured data element on all the structured documentation forms.”

When the baseline assessment was completed, the “avoiding repeating details” and “using singular naming” instead of plural was met 100% of the time. The principles of “using a structured data element”, “use an additional smart data element with specific details”, and “removing “other” from category lists” were met 0% of the time.

Discussion

The definitions of principles and best practices for structured clinical documentation should be clear and concise. After completing the baseline assessment, the effort to obtain consistent data capture within the structure data documentation forms is a complex problem in which solutions will need to evolve over time. The results are extreme due the preference to build the structured data forms by user preference over quality data is an issue that cannot be immediately fixed. Also building to the specifications of the end-user for a convenient UI is considered a significant aspect of the problem. In the short term, this line of work will continue to evolve including recommending specific data requirements for consistent data capture and sharing data elements to improve data consistency and quality over time.

Streamlining Access to Cancer Data - An Institutional Experience

Leanne Goldstein, DrPH, Rebecca Ottesen, MS, Kelli Olsen, MS, CTR, Janet Nikowitz, CTR, Joyce Niland PhD; City of Hope, Duarte, CA

In this Big Data-era, the lack of large standardized databases of clinical data on all cancer patients represents a void that can be considered “criminal”. City of Hope (COH) has embarked on the creation of such a Disease Registry of standardized clinical data for any cancer site, to support genotype-phenotype analyses, tissue correlations, outcomes, and quality of care research. Our approach to protocols, privacy, security information modeling, and data integration will be described.

When even the tiniest companies can track every piece of data, predict their trends, analyze cohorts and monitor their progress, why can’t we create such a database for cancer patients, to allow us to learn from patients’ experiences and make more educated treatment decisions to extend and improve lives? In a time where access to data is crucial for making decisions about clinical care, COH is streamlining the process of obtaining data used for research and informing treatment decisions through the creation of an institutional Disease Registry. Such a registry is critical to make new discoveries towards precision medicine, conduct genotype-phenotype research, tissue correlative analyses, outcomes research, and quality of care assessments. In many institutions, it can be difficult to obtain research study approval by the Institutional Review Board (IRB) because the submitted protocol may come back with concerns regarding data security or other issues that often delay research. An additional layer of complexity is that data for outcome and tissue correlative studies are typically difficult to obtain because the information is often collected in various data silos across the institution. Principle Investigators (PIs) tend to utilize their fellows and residents to collect the data elements required for their research. This information is typically entered on to unreliable and unsecured spreadsheets, and at the end of the study the valuable information abstracted is often never used again. All of this is disadvantageous to patients who are in dire need of obtaining modern life-saving treatments based on current research and data.

The COH Disease Registry program falls under an IRB-approved “umbrella” protocol which dictates the infrastructure for collection of data for all cancer disease sites, describing the data collection scope, security, privacy, honest broker, and data integration processes. Each disease site will be supported by a linked “spoke” protocol, as defined by disease-specific research teams, to allow the collection and access to pooled institutional data, including information collected as codified elements in the Electronic Medical Record (EMR) as well as data abstracted by the Cancer Registry. We aim to use common data model CDM version 5 in OMOP format. Existing data such as data from pathology synoptic reports are integrated into the Disease Registry to allow physicians to have codified data from the time of diagnosis. Natural language processing is being used to facilitate the abstraction of data elements by Disease Registry Systems Analysts of information found in unstructured text. When additional data for a research study are required, it can be abstracted from dictations in the EMR such as clinical notes or MRI scans. Detailed data beyond the elements in the EMR and Cancer Registry are entered into a secure REDCap database. All Disease Registry data across cancer sites will be integrated via the Enterprise Data Warehouse. It will also be incorporated into a data mart for our internal i2b2 instance so that users across the institution will have enhanced capabilities for refining their queries and targeting the specific cohort or specimens they wish to use in research. A library of oncology based queries will be developed that could be used across institutions.

The Disease Registry program will focus on collecting a variety of oncology based data elements and optimizing tools for data abstraction. We aim to coordinate the effort by PIs interested in specific diseases, approval through the IRB, enhancements to the security of data collection, and retention of study specific data for future uses thereby reducing duplicative and redundant efforts and wastes of research money and resources. Ultimately the Disease Registry program will allow us to maintain an open and collective institutional data repository that will generate knowledge and research in order to improve the lives of cancer patients treated at the COH. Furthermore, the Disease Registry will serve as the vehicle to capture and export the clinical / phenotypic data required for our new membership in the national Oncology Research Information Exchange Network (ORIEN).

A Tale of Two Layouts: Vignette versus Structured Interview for Layout of an Electronic Handoff Tool

Nathan C. Gonzalez,1 Ray McKelvy,1 Karol L. Fleming MBA, JD,1 William B. Webb BSPH, MBA,1 Robert L Shapiro MD, MSCI1,2

1 MEDarchon, Inc. 113 29th Avenue South, Nashville, TN 37212
2 Cardiovascular Division, Washington University in St. Louis School of Medicine, 660 S. Euclid Avenue, St. Louis, MO 63110

Background: The benefits of an electronic handoff tool on patient care are known to be significant. However, our review of the clinical literature has found no studies focusing on the usability of such a tool. Poor usability may limit adoption and gains of an e-handoff tool and the present study sought to define the proper layout (user experience) to support current practice.

Methods: Doctors and nurses with at least two years of clinical experience were selectively recruited based upon their role, specialty and patient population. After giving informed consent and completing a pre-study survey about their practice and handoff tendencies, subjects were asked to narrate a clinical handoff without disclosing PHI. They then were presented with a number of visualizations for handoff data and asked to arrange the factors on an imaginary computer screen. These responses were codified and summarized using descriptive statistics and the Z score.

Results: 24 subjects participated in the study; however, 1 participant was paged and had to drop out. 23 subjects completed the study and produced data that could be analyzed. Figure 1 shows the relative position of the various factors in the narrated handoff with 95% confidence intervals. The majority of participants created a screen layout with either two (43%) or three (39%) columns. In subanalysis, those internal medicine and medical subspecialty physicians were more likely to prefer a three column format (0.7 vs. 0.2; p=0.012). No other subgroups showed a significant difference in preference although nurses trended toward preferring a less complex column displays (0.86 vs. 0.50; p=0.107). Figure 2 shows the relative position of the various factors when arranged by the participants. While no measures reached significance in subanalysis, precautions tended to be placed closer to the end by surgeons (p=0.13) and those clinicians caring for pediatric populations (p=0.16); patient status was placed closer to the end by physicians (p=0.26); and a summary of clinical events was placed closer to the end for ICU-based clinicians (p=0.21). Conclusion: Our study demonstrates that the user experience for a handoff tool should be customized based on the user’s role (MD vs. RN), specialty/area of practice and patient population (adult vs. pediatric). It also suggests the visual flow of information for these various roles although this remains to be proven in an upcoming validation study.

Figure 1: Oral Vignette Factor Order
Figure 2: Layout Exercise Factor Order

Figure 1 shows the relative chronological appearance of factors in an unprompted oral handoff exercise while Figure 2 shows how clinicians ordered the factors in a prompted geospatial exercise. The color coding of the dots is as follows: Light Blue: Demographics; Dark Green: Medical History; Dark Blue: Physical Findings; Orange: Medications; Light Green: Precautions; Red: Patient Status; Purple: Interpretation and Care Planning.

Integrated Clinical Decision Support Systems: Systematic Review and Classification of Online Medical Calculators

Tim A Green, BS¹, Chi-Ren Shyu, PhD¹,²,³,⁴
¹Informatics Institute, ²Computer Science Department, ³School of Medicine, ⁴Electrical and Computer Engineering Department, University of Missouri, Columbia, MO

Electronic capture of clinical data enables a variety of clinical decision support systems (CDSS). The recent proliferation of EMR’s raises the expectation that new predictive models and other types of decision support will be developed at a more rapid pace than ever before. Making clinical decision support systems available at the right time within the appropriate clinical workflow will be even more important as the amount of CDSS increase. Medical calculators are an important class of CDSS. These calculators embody evidence based medicine and are generally based on scientific literature[1]. They come in a variety of formats[2], and can even be patient facing in nature[3]. A systematic study of the integration of clinical decision support systems into EMR workflows will provide valuable insight into the best methods to deliver new evidence based medical recommendations. The proposed plan of study consists of several phases leading to a better understanding of medical calculator workflow.

Table 1 – Methods of presenting calculator results from most to least actionable probability, classification, and discrete data representing progressively less actionable results. As Table 1 illustrates, more than 75% of the calculators from each of the three sources return results in one of the bottom three result types. A prior study by Kawamoto et al. [4] indicates successful adoption is positively correlated with provision of recommendations (top three results types) rather than assessment (bottom three result types). Our findings indicate that the majority of available calculators do not fall into the categories associated with successful adoption. Perhaps development of future medical calculators should account for the presentation of results in ways that promote action and adoption, rather than simply presenting a score or calculating discrete data.

Table 2 – Correlation of experience to probability of using medical calculators

In the current phase, we surveyed clinical users and analyzed three web-based medical calculator services. Meta data were collected from these services for further analysis. Of particular interest was the discovery that the bulk of medical calculators assessed delivered results to the user in passive forms, versus active, actionable formats (Table 1). A result type of diagnosis represents the most actionable format, with recommendation, advice, and probability, classification, and discrete data representing progressively less actionable results. As Table 1 illustrates, more than 75% of the calculators from each of the three sources return results in one of the bottom three result types. A prior study by Kawamoto et al. [4] indicates successful adoption is positively correlated with provision of recommendations (top three results types) rather than assessment (bottom three result types). Our findings indicate that the majority of available calculators do not fall into the categories associated with successful adoption. Perhaps development of future medical calculators should account for the presentation of results in ways that promote action and adoption, rather than simply presenting a score or calculating discrete data.

Surveys were sent to all practicing physicians at an academic medical hospital, and data from the 108 responses have been tabulated. Findings from the survey indicate that years of experience is predictive of the probability of use of medical calculators (Table 2), with the Wald statistic for the 1-6 and >20 categories significant at α=0.05. The probability of use for years 1-6 is 0.919, whereas the probability for years > 20 is just .486. This suggests that awareness may be low among more experienced clinicians, and/or they may not see a need for these calculators. Survey free text responses suggest that experienced practitioners rely on experience, have trainees use them, or were unaware of them.

Variation Among Providers in Cost of a Knee Replacement Episode

Thomas R. Gurgiolo, MA¹, Taylor R. Pressler, MS¹, Scott Orme, PhD¹, Robert Kershner, MPT MBA², Jonathan D. Mathieu, PhD²,

¹Aver Informatics, Columbus, OH; ²Center for Improving Value in Health Care, Denver, CO

Abstract
Payment reform will include bundled payments. CIVHC is an all payer claims database within Colorado and presents a unique opportunity to compare the costs and utilization patterns within an episode of care between providers. The proposed poster will compare results of a standard Knee Replacement episode definition for Medicaid patients by provider facility. This poster presentation will examine geographic variations in cost and utilization within this episode of care.

Introduction
Bundled payments are defined as the reimbursement of health care providers “on the basis of expected costs for clinically-defined episodes of care”¹. In 2013, Medicare started a pilot bundled payment program. The Center for Improving Value in Health Care (CIVHC) is an all payer claims database for Colorado and offers a unique opportunity to examine claim and quality variances in care between different providers within the state.

Methods
The Knee Replacement episode was constructed using the Prometheus 3.6 definition. This definition provides codes and definitions for establishing which claims are part of a valid Knee Replacement episode, including which claims are considered Typical or Potentially Avoidable Complications (PAC). Episode results were compiled using the Aver Informatics platform and the results stratified by blinded facility provider. Results will be evaluated using a Student’s t-test and an adjustment for multiple comparisons.

Results
In the CIVHC data set there were a total of 2,108 valid Knee Replacement episodes, at an average cost of $10,270. Of this cost, an average of $8,173 were identified as typical costs and $2,079 were identified as potentially avoidable costs. Among providers with at least 30 episodes, the total average cost of a knee replacement varied from $6,469 to $16,222; a sample of the payer details is shown in Figure 1 below. Additional results, including analysis by region, will compare the results of this episode of care at the time of presentation.

Figure 1.

Conclusion
Using bundled payment methodology, a wide variety of total cost have been identified for Knee Replacement episodes in the CIVHC Medicaid population. Further analysis of the reasons for this variation may result in opportunities for optimizing patient care and payment reform.

Identifying Children with Technology Dependence through Use of Administrative Data

Baria Hafeez¹, Babitha Haridas², Anup D Patel²,³, Zachary Grinspan¹,⁴,⁵
¹Department of Healthcare Policy and Research, Weill Cornell Medical College, New York, NY
²Division of Pediatric Neurology, Nationwide Children’s Hospital, Columbus, Ohio
³Department of Clinical Pediatrics and Neurology, The Ohio State University College of Medicine, Columbus, Ohio
⁴Department of Pediatrics, Weill Cornell Medical College, New York, NY
⁵Komansky Center for Children’s Health, NewYork-Presbyterian Hospital, New York, NY

Background: Using electronic health information to predict health outcomes and identify high-risk patients requires mapping coded data to clinical concepts. In pediatric medicine, published algorithms can accurately map diagnosis codes (ICD-9) to clinical concepts such as “chronic illness” and “medical complexity” (Simon et al, 2014). However, little is known about how to map coded data to the concept of “technology dependence”. Technology dependent children are a medically fragile group who require (1) a medical device to support a vital body function and (2) intensive ongoing nursing care (Haffner et al, 2001). Identifying technology dependent children is important because they often benefit from improved care coordination. Here, we describe preliminary work to develop and validate an operational definition of technology dependence based on administrative data. This definition will be useful to identify children for care management and to generate variables (features) for use in predictive models. We analyzed claims data from 2011-2012 from Partners for Kids (Pediatric Accountable Care Organization for a group of children followed in a pediatric epilepsy clinic (Nationwide Children’s Hospital, Columbus, OH).

Methods: We chose four pieces of technology for our preliminary analysis: wheelchair, tracheostomy, gastrostomy tube (G-Tube), and ventriculoperitoneal shunting (VP Shunt). We identified codes for these procedures using the Current Procedural Terminology (CPT) 2012 edition and the International Classification of Diseases, Ninth Revision (ICD-9). We generated a list of patients with claims containing these codes. We then manually reviewed available patient charts to determine the validity of the codes. We created Venn diagrams to illustrate the number of patients found with (A) only ICD-9 codes, (B) only CPT codes, and (C) both. We calculated positive predictive value (precision) for each set of codes.

Results: In a group of 1996 children with epilepsy, we found 46 patients with codes for wheelchair, 17 for tracheostomy, 113 for G-tube, and 74 for VP shunt. For wheelchair and G-tube, CPT and ICD-9 codes were both helpful in finding patients. For example, for wheelchair, the CPT codes 97542, 97750, and 97760 correctly identified 15 of 39 patients, and the ICD-9 code of V46.3 correctly identified 3 of 4 patients. For Tracheostomy and VP Shunt, the CPT codes did not identify any patients beyond those found with ICD-9 codes. After excluding patients without charts available for review, the positive predictive values (precision) for the codes were as follows: wheelchair 42% (18 of 43), tracheostomy 86% (12 of 14), G-tube 86% (73 of 85), VP shunt 86% (62 of 72). The figures illustrate the codes used, the number of patients identified with each set of codes, and the number of patients without charts.

Conclusion: Administrative data can identify children with technology dependence with high positive predictive value (precision) for some technologies (tracheostomy, G-tube, and VP-shunt), but not for others (wheelchair). Use of both the CPT codes and ICD-9 codes generated a more complete list of patients than either set of codes alone.

Future Directions: We will continue to refine our definition of technology dependence. We hope to gain access to additional datasets to validate our definitions. Eventually, we would like to expand to other examples of technology dependence (dialysis, implanted insulin pump, implanted baclofen pump, etc.).
Understanding Ongoing Concerns after Implementation of Patient-Provider Messaging in the Acute Care Setting

John R. Hanna¹, Kelly McNally¹, Sucheta Ravindran MS¹ Diana Stade¹, Patricia C. Dykes, RN, PhD¹², and David W. Bates¹², MD, MSc, and Anuj K. Dalal, MD¹²
¹Brigham and Women’s Hospital, Boston, MA, ²Harvard Medical School, Boston, MA

Introduction: Bedside patient portals that incorporate patient-provider messaging functionality have much potential in improving overall communication in the acute care setting.¹ However, providers have expressed concerns about managing expectations for patient use of messaging portals. We previously identified barriers to participation by physicians.² Many were concerned with impact on clinical workflow, decreased patient interaction, and malpractice risk.² The purpose of this study is to understand ongoing concerns regarding patient–provider messaging in the context of actual patient-provider messaging data after implementing a patient portal in the acute care setting.

Methods: We measured patient-provider messaging activity on intervention units (MICU and Oncology) over a two-month period (1/1/15-3/1/15). The messaging tool was contained within a patient-centered toolkit (on a hospital-issued password-protected iPad) available at the bedside to patients and caregivers, which allowed for instant messaging to members of the care team that were on service. Care team members would receive an email notification informing them that a patient had sent them a message. We analyzed content of patient messages and grouped by major themes using a 2-person consensus approach. We conducted a 1-hour focus group consisting of 10 general medicine residents who had worked on the intervention units. During the session we reviewed intended uses of patient-provider messaging and engaged participants in discussing ongoing concerns. We then reviewed actual usage data and a preliminary analysis of patient message content with participants.

Results: Of the 231 patients/caregivers who used the toolkit, one hundred and fifty-eight sent at least one message to their providers. Thirty-six messages per week or 146 messages per month were sent to providers over the two-month period. In total, patients/caregivers sent an average of 2 messages per hospitalization. Our analysis of message content yielded the following: 19% contained health concerns, needs, and questions, 11% reported clinical status or symptoms, 11% pertained to test results or medications, 6% involved care coordination (i.e. “ICP will arrive at 12:30 this afternoon”), 26% was feedback for the care team and 42% were study related or gibberish (i.e. “I am an iPAd User”). We identified three main areas of concerns expressed by providers: 1) use for conveying emergent clinical signs and symptoms; 2) excessive patient messaging with the potential for workflow disruption due to a rapid influx of notifications; and 3) reduced face-to-face interaction with the potential for adversely impacting patient experience and quality of care.

Discussion: We observed that the volume of messages sent by patients was low and patients mostly used the messaging feature to provide non-urgent input and feedback to providers. Ongoing provider concerns regarding inappropriate and excessive use were not consistent with actual message content or messaging activity observed. Furthermore, the relative dearth of messages sent by patients argues against concerns of reduced face-to-face interactions between physicians and patients. Despite presenting these findings to providers who used the messaging tool, ongoing concerns regarding future use by patients lingered. Managing expectations regarding appropriate use of portals for messaging is essential, and could lead to further uptake by providers and ultimately increase patient utilization. An effective messaging tool could supplement and reduce the use of pagers and email in the clinical setting. By placing all members of the care team in one “chat room” and allowing clinicians to “choose” who gets notified of a message, clinicians can reduce the amount of unnecessary emails and pages and focus on improving quality of care.

Using a Socio-Technical Framework to Understand Technology Use Among Health Care Innovation Award Community Resource Planning Awardees

Saira N. Haque, PhD, MHSA, Lucia Rojas-Smith, DrPH, Debra J. Holden, PhD
RTI International, Research Triangle Park, NC

Abstract
The Centers for Medicare and Medicaid Services is supporting a number of innovations to improve community based outcomes through the Health Care Innovation Awards (HCIA). We conducted an evaluation of a subset of HCIA awardees with a focus on community resource planning to understand the impact of the innovations. A qualitative analysis was conducted using a sociotechnical framework for awardees with informatics components as part of the innovation. While the informatics components varied across awardees, studying them using a sociotechnical framework assisted in identifying themes about technology use and integration in the innovation as a whole.

Introduction
Community-based health interventions have potential to improve health outcomes of community members. In order to support innovations in service delivery or payment to improve outcomes at the community level, the Center for Medicare and Medicaid Innovation within the Centers for Medicare and Medicaid Services (CMS) funded the Health Care Innovation Awards (HCIA) Program [1]. The Community Resource Planning (CRP) programs are designed to improve health, health care and costs of care, particularly for Medicare, Medicaid and Children’s Health Insurance beneficiaries. HCIA CRP awardees all incorporate technology into their innovations to varying degrees. Eight of them have informatics as a primary focus. As part of a larger evaluation currently in progress, we sought to more fully understand how the HCIA CRP awardees with a focus on informatics (n=8) are using innovative methods to integrate people, processes, technology and context to improve community outcomes.

Methods
A qualitative analysis was conducted for the 8 awardees with an informatics focus. Data collection methods included site visits, qualitative interviews and document review. Document review was conducted of the initial grant application to the program, quarterly reporting by awardees, and documents provided by the awardee. A semi-structured interview guide was developed and tailored by role for technical, clinical and administrative staff at each awardee. Interviewees were identified in concert with awardees. The interviews were audiorecorded and notes taken. Documents were uploaded into NVIVO for coding. Thematic analysis was conducted using an interview guide based on the sociotechnical framework [2].

Results
There were a wide range of ways in which informatics was integrated into the Community Resource Planning Awardee efforts. These include support for information availability for patients across organizations, alerts for patients throughout a community, facilitating coordination, management of chronic illness, and reporting based on health information exchange. Informatics innovations were also used to support stratification of patients into risk tiers so that the work of care coordinators could be appropriately directed. Despite the wide range of informatics innovations, where were a number of common themes in its use. The degree to which the technology was aligned with organizational and community structures varied. In addition, technology and workflow integration differed among awardees. Factors that influenced informatics integration into the overall innovation included the strength of partnerships, fit between workflow and technology, technology understanding and acceptance, knowledge of the innovation by clinicians and education.

Conclusion
While evaluation work is still in progress, these activities have great promise to improve health, improve care and decrease costs. The HCIAs showcase emerging techniques for improving health through community partnerships. Findings will help communities better understand which innovative technology efforts have promise for improving community outcomes and adapt them based on their own community needs and technological capacity.

Standardized Mapping of Sensitive Data Categories  
Tiffany L. Harman RN, Rachael A. Howe RN, BSN  
3M Health Information Systems, Inc., Murray, Utah

Introduction
The widespread adoption and use of digital health information exchange between healthcare organizations to support the flow of health information to where and when it is needed is undoubtedly crucial. However, concerns arise as to what data can be shared and what data must be withheld if it is sensitive health information. Sensitive data categorization can be determined by the relevant federal and state laws, and can differ to a certain degree by state, system or use case. For semantic interoperability, data being exchanged should be encoded using standard terminologies. If the members of the sensitive data categories have been encoded using standard terminologies, then these standard codes can be automatically flagged as not to transmit (or accept). In order to evaluate whether standard terminologies provide sufficient coverage, we mapped the concept members of the following sensitive data categories: AIDS/HIV, Developmental Disability/Mental Health, and Genetic Testing. Because no one standard terminology contains all the data elements needed for sensitive health information, multiple terminologies were leveraged for this mapping. To start with, Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) was used to encode diagnosis and Logical Observation Identifiers Names and Codes (LOINC) was used to encode lab test and results. However, mapping to reimbursement terminologies such as the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM), ICD-10-CM, ICD-10 Procedure Coding System (ICD-10-PCS), Current Procedural Terminology (CPT), and Medicare Severity Diagnosis Related Group (MS DRG) was also performed, as data could also be encoded with these standards. Medications were not included in this exercise.

Method
The project had four phases: 1) evaluate each sensitive data category to identify member concepts; 2) identify the standard terminologies applicable to the concepts (based on the concept definition); 3) map each member concept to one or more standard terminology codes, and 4) implement the mapping in a terminology server to provide a practical maintenance solution.

Results
6771 standard codes were mapped to the members of the sensitive data categories listed above. Of these, 40% of the coverage was represented by SNOMED CT and 32% of the coverage was represented by LOINC. Note that a concept can be a member of more than one sensitive data category. There are 34 unique standard codes that are in different sensitive data categories. There are 2 SNOMED CT codes and 2 LOINC codes that are in both the AIDS/HIV and Developmental Disability/Mental Health sensitive data categories, and there are 31 SNOMED CT codes and 31 LOINC codes that are in both the Developmental Disability/Mental Health and Genetic Testing sensitive data categories (see figure 1).

Conclusions
Identifying standard codes that correspond to sensitive data can help to set up automated flagging to prevent unauthorized distribution. However, there are implementation challenges. There is no standardized list of concepts and standard codes that constitute sensitive data, resulting in variability in determining which data should not be shared. Even with consensus, there could be false negatives. For example, patient data may have the wrong standard code assigned in the electronic health record (EHR), or the EHR may not have a standard code at all. Resolving data issues requires collaboration to ensure data integrity, proper use case and continuous improvement. Nevertheless, creating a custom categorization and encoding sensitive health information to standard terminologies is a useful and usable first step.
Before-after implementation of the sniffer for the detection of failure to recognize and treat severe sepsis

Harrison AM, BS; Thongprayoon, C, MD; Park JG, MD; Daniels CE, MD; Clements CM, MD, PhD; Goyal DG, MD; Elmer JL, DNP, APRN, CNS; Gajic O, MD, MSc; Pickering BW, MB, BCh, MSc; Herasevich V, MD, PhD
Mayo Clinic, Rochester, MN

Background: In 2013, the US Agency for Healthcare Quality and Research ranked septicemia as the most expensive in-hospital condition in the US, based on 2011 data.1 Despite increased understanding of this problem,2 previous sepsis detection and alert systems have failed to demonstrate improvement in clinically meaningful outcomes.3 The objective of this study was to measure the impact of the automated, electronic sepsis sniffer on compliance with the 3-hour Surviving Sepsis Campaign (SSC) bundle elements.

Methods: We recently developed and validated a sniffer for the detection of failure to recognize and treat severe sepsis.4 Beginning 01/14/2015, the sepsis sniffer (suspicion of infection, Systemic Inflammatory Response Syndrome, and organ dysfunction components) was implemented in the medical ICU (MICU) at Mayo Clinic Rochester in AWARE—a patient-viewer and clinical decision support tool designed at Mayo Clinic to reduce risk of error and already in routine use in the MICU5—as well as in the Emergency Department (ED). Implementation occurred after focused provider training and presentations. Using METRIC Data Mart,6 a relational database and near-real time duplicate of the complete hospital EMR at Mayo Clinic, data on 3-hour SSC bundle element compliance for patients before implementation of the sepsis sniffer in the MICU (January through March 2013, N=98) was compared to MICU and ED data after implementation of the sepsis sniffer (January 14th through March 2015, N=60). As some ED visits result in no hospital admission or no admission to the MICU, these outcomes are not present for all patients in the “after” cohort. Average time to completion was calculated as: “Time of bundle element completion” minus “Time of sepsis detection”. Thus, negative results indicate compliance before detection.

Results: Overall percent completion of the 3-hour SSC bundle was increased after tool implementation. Overall average time to bundle completion was reduced for all 4 elements. Detailed results are in the following Table.

<table>
<thead>

Meal-Camera System to Support Nutritional Tele-Consultation for Diabetics

Masayuki Hashimoto1, MSc, PhD, Umi Nakamura1, Miki Akiyama, MSc, PhD2, Toru Takebayashi, MD, MPH, DMSc2, Marino Oshima3, Tomoki Kumegawa3, Hitomi Imachi, MD, PhD 3, Koji Murao, MD, PhD3

1KDDI R&D Labs., Saitama, Japan; 2Keio University, Tokyo/Kanagawa, Japan; 3Kagawa University Graduate School of Medicine, Kagawa, Japan

Abstract
We propose a communication tool for connecting diabetic outpatients and hospital’s medical staff such as dietitians and doctors. This system supports nutritional tele-consultation based on meal images taken by patient’s smartphone. Patients easily send images of their meals with applications installed in smartphones. Dietitians use computers and guide the patients remotely based on the images. Clinical study with 20 patients show that patients’ weight and HbA1c improved in the most cases.

Introduction
In order to prevent deterioration in diabetic’s condition, it is essential to guide their nutrition consumption every day. It is difficult for hospital medical staff to observe outpatients’ daily diet, thus some patients often do not follow nutritional guidance that they should follow. This causes serious deterioration in their condition. Therefore, we developed “Meal-camera system” to support daily nutritional tele-consultation. Its smartphone app for patients is easy to use and its web interface for dietitians is designed for supporting quick nutritional evaluation of patient’s meal. Nutritional tele-consultation is effective for motivation to continue health program[1]. Here we show the outcome in clinical study with diabetic outpatients.

Methods and Results
The system consists of a smartphone with an original application, an image-storage database server and PC for dietitians in a hospital. Patients take pictures of all meals (including snacks) and send images using smartphones. Hospital dietitians reply comments once or twice a day using PC. Dietitians and patients can communicate with each other using SMS function in this system. In our clinical study, 20 diabetic patients received this nutritional tele-consultation. The patients’ weight and HbA1c improved in the most cases. Followings are details of two cases of them:

[Case1] A pregnant woman with diabetes type 1, who miscarried previously due to hyperglycemia, became pregnant. Too much fear on hyperglycemia leads her to inject insulin excessively. That caused failure in controlling her blood sugar. Thus we started tele-consultation using the proposed system. After that, her blood sugar became stably controlled. She gave birth without any problems at last.

[Case2] A woman with diabetes type 2 took medicine in obesity treatment, but it was not effective. Furthermore, it was difficult for dietitians to assess her daily intake by interviews. Accordingly, we started nutritional guidance using the system. After that, the patient worked on dieting. This caused improvements in both losing weight and HbA1c shown in Figures 1 and 2.

Conclusion
We developed “meal-camera system” to support daily nutritional tele-consultation. In clinical study, 20 diabetic outpatients consulted hospital dietitians. The results show effectiveness of the tele-consultation using this system.

Conducting health insurance surveillance with electronic health records

Brigit Hatch, MD MPH1; Carrie Tillotson, MPH1,2; Megan Hoopes, MPH2; Miguel Marino1, PhD; Rachel Gold, PhD MPH3; Jennifer E. DeVoe, MD DPhil1,2

(1) Oregon Health & Science University, Portland, Oregon, USA; (2) OCHIN, Inc, Portland, Oregon, USA; (3) Kaiser Permanente Northwest Center for Health Research, Portland, Oregon, USA

Purpose: Under the Affordable Care Act (ACA), Americans have new access to health insurance, yet challenges remain to successfully obtaining and maintaining coverage. The Electronic Health Record (EHR) presents new opportunities for patient-centered primary care homes to track patients’ insurance coverage and assist with enrollment and retention. We aimed to utilize EHR data from a national network of community health centers to monitor insurance status over time and identify factors associated with uninsurance.

Methods: Using EHR data from the OCHIN network of over 300 clinics in 16 states, we conducted a retrospective cohort study of all adults seen for primary care at an affiliated clinic from 2012-2013. We described the population and its utilization of primary care services, monitored changes in clinic-identified insurance status over time, and used generalized estimating equation (GEE) logistic regression with a robust sandwich estimator to identify factors associated with uninsurance.

Results: The population (n=279,654) was predominantly female (58%), white (77%), non-Hispanic (71%), and living with incomes beneath the federal poverty line (57%). At their first visit during the study period, the majority (41%) were uninsured, 39% had Medicaid, 16% had commercial insurance, and 4% had other insurance types. Among patients with no insurance at their first visit within the study period (n=114,000), 50% continued to be uninsured for every subsequent visit during the study period, while 13% gained insurance, and 36% had no further visits during the study period and therefore unknown insurance status. Among patients with Medicaid at their first visit (n=109,431), 68% maintained insurance at every subsequent visit, while 7% had lost insurance, and 24% had no subsequent visits. Among patients with commercial insurance at their first visit (n=44,420), 63% maintained insurance, 6% lost insurance, and 31% had no further visits. Compared to patients with Medicaid, factors associated higher odds of uninsurance included female gender, age >25, Hispanic ethnicity, income above the FPL, and rural residence (p<0.01).

Conclusions: This study identifies a large group of patients who continue to seek care at community health centers despite ongoing lack of health insurance and confirms previous studies highlighting the social vulnerability of this population. Now that many of these patients can access health insurance under the ACA, there is critical need to develop systems to support patients in obtaining and maintaining coverage. The electronic health record presents new opportunities for identifying and tracking insurance status within a patient-centered primary care home. Currently, the EHR can only track insurance status in relation to each office visit. However, EHR-based tracking tools could capture automated data and support health insurance outreach from within the patient-centered primary care home both during and between patient visits. As the delivery system moves toward care beyond office visits and as more people than ever have access to public insurance, such methods hold promise for assisting vulnerable populations with the challenge of obtaining and maintaining health insurance.
Mapping Hospital Infections to Inform Quality Improvement Interventions

Courtney L. Hebert, MD, MS¹,², Tara B. Borlawsky, MA¹
¹The Ohio State University, Department of Biomedical Informatics, Columbus, OH; ²The Ohio State University, Division of Infectious Diseases, Columbus, OH

Abstract
Hospital acquired infections (HAIs) are the target of federal initiatives to improve quality of care. HAI surveillance is often performed manually, and reported using tables and charts. We assessed the feasibility of automating an HAI identification algorithm, and displaying the results on a hospital map to provide geospatial context.

Introduction
Reducing hospital-acquired infections (HAIs) has become a leading focus of quality improvement efforts nationwide. Despite the growth of electronic health records (EHRs), surveillance data used to inform these efforts are often manually abstracted. This takes significant time and effort on the part of safety and quality staff, and results in outdated data. Public health surveillance data are often displayed on maps in order to understand the potential transmission and outbreak pattern of a public health concern, however, when hospital surveillance data are shared between safety and quality staff they are most commonly presented in tabular format or line graphs. In fact, for many infectious diseases the geospatial distribution can be extremely important for evaluating transmission between patients or for potentially identifying unit-related differences in care-processes. As part of an ongoing effort, we propose to create a hotspot map of the hospital, displaying the location of each HAI, in order to identify high risk areas and inform targeted interventions to decrease HAIs (i.e. unit specific training).

Methods
The main objectives of this project are to: (1) create an algorithm for normalizing and standardizing the organisms to which a catheter-associated urinary tract infection (CAUTI) is attributed, and (2) display the location of these events on a map of the hospital. Data on all hospital-acquired CAUTIs reported per the Centers for Disease Control National Healthcare Safety Network definition¹ at The Ohio State University Wexner Medical Center over a 1-year period were collected along with clinical data including microbiology and locations. To develop an automated microbiology algorithm we also collected 3 months of general microbiology results. These were parsed, and annotated with SNOMED-CT codes to allow us to systematically identify organism type, including genus, species, Gram stain and colony counts. The location of attribution of each CAUTI was displayed on a map of the hospital unit as a dot, color-coded to indicate type of organism in order to additionally track potential organism transmission. The dot appears on the map at the date of onset, and is removed on the date of transfer out of the unit.

Results
Of >50,000 microbiology results, 1195 were identified as positive. Using a Perl script to implement a set of regular expression parsing and lexicon matching rules, SNOMED-CT codes for organism and genus were automatically assigned to 1143 organisms (983 bacterial and 160 fungal). While the algorithm has yet to be formally evaluated, an informal assessment by an infectious disease clinician (CH) indicates that it is highly accurate. The microbiology parsing algorithm was then applied to the CAUTI data. The location of each CAUTI was displayed on a map of the hospital, labeled with infection type. The CAUTIs were not uniform across hospital units, but clustered in units with higher risk patients. The distribution of organisms and temporal association between CAUTI events were easily visualized.

Discussion
In this study we were able to successfully parse microbiology reports and show that a map of surveillance data provides useful context, not currently available in tabular reports. Future work includes a formal evaluation of the microbiology parsing algorithm, development of an automated CAUTI identification algorithm and creation of a real-time, interactive map of the hospital displaying multiple types of HAIs and infecting organisms over time, which could be used by infection preventionists to evaluate potential outbreaks and inform their interventions.

Identifying ECG Features in Congenital Heart Disease Using Variants of Dynamic Time Warping

Emily P. Hendryx, M.A. 1, Craig G. Rusin, Ph.D. 2, Beatrice M. Riviere, Ph.D. 1
1Rice University, Houston, Texas; 2Baylor College of Medicine, Houston, Texas

In the clinical setting, bedside monitors provide physicians with large amounts of physiological data. One of the signals presented on the screen is the electrocardiogram, or ECG. Each feature of the ECG corresponds to a specific part of the cardiac cycle, and to the well trained eye, an ECG can provide key information about a patient’s clinical status. Because of their diagnostic utility, the primary goal of this research is the automatic identification of ECG features in congenital heart disease. These features can then in turn be used to develop real-time predictive models to help doctors make informed treatment decisions.

With data from Texas Children’s Hospital, our work focuses on physiological signals from patients with hypoplastic left heart syndrome (HLHS). Patients with this congenital heart disease have an underdeveloped left ventricle, resulting in a lack of blood flow to the rest of the body. Because these are sick patients, their ECG signals do not look like the typical textbook ECGs and seem to vary widely. Adding more complexity, data is usually simultaneously recorded from four ECG leads, each lead providing information from a different angle. Our goal is to effectively sort the large amounts of ECG data available into classes based on heartbeat morphology and then identify ECG features based on their classification.

To approach this problem, we first combine the different ECG lead information into one signal, the vectorcardiogram magnitude, reducing the number of individual beats to be analyzed. In clustering the data, variations of dynamic time warping are used in conjunction with k-medoid clustering. Dynamic time warping (originally used in speech recognition) allows for the comparison of two signals that might have similar features, but these features are shifted in time. Hence, it is a measure that lends itself readily to ECG feature identification. The methodology is tested on a set of synthetic ECG data and on a set of approximately 4000 patient heartbeats with promising preliminary results.

With the identification of the representative morphology classes found in the data, dynamic time warping then provides a means for mapping known features in a pre-labeled heart beat to similar un-labeled heart beats. While the application of dynamic time warping to ECG data is not new, there appears to be little literature based on pediatric data – especially data from patients with congenital heart disease. This work addresses this gap in the literature and provides a stepping stone for the development of ECG-based predictive models for the pediatric population.

This research was funded by a training fellowship from the Keck Center of the Gulf Coast Consortia, on the Training Program in Biomedical Informatics, National Library of Medicine (NLM) T15LM007093, 2014-2015.

Using MetaMap to Analyze Which Linguistic Concepts in an Imaging Study Indication Make it Helpful to a Radiologist

Andrew Herzik, MD1, Joshua M. Pevnick, MD, MSHS2
1LAC+USC, Los Angeles, CA; 2Cedars-Sinai, Los Angeles, CA

Abstract
For reading radiologists, order indications improve interpretation. We used UMLS MetaMap to analyze which linguistic concepts in order indications are most helpful to radiologists. We analyzed indications from 200 abdomen/pelvis CTs, and found that the following concepts were most associated with higher indication quality: “Modifying concepts” (p=0.01), “Findings” (p <0.0001), “Disease/Syndromes” (p=0.01), and “Ideas or Concepts” (p = 0.01). This knowledge could be used to help improve providers’ indication quality.

Background: Order indications for radiology exams provide valuable clinical context to reading radiologists; this, in turn, facilitates more successful interpretation. Unfortunately, there is substantial variation in the quality of radiological order indications. We are aware of studies analyzing how structural characteristics, like computerized physician order entry (CPOE), affect indication quality. However, we sought to learn which linguistic concepts in the indication would be most helpful to a radiologist, and were unaware of any prior research in this area.

Methods: We conducted an IRB-approved, retrospective analysis of de-identified radiological order indications from a large university-affiliated hospital. We obtained order indications from 200 randomly selected inpatient CT abdomen/pelvis studies ordered between January 1st, 2012 and June 30th, 2012. 100 indications were from a pre-CPOE environment and were handwritten on paper that was otherwise blank. The remaining 100 were ordered with CPOE that included study-specific buttons and the option of including unstructured text.

To extract linguistic concepts, we used the text mining UMLS Metathesaurus MetaMap to map order indications. We compared MetaMap results to two radiologists’ independent implicit Likert scale ratings, which we used as a reference standard scale of indication quality. Two radiologists with extensive experience reading CT scans of the abdomen/pelvis independently rated each order indication on a 5 point Likert scale (“The following indication helps me successfully interpret the CT abdomen study”). We hypothesized that MetaMap categories “location concepts” and “temporal concepts” would be most predictive of high scoring indications.

Each order indication was mapped using MetaMap 2014 on default settings (data source: 14/15 Transition – 2014AB, data version: USAbase, data model: strict). In the instance of multiple concepts, we used clinical judgment to determine the predominant concept. We also used clinical judgment to overrule incorrectly identified concepts (e.g. spelling errors erroneously identified as concepts), which were then discarded. We used linear regression to examine the effect of various language concepts on the reference standard score.

Results: We analyzed 200 CT abdomen/pelvis order indications. We generated a final model using stepwise regression. In our final model, use of “Temporal concepts” (p=0.025), “Modifying concepts” (p=0.01), “Signs and Symptoms” (p=0.032), “Findings” (p<0.0001), “Disease/Syndromes” (p=0.014), and “Ideas or Concepts” (p=0.01) were significantly associated with higher Global Implicit Scores, (model R²=0.33).

Discussion: Understanding which linguistic concepts are most helpful could be used by ordering clinicians to improve indication quality. Furthermore, it could be used by designers of electronic health records to choose which text to offer on study-specific indication buttons. Simple modifying concepts such as “severe” or “worsening” for example, if attached to basic findings would add over half a point in the quality of indication. Electronic health records could potentially provide automated real-time feedback to ordering clinicians regarding their indication quality. Additional research is required to understand how variables like CPOE implementation or physician specialty shape linguistic patterns. Nonetheless, this study demonstrates the potential utility of data mapping with MetaMap to inform and improve communication between physicians.

Electronic Health Record Audit Logs: An Alternative Approach to Workflow Analysis

Authors
Annemarie G. Hirsch, PhD, MPH1, Virginia R. Lerch, MPH2, J.B. Jones, PhD. MBA3, Walter F. Stewart, PhD, MPH1
1. Center for Health Research, Geisinger Health System, Danville, PA; 2. Institute for Advanced Application, Geisinger Health System, Danville, PA; 3. Research Development and Dissemination, Sutter Health, Walnut Creek, CA

Background
As described in Sittig and Singh’s socio-technical model for studying health information technology, successful development, implementation, and evaluation of health information technology interventions in clinical settings are dependent upon the ability to assess and adapt to clinical workflows.1 Consistent with this model, studies of electronic health record adoption have revealed the barriers presented by incompatible workflows and the success associated with thorough workflow analysis prior to HIT implementation. The pace at which new HIT is becoming available in clinical care settings is increasing. The HITECH Act has triggered a rapid increase in EHR adoption and now EHR vendors such as EPIC are beginning to make EHR integrated apps available to health systems. Traditional methods of workflow analysis, such as time and motion studies, will be unable to keep pace with what is anticipated to be a rush of new technology in clinical care settings, putting at risk the ability to successfully integrate these potentially beneficial technologies while also hindering assessment of the impact of these technologies on clinical care.

The EHR audit file, a log that tracks user activity in the EHR, is largely an untapped source of data that provides an alternative to resource and time intensive methods of workflow analysis. The EHR audit log file maintains a time-stamped audit log of transactions when a patient record is in use. The audit log tracks users (i.e., nurses and providers who log in to patient record), actions (i.e., “view”, “accept”, “cancel”, “print” and “exit”), and the EHR modules in which the actions take place (e.g., encounter, medication lists, orders, etc.). Previous efforts have used audit files to measure clinical documentation time, detect patterns of EHR use, and monitor user activity—we describe another method of utilizing the audit file to understand clinical workflows.

Methods
We used the audit file data from the Geisinger Health System (GHS) EHR to better understand the workflow of primary care visits in family practice clinics from the time the patient checks in to when the patient checks-out. Specifically, we used retrospective audit file data to determine what health care providers are involved in primary care visits; in what order the providers work with patients; how much time providers spend with the patients; and how much time patients wait during a primary care encounter.

Results
Encounters were included in the analysis if they were for primary care patients; took place in one of the 30 GHS family practice clinics; had at least one action recorded in the audit file between check-in and check-out; and took place between January 1, 2009 and June 30, 2011. There were 1,212,446 encounters in the 30 GHS family practice clinics between January 1, 2009 and June 30, 2011. To reduce the processing time and computational memory required to analyze more than 1 million encounters, we randomly selected 30 dates on which at least one of these encounters occurred using simple random sampling. Applying the eligibility criteria to the encounters scheduled on these 30 dates reduced the number of encounters to 36,437 across 26 separate family practice clinics, 3.2% of all family practice encounters during the study period.

On average, patients spent 5 minutes with the nurse and 16 minutes with the provider during these encounters. Patients spent an average of 14 minutes in the waiting room, 11.6 minutes in the exam room waiting for the provider, and 9.7 minutes waiting to check-out of the encounter.

Conclusion
Our data confirm the findings of prior work that used survey and direct observation to measure duration of primary care visits.2 The ability to study the audit data retrospectively makes this low cost method of workflow analysis a viable alternative to the use of more traditional methods of workflow analysis, such as time and motion studies, which require a prospective study design and need advanced notice of pending policy changes in order to evaluate the impact of these changes. The longitudinal data available in the audit files can also be linked to encounter-level and patient-level clinical data to offer unique insights on the impact of the frequent and rapid changes in operations and health policy.

‘Smart Snack Box’ System for Recording Snacking Behavior

Teruyoshi Hishiki, MD, PhD¹, Hiroki Yasui, MD, PhD², Yoshiko Matsunaga, RN, PhD¹, Takuro Tamura³

¹Toho University, Tokyo, Japan; ²Nagoya University, Nagoya, Japan; ³LINE Co., Ltd, Tokyo, Japan

Abstract
A convenient method of identifying individual snacking patterns would be helpful in dietary consultations. Here, we report an ongoing project to develop a ‘Smart Snack Box’ that records the timing of snacking behavior. The apparatus contains sufficient snacks for an individual to eat during the day, and it electronically detects and records each opening of the lid. We plan to test the system on healthy subjects.

Introduction
Studies of the circadian rhythm in humans have revealed the impact of the frequency and timing of meals on the metabolic state, which indicates that eating patterns have an influence on health and disease¹. The effects of snacking patterns on body weight and diabetes control have also been investigated². To apply this knowledge, it would be useful to profile the frequency and timing of snacking in individual subjects. Here, we report the ongoing development of a ‘Smart Snack Box’ that records the timing of snacking behavior.

Methods
The box consists of a container with a hinged lid, a microcomputer, and a controller computer. A Hall effect sensor is positioned on the side wall and connected to the microcomputer, and a magnet is positioned on the lid such that it almost touches the sensor when the lid is closed. The microcomputer sends an ‘OFF’ signal to the controller computer while the lid is open. While the lid is closed, the sensor generates a voltage and the microcomputer sends an ‘ON’ signal to the controller computer. The accuracy of the sensor was checked while opening and closing the lid 100 times prior to the full experiment.

The setting of the experiment is as follows. The intended subjects are three male and three female office workers to be recruited by the authors. We will record their snacking behavior, using their declared snack food, over three working days. Before the system is activated, the user will fill the box with sufficient snacks for consumption during the working day. The user is free to open the box and remove a snack whenever he/she likes. Timestamps of the snacking behavior will be logged on the computer, and snacking patterns over the course of the day will be extracted for each subject. We will discuss the results of the analysis with the participants, focusing on whether they were aware of their eating patterns and why they eat snacks at certain times of the day.

Results and Discussion
The sensor correctly detected the opening and closing of the lid for each of the 100 repetitions. There are few methods for collecting data on eating behavior that do not rely on self-reporting, except for a technique for detecting chewing. A limitation of the proposed method is its inability to record the quantity of snacks removed. This could be overcome by integrating a scale into the snack box. Collection of individual snacking patterns, as well as recording of physiological information such as heart rate or blood pressure, would enable the ‘Smart Snack Box’ to control snacking behavior by directing the user to change their behavior at the time they are likely to reach for a snack.

Conclusion
We have developed the ‘Smart Snack Box’ as a method of recording snacking behavior without self-reporting. The next step of testing is a trial to be conducted with healthy volunteers.

References
Introduction: Clinical practice guidelines have a slow rate of adoption in medicine. Clinicians need timely and widespread dissemination of evidence to guide clinical practice. Really simple syndication (RSS, also called rich site summary), a method ubiquitous to news outlets, could also be used to circulate journal articles.

Methods: In a systematic review, we examined the use of RSS by medical professionals. We reviewed several databases (LISTA, Pubmed, and Ovid(Medline/CINAHL/Psych/Health&Bus) with search inclusion criteria of the following keywords: “RSS, rich site summary, really simple syndication” as well as MeSH term Webcasts (where RSS topic is found). An article was excluded if it was not written in English, if the paper did not cover RSS feeds, or if the paper was not about Medicine.

Results: Our review initially found 1610 articles, of which 1430 were excluded as duplicates, irrelevant to the topic or by abstract review. In full text screen of the remaining 183 articles, 50 more articles were excluded for various reasons. For this review, we included 130 articles, and we found several categories of use within medicine, like nursing, veterinary medicine and health librarian education. A few articles explained RSS and its benefits to medical professionals. Of the articles screened, many were published by non-medical sources (i.e., Fortune or Forbes magazine) or were opinion pieces in specialty journals lacking significant evidence or rigor.

Conclusion: We found a number of different articles with explanations of how medical professionals use RSS. Most of these are found without descriptions on how to set up a personalized feed, and are more anecdotal in nature. We have summarized the guidance of these articles to help clinicians set up RSS feeds. This step by step guide will direct the clinician to different websites based on interests and will help them navigate web pages of journals and information sites to find sources to add to their feeds. Once added, the feeds will become more personalized, and will serve as a comprehensive platform to help clinicians use RSS in effective and relevant ways.

Introduction to the Problem and Specific Purpose of Research

Price transparency has been proposed to decrease rising healthcare costs.1 Large interventions like Aetna’s Member Payment Estimator and Castlight’s tools for WellPoint show price transparency to be a growing field in health information technology (HIT).2 However, no systematic review of price transparency existed. Our new systematic review explores how displaying price information impacts the number and cost of services selected by both patients and physicians.

Methodology

Following PRISMA criteria, we searched both PubMed and the Web of Science Core Collection for articles on price transparency, using keywords including “cost,” “charge,” “transparency,” “display,” and “electronic health record.” We limited our search to publications that are written in English, have full text versions available, and contain an original empirical study on patient or provider access to price information.

Results

The initial search yielded 2098 citations, of which 69 met criteria for a full-text review. Ultimately 11 articles met criteria for inclusion in the final analysis. For the eligible publications, study participants were primarily clinicians (9 of 11 studies, or 82%) although two articles described patient-facing price displays. Clinical environments included a range of inpatient, outpatient, and Emergency Department settings in both academic and non-academic centers. Price displays covered a breadth of medical tests including radiology imaging, laboratories, and others.

The two patient studies suggest patients made choices balancing cost and quality, and that price transparency decreased imaging and laboratory costs by a mean of 13%. The nine clinician studies allowed more comprehensive analysis. All clinician studies found a reduction in number of orders, with a mean decrease ranging from 4.5% to 27%. The mean total cost of orders decreased from 3% to 37% with varying statistical significance in those articles; however, all articles measuring cost savings found statistically significant savings in at least one category of medical tests.

Discussion

Nearly half (5 of 11, or 45%) of empiric price transparency articles were published in the last 2 years, indicating the timely relevance of this topic, but also limiting some power of our review. The overall cost savings suggest future research is warranted, and the limitations gleaned are particularly relevant to shape future research. Most studies evaluated the price transparency impact for six months or less, so future longitudinal studies to assess the long term cost impact would be valuable. Also, health outcome measures were assessed in only two of the publications and revealed mixed results, so future research should ensure quality metrics remain high even if costs decrease. Also, due to the range of clinical environments, participants and medical tests studied, further research is indicated—particularly to explore the growing field of patient-centered price transparency.

Conclusion

Price transparency is an HIT tool proposed to lower healthcare costs. Our systematic review reveals cost savings in a range of studies, and suggests further research is warranted to explore this growing field.

Informational Content of Verbal Handoffs in Emergency Care

Jan Horsky, PhD,1,2 Edward H. Suh, MD,3,4 Osman Sayan, MD,3,4 Vimla Patel, PhD5

1Brigham and Women’s Hospital, Boston, MA, 2Harvard Medical School, Boston, MA  
3New York-Presbyterian Hospital, NY, 4Columbia University Medical Center, NY,  
5New York Academy of Medicine, NY

Introduction
Handoff of care between shifts is a known risk factor for medical error and adverse events.1 Physicians transferring the care of patients need to succinctly characterize the course of care and convey it to the incoming clinician. Verbal communication is often limited to a brief narrative encompassing laboratory results, significant events, assessments and other often complex data that need to be presented as interconnected events that can be accurately interpreted. Sufficiently detailed presentation will allow the new team to continue care without interruption. Interventions to reduce misinterpretation and loss of facts often involve a combination of training, standardization and the use of structured forms. However, large variations in illness complexity and diagnostic certainty between patients in the same handoff process are intrinsic to emergency care and make uniform and inflexible forms of support unlikely to be effective. Research suggests that handoffs discussions also afford the opportunity to consider alternative viewpoints, correct mistakes and propose new tests or interventions.2 Our objective was to observe discussions during handoffs and analyze how uncertainty affects the content of presentations and to test our assumptions about the relationship between uncertainty levels, clinical complexity and different needs of support for physicians describing patient cases.

Methods
We observed and recorded clinicians during eleven shift changes. Groups of two to three outgoing residents presented between seven and twenty-two patient cases to an incoming attending physician in an ED of a large urban hospital. Recordings containing conversations about 150 patients were transcribed and categorized along dimensions of diagnostic uncertainty and fit with illness script. We operationalized uncertainty along three axes with 3- and 2-point scales. The constructs were derived from concepts in medical education and clinical care and were developed iteratively in a series of meetings and conversations. Patient narratives in each category were then analyzed for levels of descriptive detail in history of illness and physical exam (HPI PE), diagnostic findings and detail of ED course.

Results
About a half of handoff narratives in each category contained only minimal descriptive detail: 53% of HPI, 47% of diagnostic findings and 55% of ED course information. Detailed descriptions of HPI were communicated for 16% of patients, 3% of diagnostic findings and 12% of ED course information – the smallest proportions in each category. There were no descriptions of diagnostic findings for 31% of cases and 16% of ED course. Diagnostic uncertainty was classified into three levels: 1 - Clear presumptive diagnosis (most confident), 2 - Narrow differential and 3 - Unclear (least confident). The most frequently observed level was 2 (51%). For 13% of patients the diagnosis was Unclear. Fit to script was determined as: 1 – typical (41%), 2 – Variant of a typical problem (19%) and 3 – No recognized fit (9%). Comparing content across the categories of uncertainty we found that levels of descriptive detail were largely determined by confidence in diagnostic judgment. As uncertainty increased, physicians provided more information in handoff presentations. Statistical analyses showed significant difference between groups classified by uncertainty.

Conclusion
When patients do fit well onto an established process script, physicians do not see value of adding additional detail to the handoff. Effective electronic support tools should allow for variations in complexity and diagnostic certainty.

Stakeholder Perspectives on Policy Implications
Post the Conclusion of the State HIE Program

Lauren Hovey, MA1, Petry Ubri1, Prashila Dullabh, MD1
1NORC at the University of Chicago, Bethesda, MD

Research Objective
Since the passage of the Health Information Technology for Economic and Clinical Health (HITECH) Act, and with it the creation of the State HIE Program and other health information exchange (HIE)-supportive initiatives, adoption of electronic health records (EHRs) has grown significantly and HIE has expanded. Following the conclusion of the State HIE Program, there are a number of opportunities at the state and federal levels to continue enabling HIE services.

Study Design
We draw these policy implications from three evaluation activities: a qualitative, in-depth assessment of eleven states consisting of site visits; semi-structured stakeholder discussions in five states, and 60-minute summative interviews with key informants with diverse perspectives on HIE. From these activities, we gleaned important lessons learned and suggestions for maintaining and expanding HIE following the conclusion of the program. For the case studies, NORC held discussions with more than 100 individuals in eleven states. For stakeholder discussions, NORC had conversations with forty-five stakeholders in five additional states. Informants included providers, payers, vendors, Medicaid and Public Health personnel, and state program leadership, among others. The summative key informant discussions included 22 thought leaders across state, federal, and private sectors.

Principal Findings

- States play an important role in leadership and coordination, particularly in convening stakeholders, policy development, and needs assessment, which will be relevant to future stages of meaningful use and health care reform.
- There is a critical need for strong, ongoing federal support related to governance, technical standards, and interoperability.
- There is a need for alignment of HIE efforts across federal agencies to leverage HIE investments. The healthcare system’s HIE goals require the development and use of consistent technical standards for information flow which could potentially be pursued by an aligned “policy push” with federal incentives for standards of information.
- A provider- or federal-led effort to obtain buy-in from HIE developers for overarching HIE goals may be warranted and needed to change perceptions of interoperability.
- There is a need to assess how technical solutions evolve in different markets, to develop and disseminate best practices, and to develop governance and oversight requirements at a state and national level. This is a responsibility best shared between state and federal leaders.
- Organizations should monitor findings and best practices for sustainability from existing federal and state level initiatives leveraging pay-for-performance models.

Conclusions
The results suggest that federal- and state-level entities have important roles to play in the next phase of HIE. Continuing the expansion and maximizing the utility of electronic data exchange will require their leadership and guidance in terms of policies, data standards, and best practices. Robust and sustainable HIE also requires participation, buy-in, and needs assessments from healthcare organizations, providers, and developers.

Implications for Policy, Delivery or Practice
HIE sustainability will be a collective effort with important roles for stakeholders and added support from a new generation of initiatives, such as the Health Care Innovation Awards and State Innovation Model funding.
Evaluation of a Local Terminology to SNOMED CT Crosswalk

Rachael Howe, MSN, RN, Tiffany Harman, RN, Pat Wilson, RT(R), CPC, PMP, Lee Min Lau, MD, PhD 3M Health Information Systems, Inc., Murray, UT

Introduction: The Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) is a clinical terminology used to represent clinical concepts in healthcare for the purpose of increasing interoperability between electronic systems. The goal of this study was to evaluate the crosswalk created between two terminologies, the target being SNOMED CT and the source being a local terminology, to see if the mapping was accurate, so that data encoded with the local terminology could be translated to SNOMED CT for data exchange. The local terminology contained multiple clinical concepts across the full spectrum of healthcare, effectively resulting in the need to utilize all of SNOMED CT for comparison.

Method: There were 3 phases in this project: analysis of the local terminology content, examination of the relationships between each source and target concept, and evaluation of findings. Analysis consisted of studying the documentation provided along with the data to understand how and why the data was mapped. The local terminology content was then assessed to understand how the relationships were determined. Next, each concept to concept association was examined in depth. Finally, the overall data was reviewed for inconsistencies and gaps in concept coverage and meaning, and to establish metrics.

Results: The crosswalk utilized 62 relationship types, of which 59 mapped to attributes (which are in turn members of the “linkage concept” high level domain) in SNOMED CT. However, two of the relationship types used in the crosswalk mapped to the same SNOMED CT concept ID, thus only 58 SNOMED CT attributes were used in the crosswalk. In addition, 3 new relationship types (not found in SNOMED CT) were created for the crosswalk. The documentation provided with the data did not indicate the reason for each relationship type nor how they were to be used. Thus each concept-relationship-concept triplet was evaluated solely on the definition implied by the description or designation, the majority of which were understandable. There were a few instances, however where semantic drift may have occurred. For example, the SNOMED CT attribute of ‘Is A’ (SNOMED CT ID 116680003) was altered to “Narrower than (IS A)”, which may have a negative impact on the accuracy of the local concept mapping to SNOMED CT. This is especially significant since this relationship type accounts for the largest proportion of mapping rows (over 39%, or 166,125 out of 424,488 rows). Another example is the inverse relationship of ‘Broader than’, which was not derived from an existing SNOMED CT attribute, is a misnomer for a grouping of local terms that have a single property or concept component in common (see Table 1 below).

<table>
<thead>
<tr>
<th>LOCAL CONCEPT</th>
<th>RELATIONSHIP TYPE</th>
<th>SNOMED CT PREFERRED TERM</th>
<th>SNOMED CT ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retina</td>
<td>Broader than</td>
<td>O/E - no retinopathy</td>
<td>390847009</td>
</tr>
</tbody>
</table>

Table 1: Example of a ‘Broader Than’ Relationship

Conclusion: Our final analysis showed that although a lot of local terms could be crosswalked to SNOMED CT through the mapping created, there were cases where the relationship types applied were not consistent in meaning and usage. Existing informatics principles should be considered and documented when establishing a new crosswalk or map to ensure that it is meaningful, useful and reproducible. This particular crosswalk would require additional review and revision to improve accuracy in mapping from the local terminology to SNOMED CT, if the SNOMED CT codes were to be used instead of the local codes in external data exchange, to ensure that the meaning of the patient data remains unchanged.

Migration of a Computerized Anticoagulation Clinic to a Commercially-Developed EHR

Ping Hu, MD, MS1, Mitchell Hedrick2, Aubrey Ramsey, MS2, Christopher Radek2, Keith Huffman2, Adam Miklius2, Adam Wilcox, PhD1
1Intermountain Healthcare, Salt Lake City, Utah; 2Cerner World Headquarters, Kansas City, MO

Abstract: We describe the migration of a computerized anticoagulation clinic application from an internally-developed clinical information system to a commercially-developed EHR. Specific functions are noted, with the corresponding EHR tools that supported them. Initial statistics show successful implementation of the system, which was developed using only existing tools in the commercial EHR.

Introduction: Intermountain Healthcare, long known for its use of clinical decision support (CDS) in an internally-developed electronic health record (EHR), is migrating to Cerner Millennium. An important concern is how advanced CDS can be successfully migrated to a commercially-developed EHR.

Background: In their 2006 landmark review of the impact of health information technology (health IT), Chaudhry et al. identified 4 benchmark institutions, all with internally-developed EHRs, that contributed much of the research on health IT impact. At the same time, they noted a dearth of research on the impact of commercially-developed EHRs. Intermountain recently purchased Cerner EHR, and there is a critical need to migrate these successful CDS applications from an internal, flexible development environment to a more-constrained, commercially-developed system. Recent studies have shown clinicians’ dissatisfaction with commercial EHRs, perhaps due to decreased flexibility. At the same time, internally-developed EHRs are becoming extinct. We describe our migration of a computerized management of an anticoagulation clinic application (CAC) to the Cerner Millennium EHR. This represents an important instance of migrating a successful and complex CDS application to a commercial EHR.

Methods: The CAC application had the following functions: protocol enrollment; INR result follow-up alerting and documentation; warfarin dosage calculation; drug interaction checking; alert routing and acknowledgment; and INR result graphing. The Cerner Millennium components used for each function were: Order Entry (protocol enrollment, drug interaction checking), PowerChart (protocol enrollment, INR result documentation, alert acknowledgment), DiscernDev (INR result follow-up alerting, drug interaction checking, alert routing and acknowledgment), and mPages (warfarin dosage calculation, INR result follow-up and documentation, INR result graphing). A multidisciplinary team, including clinical users and developers, participated in the analysis, design, development and testing of the system in Cerner Millennium.

Results: The application was developed over a 6-month period. There were 217 rules developed, and 11 algorithms. The application was first released on 2/21/2015. Six clinics enrolled 746 patients in the protocol in the first 19 days – these included many patients who had been previously enrolled in the legacy system. There were 1397 alerts generated over the same period. Most of the functions were supported by the standard commercial tools, including the specific data-driven and time-driven rule triggering, alert routing, and alert escalation. Some functions needed more advanced tools within the commercial EHR development environment, but these were supported by the newer mPage development tools. The flexibility of the mPages was critical for the more complex components of the application. No development was needed outside the standard tools or mPages.

Discussion: We were able to successfully migrate a complex CDS application from our internally-developed EHR to a commercially-developed EHR. The original CAC application had been developed and configured over a 10-year period, as guidelines were adjusted and workflows adapted, so it was critical that this optimized functionality was supported. The application is used in over 40 Intermountain clinics, for over 5,000 patients. The existing Cerner development applications were sufficient to support the development, but only with the inclusion of mPages. We expect as mPage functionality advances, and additional sharable health services are developed, even greater flexibility will be supported in Cerner Millennium for complicated CDS.

Deep Sequencing of Phage-Displayed Peptide Libraries Reveals Novel Peptide Motif that Detects Norovirus

Amy M. Hurwitz, B.S., Wanzhi Huang, Ph.D., Robert L. Atmar, M.D.,
Timothy G. Palzkill, Ph.D.
Baylor College of Medicine, Houston, TX

Introduction

Norovirus (NoV) infections are the most common cause of non-bacterial gastroenteritis and lead to about 21 million new cases and cost $2 billion per year in the United States alone. Existing diagnostics have limited feasibility for point-of-care applications, so there is a clear need for more reliable, rapid, & simple-to-use diagnostic tools for detecting NoV. Previous studies have provided proof-of-concept for the use of bacteriophages, or bacteria-infecting viruses, to detect noroviruses. Here, we use deep sequencing and computational analysis to identify a consensus motif within a library of phage-displayed peptides that bind norovirus in vitro.

Methods

In this study, phage display technology was used to screen a naïve M13 phage library displaying over a billion randomized 12-mer peptides for those that bind to NoV virus-like particles, or VLPs (Figure 1). Since NoV strains classified in genogroups GI and GII cause the majority of human outbreaks, we focused on the prototypical Norwalk strain (genotype GI.1) to identify binding reagents. Phage populations were characterized by deep sequencing after three and four rounds of selection for NoV binding, and custom scripts were used to perform computational analysis for the identification of amino acid motifs involved in binding GI.1 VLPs.

![Phage Display Flowchart]

Figure 1. One round of selection involves incubation, washing, elution, and amplification for subsequent rounds.

Results

Deep sequencing of selected phage populations revealed thousands of unique peptides with possible binding to GI.1. The peptides occurring most commonly increased in fractional frequency from round three to four, as did the overall binding affinity of each population for GI.1 VLPs. Computational sequence analysis identified consensus motif, “YRSWXP,” from the phages obtained after round four of selection. Phage ELISAs and solid-phase peptide arrays confirmed the ability of this motif to bind specifically to GI.1 in the context of two 12-mer peptides.

Conclusions

The work reported here provides evidence for the use of phage display technology and deep sequencing for the identification of novel peptides that detect NoV. This method enables rapid identification of lead clones that bind new pathogens and can be further developed to produce optimized protein binders. Further, using phage-displayed peptides directly as detection reagents provides advantages including the ease and low cost of phage propagation and purification, and high avidity provided by the phage structure. Ultimately, this work will lead to the establishment of novel tools for rapid and sensitive diagnosis of NoV infection with specificity for a broad range of clinically relevant NoV strains.

ArticlesAboutMe.org: Disseminating Clinical Trials Results to Patients

Vojtech Huser, MD, PhD1, Anil Yaman MS2, Chunhua Weng PhD2, James J Cimino MD3

1Lister Hill National Center for Biomedical Communications, National Library of Medicine, National Institutes of Health, Bethesda, MD; 2 Columbia University, New York, NY; 3University of Alabama-Birmingham, Birmingham, AL

Introduction
Advances in Web technologies present new opportunities to keep clinical trial participants informed about trial results. Increased interest of participants and trial sponsors in results transparency is reflected in the “Principles for Responsible Data Sharing” issued by the Pharmaceutical Research and Manufacturers of America (PhRMA) in July 2013.1 Prior reports indicate that many human clinical studies terminate due to lack of enrollment.2 Promising to keep participant informed may increase their participation in clinical trials.

Methods
To encourage and reward clinical trial participation by patients, we created a Web service (available at www.ArticlesAboutMe.org) that generates an email every time an article related to a clinical trial is published. The service relies the ClinicalTrials.gov registry (using the NCT identifier associated with the trial) and the PubMed article repository. A subscription to trial email updates is initiated by the trial participant or the trial administrator (after preauthorization). The service performs weekly checks for result publication using two structured trial-article links3 and a free text search for trial NCT.

Results and Discussion
The service was created in October 2014 and piloted until December 2014 using Amazon Web Services cloud infrastructure and the .NET web technology. Since official launch in January 2015, the service has been used for monitoring of over twelve trials. A total of 9 emails with clinical trial results were sent during 11 completed weekly scans (as of March 2015). The service was designed for not only actual trial participants but also general health care consumers that are interested in receiving results of a trial of interest. The majority of clinical trial result publications were detected using free-text PubMed NCT search.

A marketing campaign to selected principal investigators of clinical studies revealed only limited interest to use the service. Targeting trial participants directly at an institutional level or engaging patient advocacy groups may prove more effective. The poster will show results of pending service integration at Columbia University’s Irving Institute for Clinical and Translational Research.

Examining the Role of Bug-tracking Systems in the Maintenance of Electronic Health Records (EHRs)

Salman T. Hussain1, Dustin S. McEvoy2, Thu-Trang T. Hickman, MPH1, Dean F. Sittig, PhD3, Adam Wright, PhD1,2

1Brigham and Women’s Hospital, Boston, MA; 2Partners HealthCare, Wellesley, MA; 3University of Texas at Houston Health Science Center, Houston, TX

Introduction
The maintenance of electronic health records (EHRs) requires the intersection of the healthcare and software engineering industries. Many teams are working on the same project, as software developers, analysts, and physician end-users are all seeking to improve the quality of the EHR. Communication and coordination problems between these groups must be avoided1,2, as they may put patients at risk. For this reason, engineers at Partners Healthcare designed the Team Coordination System (TCS), a computer program with an integrated software team environment enabling different groups to report and track software bugs, application enhancements, changes in specifications, code control, versioning, and releases in the EHR through its dialogue function.

Methods
We conducted a literature review to assess bug-tracking systems used in the monitoring of EHR systems. An initial query of all closed and fixed TCS issues in the Partners’ Longitudinal Medical Record yielded 12,996 issues from 4/10/02 – 3/2/15. We calculated the mean and median resolution times of issues, and also the proportion of issues by their type. We separately reviewed over 1500 TCS issues by querying closed and fixed issues containing CDS-related terms such as “alert” and “reminder”, specifically focusing on how bugs were monitored, to understand the ability of TCS software to help report, identify, and track bug fixes in the EHR.

Results
We observed that the mean resolution time for EHR issues was inversely correlated to their severity. The mean resolution time was lowest for the most severe level 1 issues (11.0 days; median 3 days), though we were surprised that even some of these highest severity issues required up to 144 days to fix. The mean resolution time for level 2 issues was longer (55.3 days; median 10 days) and even longer for level 3 issues (66.3 days; median 23 days). Low severity level 4 issues (89.7 days; median 45 days) and the least severe level 5 operational issues (109.1 days; median 57 days) had the longest resolution times. We also analyzed issues by report type and found that 63.5% of EHR issues in TCS were bugs, 15.0% support issues, 14.4% enhancements, 4.1% usability issues, 1.6% specifications, 0.8% documentation requests, and 0.6% report requests.

Conclusion
While bug-tracking systems are likely used in the design, development, and testing of most EHRs, to our knowledge there are no publications analyzing their use in this context. Retroactively mining bug reports can help us learn how to make systems safer. End users do not currently have access to TCS, as they simply call the help desk and open a ticket to report an issue. Granting end users read/write access to TCS could reduce dependencies between groups, potentially leading to safer and more effective EHRs, not to mention more rapid identification and solution of problems. This analysis highlights that TCS is an instrumental tool to track and fix bugs in EHRs, but that it could be improved with increased usability for physicians.

Examining Cancer Case Reporting Processes and Timeliness: Preliminary Results

Abdulrahman Jabour¹, Brian E. Dixon²,³,⁴, Josette F. Jones¹, David. Haggstrom²,⁴,⁵

¹ Department of BioHealth Informatics, Indiana University School of Informatics and Computing; ² Regenstrief Institute; ³ Department of Epidemiology, Indiana University Fairbanks School of Public Health; ⁴ Indiana University, School of Medicine; ⁵ HSR&D Service, Veterans Health Administration, Department Veterans Affairs

Introduction

Cancer registries collect tumor-related data to identify incidence rates, monitor trends, and support cancer research. One of most common issues with cancer data is timeliness. Delay in reporting is an ongoing, structural issue that is discussed in several U.S. Centers for Disease Control and Prevention (CDC) and Institute of Medicine (IOM) reports. Very few published studies within the United States have examined the reporting timeline within cancer registries.

Often the data collected in local hospitals and other treatment facilities are stored in the hospital’s local registry which are subsequently reported to the state registries. Subsequently, state registries may share data with larger national registries such as Surveillance, Epidemiology, and End Results Program (SEER), North American Association of Central Cancer Registries (NAACCR) and CDC's National Program of Cancer Registries (CDC/NPCR). Delays or bottlenecks in reporting processes at the hospital or state registry level could lead to delays in reporting at the national level. Meeting national standards will have both financial and credibility implications. Therefore, to meet the need for actionable data, both reporting hospitals and the state registry should consider way to accelerate reporting timeliness. Studies in some European countries such as Norway and Sweden show an improvement in timeliness over the years. In this study, we evaluate the timeliness of data at the Indiana State Department of Health’s (ISDH) Cancer Registry from 2001 to 2009. The study will also examine how ISDH Cancer Registry data compares to other, national registries’ standards.

Method

Reporting timeliness was calculated by measuring the number of days from the date of diagnosis to the date when data become available for reporting at the state registry. The study includes breast, colorectal, and lung cancer cases in the state of Indiana from 2001 to 2009. Calculations include the mean, median, and the percentage of records that meet the predefined measures for reporting performance. Predefined measures was drawn from the following national standards for cancer registries; SEER, NAACCR, and, CDC/NPCR. Delays in reporting were stratified by the type of cancer and by year to assess the degree of consistency in reporting speed.

Preliminary Result

A total of 66,409 cases were examined. Depending on year of diagnosis only 3.9% to 37.2% of cases were reported within 6 months from the date of diagnosis. Between 94.8% and 98.8% of cases were reported within 2 years. The CDC/NPCR requires 95% or more of the cases to be reported within 24 months from the date of diagnosis, and SEER requires 98% or more to be reported within 22 months. NAACCR requires 90% or more for silver, and 95% or more for gold within 23 months. Comparing these standards, the ISDH Cancer Registry met the CDC/NPCR and NAACCR for the entire 9 years, but it only meet the SEER standard in 2002, although the ISDH tumor registry does not participate in the SEER program. The result also shows that reporting timeframes did not vary meaningfully based on cancer type.

Over time, we observed a large variation in the mean reporting time across time that ranged from 426 days in 2003 to 252 days in 2009. Following an initial sharp (46%) increase in reporting time from 2002 to 2003, we observed a gradual decline in reporting times through 2009. The longer reporting time observed in 2003 was concurrent with changes in the reporting requirements such as the implementation of the Facility Oncology Registry Data Standards (FORDS) coding standard.
Representation of Clinical Practice Guideline Data Elements Using the Health Level Seven Fast Healthcare Interoperability Resources (FHIR) Standard as a Proposed Data Formalism for the Arden Syntax

Robert A. Jenders, MD, MS, FACP, FACMI
Charles Drew University & University of California, Los Angeles, CA

Abstract
Context: Arden Syntax can adequately represent clinical practice guidelines (CPGs) in clinical decision support systems but lacks a standard data formalism. Objective: Assess Health Level Seven’s Fast Healthcare Interoperability Resources standard (FHIR) representation of CPG data. Method: 16 CPGs containing 806 data elements were tabulated. Result: FHIR can represent all but 2.7% of these data elements. Conclusion: FHIR adequately represents data elements in CPGs. Incorporation of FHIR in Arden Syntax would facilitate representation of CPGs.

Introduction
Arden Syntax is an American National Standards Institute (ANSI) standard supervised by Health Level Seven (HL7) for representation of executable medical knowledge with the goal of facilitating its sharing among clinical decision support systems (CDSS). Key to minimizing site-specific changes when sharing knowledge is the standardization of database linkages, which in turn requires a standard data model, vocabularies and query syntax that are not present in Arden1. The HL7 FHIR draft standard for trial use (DSTU) Release 1 is a new framework that allows references to data to be represented in XML and bound to terminologies in modular components known as “resources.” For example, concepts such as “patient,” “medication” and “observation” are key FHIR resources, each with structured attributes that may be other resources. The American College of Physicians (ACP) is a large professional organization of internal medicine specialists in the USA that publishes evidence-based clinical practice guidelines (CPGs) pertinent to medical practice that are representative of CPGs generally because of ACP’s size and clinical focus. The present work was undertaken to assess FHIR’s utility in representing data elements in ACP CPGs that in turn might be represented in a CDSS using Arden Syntax in order to assess FHIR’s utility as a standard data formalism for the Arden Syntax.

Methods
The data elements in the current ACP CPG library were identified and tabulated using Microsoft Excel. Each then was assessed to ascertain whether it could be specifically represented using FHIR DSTU Release 1.

Results
Three hundred sixty-eight distinct data elements were identified among 806 total elements in the CPGs that contained 121 recommendation statements that could be implemented in a CDSS. Nearly all of these elements could be classified as observations, procedures, medications, diagnoses and diagnostic reports and could be represented in FHIR. Of the 368 distinct data elements, 11 (3%) corresponding to 22 (2.7%) elements in the collection of 806 total elements could not be directly represented. These included elements such as “preference” and inference data such as “ease of use.”

Conclusions
FHIR is adequate to represent the data elements found in a robust corpus of CPGs that in turn would be a typical knowledge base in a CDSS. Consideration should be given for use of FHIR to represent data elements in a standard way in the Arden Syntax in order to facilitate knowledge sharing.

An Interactive System for Comprehensive Geriatric Telerehabilitation

In cheol Jeong, PhD¹, Joseph Finkelstein, MD, PhD¹
¹Chronic Disease Informatics Program, Johns Hopkins University, Baltimore, MD

Introduction

High acceptance of home-based telecare applications by patients with various chronic health conditions has been widely demonstrated. In older patients, particular interest has been expressed in home-based telerehabilitation supporting regular exercise. To address this interest, we developed an interactive aerobic and strength exercise system based on Home Automated Telemanagement (HAT) model. In this article, we present the system design and introduce the system performance.

System Design

The design of the home-based telerehabilitation system supports flexible exercise prescription and remote control of exercise settings by a comprehensive rehabilitation team, automated exercise records, real-time monitoring of patient progress towards recommended patient-specific exercise goals, and generation of exercise safety alarm. The home station, such as PC, tablet or smart phone, generates a detailed exercise log which can be communicated to the patient rehabilitation team. This allows the patient providers determine which exercise settings are more challenging to the patient. There are also general exercise safety tips as well as specific tips for each exercise designed to minimize the risk of injury during exercise. A touch screen dashboard is used for the patient interface to start, stop or skip exercise by the patient preferences and to receive feedback on the exercise status during patient exercise. The dashboard has been optimized for individuals with possible limitations in vision, locomotion, and cognition. The patient unit includes an arm/leg biking device (SF-B02 Motorized Mini Bike, Sunny Health Fitness, USA) and a resistance chair with attached elastic bands (CFC-100B-S, VQ ActionCare, LLC, USA) and SpO2 monitor that sends heart rate (HR) and SpO2 level data to the home station. The system design is shown in Figure 1.

System Performance

The system can acquire all exercise and physiological information throughout execution of prescribed exercises. During the aerobic exercise, current and target information such as speed, distance, exercise time, calories burnt, HR and SpO2 level are presented in a user-friendly trending format on the exercise dashboard in a real-time mode. During the resistance exercise, type, direction, target, number of repetitions, percentage of exercise similarity, HR SpO2 levels and whether the user reaches the target goals are presented. The entire log of the performed exercise is directly sent to the HAT server. When any exercise parameter exceeds the pre-setup alarm thresholds, the patient is notified and the program ends automatically for the entire exercise session. Additionally, the aerobic exercise can provide alternative exercise modes including patient-driven mode for fit patients and assisted motor-driven mode for frail patients.

Conclusion

Comprehensive home-based geriatric telerehabilitation system has significant potential in providing aerobic and strengthening exercise support and performance feedback, communicating results to a clinical rehabilitation team, and supporting safe and efficient exercise at senior patient homes.

Harmonization of Quality Data Model with HL7 FHIR to Support EHR-driven Phenotype Authoring and Execution: A Pilot Study

Guoqian Jiang¹, Harold R. Solbrig¹, Richard Kiefer¹, Luke V. Rasmussen², Huan Mo³, Jennifer A. Pacheco², Enid Montague², Jie Xu², Peter Speltz³, William K. Thompson², Joshua C. Denny³, Christopher G. Chute⁴, Jyotishman Pathak¹

Abstract
The objective of this pilot study is to describe a crowdsourcing effort in harmonizing high-level data elements between Quality Data Model (QDM) and HL7 Fast Healthcare Interoperability Resources (FHIR) to support electronic health records (EHR)-driven phenotype authoring and execution. In total, 206 mapping pairs between the two models were identified, with a Fleiss's kappa statistics (k=0.24) calculated for inter-rater agreement. We discuss challenging issues of the mappings.

Introduction
In previous studies, we developed a metadata repository and its services for data elements derived from Quality Data Model (QDM) and HL7 Fast Healthcare Interoperability Resources (FHIR) to support electronic health records (EHR)-driven phenotype authoring and execution (1-2). In the present study, we describe a crowdsourcing effort in harmonization of high-level data elements between the two models. The purpose of the harmonization is to understand the domain coverage of the two models and to establish the degree of interoperability between QDM-based phenotype algorithms and patient data populated with FHIR models.

Methods
We extracted a collection of high-level data elements with their textual definitions from both QDM and HL7 FHIR using our metadata repository services (http://projectphema.org). We designed a mapping application using an Excel spreadsheet. We created five worksheets: instructions, mappings, QDM data elements with definitions, FHIR data elements with definitions, and SKOS mapping properties with definitions. One-to-many mappings are allowed by the spreadsheet application. We used five SKOS mapping properties (exactMatch, closeMatch, broadMatch, narrowMatch and relatedMatch) as the mapping types. We asked the project team members to complete the mappings individually and Fleiss' kappa statistics was calculated to assess inter-rater agreement.

Results and Discussions
In total, 94 data elements from QDM (consisting of 18 QDM Categories and 76 QDM Datatypes) and 98 data elements from FHIR (all FHIR Resources) were extracted for mappings. We received the responses from 7 team members and 206 mapping pairs were created. All QDM data elements had at least one mapping suggested whereas 65 FHIR data elements did not have any mappings. Only fair agreement (kappa = 0.24) was achieved. The QDM categories Communication, Condition/Diagnosis/Problem and Encounter were in relatively high agreement. The textual definitions of the data elements, along with multiple factors (e.g., attributes associated with each type, ambiguity in naming within two models), are important for creating correct mappings. In summary, the pilot study provides valuable insight into the challenging issues for a community-based harmonization of QDM and HL7 FHIR. In the future, we plan to extend the harmonization effort in collaboration with broader clinical research communities, aiming at producing a collection of complete and high-quality mappings.

Physician Participation in Meaningful Use and Rehospitalization of the Dually-Eligible

Hye-Young Jung, PhD1, Mark Aaron Unruh, PhD1, Joshua R. Vest, PhD1, Lawrence P. Casalino, MD, PhD1, and Rainu Kaushal, MD, MPH1,2,3,4, for the HITEC Investigators

Abstract: Dual-eligibles have higher rates of rehospitalization compared to the broader Medicare population. Outpatient physicians’ use of interoperable electronic health records may reduce readmission rates. We compared the odds of rehospitalization pre/post Meaningful Use for dual-eligibles attributed to physicians who participated in the program with dual-eligibles attributed to matched control physicians. Relative to the control group, physician participation in Meaningful Use was associated with 6% lower odds of rehospitalization (Odds Ratio: 0.94, 95% confidence interval: 0.90-0.98).

Introduction:
Compared to the broader Medicare population, dual-eligibles participating in both Medicare and Medicaid have substantially higher rates of rehospitalization.[1] Readmission has been associated with gaps in care following hospital discharge,[2] a common problem for dual-eligibles. Physician use of interoperable electronic health records (EHRs) may reduce rates of rehospitalization of dual-eligibles. Use of highly functional EHRs within a practice can help with outpatient coordination, and interoperable exchange of information with hospitals can help with transitions of care to and from the hospital. The Meaningful Use program has made nearly $30 billion available to encourage provider adoption and use of interoperable EHRs.[3] The objective of this study was to evaluate the impact of outpatient physicians’ participation in Meaningful Use on rehospitalization of dual-eligibles.

Methods:
Multiple sources were used to construct our analytic file. Medicare enrollment records, carrier files and MedPAR files were used to derive patient demographics, diagnosis and procedure codes, hospital length of stay, and use of an intensive care unit. Physician and practice characteristics were obtained from the SK&A Physician Database. Meaningful Use participation was identified through dates of successful attestation found in program payment records. The study population included 316,468 dual-eligibles in the State of New York hospitalized over the period 2010-2012. Each patient was attributed to a physician with a plurality of outpatient evaluation and management claims. We used a quasi-experimental design, utilizing the differential timing of physician participation in Meaningful Use to estimate the program’s effect on rehospitalization. Our outcome variable was a binary measure of all-cause 30-day readmission. The determinant of interest was a binary indicator of Meaningful Use participation. The intervention group included patients attributed to physicians who participated in Meaningful Use during the study period. Comparison groups included patients attributed to physicians who joined Meaningful Use after the study period, but who used paper records or EHRs without Meaningful Use participation during the study period. Estimates were derived with a multivariable logistic regression model with hospital and year fixed effects that controlled for temporal trends and unobserved cross-sectional heterogeneity between hospitals.

Results:
Physician participation in Meaningful Use was associated with 6% lower odds (Odds Ratio: 0.94, 95% confidence interval: 0.90 to 0.98) of rehospitalization among attributed dual-eligibles compared to patients attributed to physicians using paper records or EHRs without Meaningful Use participation.

Discussion:
Our findings suggest that investments in interoperable EHRs made through Meaningful Use may improve care for dual-eligibles through reductions in rehospitalization. Our study represents the first evidence of the impact of physician participation in the program on the quality and efficiency of care among the dually-eligible. Future study is warranted to examine whether further reductions in readmission rates will occur as physicians gain more experience with EHRs and as interoperable exchange of information with hospitals increases. It will also be important to determine whether a similar reduction in readmissions occurs for patients of physicians who join the Meaningful Use program in later years.

Natural Language Processing facilitates delivery of individualized recommendations at the point of care

Mayo Clinic, Rochester, MN, USA

Introduction
Mayo Clinic has made significant strides in developing knowledge assets and the tools to manage them. To fully realize the value of these assets, it is pertinent not only to embed the knowledge into the clinical workflow but also contextualize the knowledge to individual patients\(^1\). To ensure the delivery of standard guidelines, we have created care process models (CPMs) for various conditions. However, individualized patient care according to CPMs requires the review and obtainment of relevant clinical information from both structured data fields and unstructured sources of information\(^2\) such as clinical notes, lab reports, etc. While information in structured fields is highly useful, the integrated information from both structured and unstructured repositories at various time points provides comprehensive views during personalized decision-making. Here, we discuss a multi-stage iterative development of an NLP system that extracts data elements needed for automating care process models for hyperlipidemia, atrial fibrillation and heart failure. We also investigated how NLP helps to fill the information gap that exists in structured data sources and empowers clinical decision-making at the point of care.

Methods
As the first step, we developed a gold standard corpus based on the guidelines (Supplementary File1\(^3\)). The corpus was identified through stratified sampling from a retrospective cohort for the data elements pertaining to the three care process models (CPMs) namely Atrial Fibrillation, Heart Failure and Hyperlipidemia. Based on the gold-standard annotations from clinical notes, we developed regular expressions using MedTagger\(^4\) to extract (See Supplementary File2\(^5\)) the data elements from selected sections in clinical notes. The choice of a rule-based approach stems from the overall goal of the project to achieve a very high precision (~100%), at the cost of lower recall. We iteratively refined the rules developed to extract data elements based on the analysis carried out after each run.

Results
The system was evaluated against the gold standard annotated data set in an iterative manner. The system achieved an overall F-Measure of 92.61% on blind data set. We also conducted a pilot evaluation regarding the impact of NLP on individualized care recommendations made on 14,000 patients. The NLP system decisions when combined with the information in structured data made significant differences to the care recommendations to 1,730 patients\(^6\). The NLP system reversed the care recommendations for 155 patients, while it suggested alternative care recommendations to 1, 885 patients. We will soon realize the robustness of the NLP recommendations as the physicians are reviewing the care recommendations made by MEA in the pilot study.

Conclusions and Future work
We have successfully integrated an NLP system into an EMR agnostic care recommendation solution system, MayoExpertAdvisor. The adopted batch-wise iterative system development has yielded a robust NLP system with acceptable performance.

Selection of a Database Engine for the National Master Patient Index of Malawi

Chimwemwe Kachaje1, Blessings Mhango1, Mwatha Bwanali1, Soyapi Mumba2, Jeremy U. Espino3 MS MD, Gerald P. Douglas3 PhD
1Baobab Health Trust, Lilongwe, Malawi, Africa
2Center for Health Informatics for the Underserved, Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA

Abstract

Objective: Select a database engine for the Malawi national master patient index that supports multiple synchronized databases over an unstable network. Methods: We reviewed the capabilities of the database engines that fulfill the objective using multi-master replication. We tested the selected database using a 22 test cases and simulated dataset of 72.9 million records. Results: We chose CouchDB as our database solution and it passed our test cases. Conclusions: CouchDB can provide an infrastructure for a distributed, scalable and reliable master patient index.

Introduction

On March 19th 2001, we deployed the first Baobab Health Electronic Medical Record (EMR) system at Kamuzu Central Hospital in Lilongwe, Malawi.1 In 2009, the EMR was adopted nationally for the HIV clinics at district and central hospitals of Malawi. As usage grew, users of the system wanted consistent and seamless access to patient demographics across the district and central hospitals.2 To fulfill this need we needed a master patient index (MPI).

Initially, we rolled out an MPI solution based on a centralized MySQL database and a data synchronization solution that we wrote ourselves, the Demographic Data Exchange (DDE). As the number of sites using the DDE grew to 29 sites, it became apparent the system could not reliably synchronize data. The DDE suffered from denial of service when multiple clients tried to synchronize simultaneously. When there were extended network outages, data synchronization among the sites did not finish and could not recover. The DDE issued duplicate IDs because it did not handle concurrent operations. Over time, data from one site was inconsistent with the data at another site.

We recognized that the challenges we encountered with the first version of the DDE were because of the complexity of implementing a multi-master replicated database cluster. Multi-master replication is a method of database replication which allows data to be stored by a group of computers, and updated by any member of the group.3

Methods

We examined the characteristics of existing open source databases that support multi-master replication—CouchDB, MySQL, and PostgreSQL. We wrote and executed a test plan for testing the synchronization capabilities of the selected database.

Results

We selected CouchDB as our database solution. Our research revealed that although MySQL supports multi-master replication it requires a stable communications network to operate well.4 Multi-master replication for PostgreSQL would not appear until PostgreSQL version 9.4.3

We wrote a set of 22 test cases and generated a simulated data set of 72.9 million records (the maximum number of patients we could represent using our seven character base 30 patient id). We executed the test cases in our laboratory using the data set—evaluating consistency of the data over simulated network conditions. An example test case was “Test #16 – Synchronization of IDs and Benchmarking of Cellular Connection; Procedure: Allocate 10 IDs on node 1. Perform synchronization to nodes 2-5. Record synchronization time; Test Criteria: Synchronization time recorded. 10 NPIDs are present/updated on all proxies and master.”

Conclusion

CouchDB has the potential to provide an ideal infrastructure for a national master patient index. Such a system would permit patients to use a single ID for all facilities, enhance monitoring and evaluation statistics and in the future, share abstracts of medical records across sites.
Implementing an EMR-based “No Opiate” Policy In The Emergency Department

Zachary P. Kahler, MD¹, Paul I. Musey, MD¹, John T. Finnell, MD MS², Annelyssa Johnson, MD¹, Christi Saupp, RN¹, Christian Strachan, MD¹, Charles Shufflebarger, MD¹
¹Indiana University, Indianapolis, IN, USA; ²Regenstrief Institute, Indianapolis, IN, USA

Introduction
Opiate-seeking behavior is a major problem in U.S. emergency departments (ED) and leads to recidivism and ED misuse¹,². Our department has created an EMR-based opiate “warning flag” to help transition frequent opiate-seeking patients away from the ED and into an outpatient chronic pain program.

Outcomes
The primary objective is to evaluate the effect of the EMR-based intervention on patient visits to the ED. Secondary outcomes include number of lab draws, ECGs, X-rays, CTs, and days spent in the hospital for the year pre- and post-enrollment in the program.

Methods
The emergency department has identified approximately 280 patients to date who frequently visit the ED requesting opiate pain medications. A panel of social workers, case managers, and ED administrators reviewed their charts. Upon consensus agreement, the patients were informed that (1) they would undergo referral to an outpatient chronic pain management clinic; (2) they would no longer receive opiate prescriptions from the ED for chronic painful conditions; and (3) an EMR-based notification would inform all ED providers of the patient’s ED pain program referral status. A case management note type entitled “Chronic Pain Program” fires a discern order, activating three Cerner rules. When the patient presents to the ED, the first rule notifies anyone attempting to access the chart of the patient’s referral status to the chronic pain program. To access the chart, the provider must dismiss the notification. A second rule applies a stop sign icon to the tracking board as a visual reminder, and is triggered by the same criteria. The third rule triggers if a provider attempts to order opiates on a patient referred to the program.

Data Analysis
Any patients referred to the program for less than one year were excluded from data analysis to ensure all patients had one year of data pre- and post-enrollment. Wilcoxon signed-rank test was performed for paired medians of non-normal data. Data analysis was performed with RStudio software version 0.98.1073.

Results
243 patients met inclusion criteria and had been referred for at least one year. Median ED visits decreased from 14 per year to 4 (p<0.001). Median CT scans decreased from 2 to 0 (p<0.001), with the outlier patient dropping from 32 to 16 scans. Median X-rays decreased from 5 to 1 (p<0.001), labs performed from 47 to 13 (p<0.001), and ECG’s from 4 to 2 (p<0.001), with the outlier ECG patient decreasing from 158 ECG’s to 49 after enrollment.

Conclusion
This intervention decreased both ED visits and overtesting for opiate seeking patients after they were informed that the ED would no longer provide opiate prescriptions for chronic painful conditions. A major component of the success of this policy is the EMR-based reminders to providers. One downside to this method of implementation is the potential slowdown from too many active rules in the system. Another is provider alert fatigue as ours is not the only discern alert that fires on opening charts.

Characteristics of Older Adults’ Adherence of a Wearable Fall Detection Device
Youjeong Kang¹, PhD, Shomir Chaudhuri², PhD, Hilaire J. Thompson¹,², PhD, George Demiris¹,² PhD
¹School of Nursing, University of Washington, Seattle, WA
²School of Medicine, University of Washington, Seattle, WA

Introduction: Falls are the leading cause of fractures and other serious medical conditions related to aging.¹ One in three older adults in the United States experiences falls.² In many cases older adults who have experienced a fall remain on the floor undetected for longer periods of time, exacerbating the negative effects of the fall.³ One informatics strategy to detect falls is the use of sensor technology, such as wearable sensor devices.³ However, little is known about characteristics of older adults who use a fall detection device compared to those who do not.

Objectives: To describe the characteristics of older adults involved in a study exploring the use of wearable fall detection technology as it relates to adherence of wearing the device.

Methods: This is a secondary analysis of a study that explored the use of a wearable fall detection device with a GPS system and automatically detected falls among community dwelling older adults. A total of 18 participants were recruited, and asked to wear the device continuously for a period of four months. As part of their involvement, they were interviewed at baseline, at two and at four months, and were asked to fill out a fall calendar. Additionally, the device provided an online daily log that indicated whether the device had been charged that day and removed from the charger or not. Adherence was measured based on the use of the charger for each day in the study. If the device was removed for more than 20 minutes in a day, it was considered that the participant had used the device. For the purpose of this study, the cutoff percent for adherence was 85% (i.e., participants wore the device on at least 85% of the study days). The cutoff of 85% was determined based on the mean of participants’ wearing time. Participants were classified into the adherent group (≥ 85%) and the non-adherent group (<85%) based on log data. We extracted baseline interview notes. During the baseline interview, participants were asked to state their comfort level with four specific activities: a) using the stairs, b) getting groceries, c) going for walks and d) doing chores around the apartment. Comfort was categorized into two levels (i.e., no, and yes with assistance or yes). We also assessed if subjects wore a personal fall detection device prior to study entry. We utilized the baseline interview notes to identify concerns about the use of a fall detection device, and performed crosstabulation using SPSS version 22 to describe percentages of the comfort level of activities.

Results: All participants had a prior history of falls. Ten participants (56%) were adherent to using a wearable fall detection device. The mean age of adherent participants was 85 years (SD: 9.0), while the mean age of non-adherent individuals was 88 (SD: 5.0). According to baseline interviews, adherent participants were concerned about forgetting to wear the device, while non-adherent participants were concerned about forgetting to charge a device. Fifty percent of those in both the adherent (n=5) and non-adherent (n=4) groups used a fall detection device prior to enrolling in the study. Those in the adherent group reported more comfort among the four activities of daily living, than participants in the non-adherent group [using the stairs (83% vs. 17%); getting groceries (71% vs 29%); going for walks (66% vs 34%); doing chores around their apartments (53% vs 47%)].

Conclusions: Our findings suggest that older adults who are active both inside and outside the home based on responses to the comfort level questions are appropriate target users of a wearable fall detection device with a GPS function. As such devices will only work in those who wear them, future research using a larger sample and a longer study period is warranted to identify factors that contribute to adherence, to increase their use and usefulness.

Question Types in Online Health Communities
Shaheen Kanthawala¹, MA; Courtland VanDam¹, MA; Barbara Given¹, PhD, RN, FAAN; Joyce Chai¹, PhD; Amber Vermeeesch²; PhD, MSN, FNP-C, RN; Marianne Huebner¹, PhD; John Crowley³, MBA; Jina Huh¹, PhD
¹Michigan State University, East Lansing MI; ²School of Nursing, University of Portland, Portland, OR; ³Alliance Health, Salt Lake City, UT

Introduction
Online health communities and discussion boards can benefit from health experts. However, because of the large scale at which online conversations occur, health experts can find it challenging to moderate posts effectively. Automated identification of questions requiring moderation can streamline this process. To support this automation, we need an annotation codebook, which can help generate training data for the classification of question types.

Among many prior works examining taxonomy of questions ¹ ² ³, Rothwell’s classification of questions⁴ most appropriately addressed the needs of patients’ questions in online health communities. Rothwell categorized questions as (1) fact (asks of something is true and to what extent), (2) value (asks for an evaluation of an idea, object, event or person, which we interpreted as evaluations based on personal experience), or (3) policy (asks if a specific course of action should be undertaken to solve a problem). We built on Rothwell’s model and added (4) social vs. non-social, (5) clinical vs. non-clinical, and (6) question vs. non-questions to address unrelated posts in our dataset (e.g., posts without questions, discussing weekend plans).

Methods
We first examined: (1) What types of questions, based on Rothwell’s model, exist in online health communities? and (2) which question types among them need clinical expertise? Answers to these questions will inform building training dataset for creating automated classification of patient questions in online health communities. We downloaded all questions posted on an online diabetes community from 2007-2014. We selected shorter posts to begin our study with manageable question length: all posts under 100 characters (n=563) and half of the posts with 100-200 characters (n=500). One coder then manually labeled these questions with our classification scheme built on Rothwell’s question types, iteratively checking agreement with another coder.

Results and Discussion
The two shorter question length groups showed similar percentage breakdowns among question types. The types of questions based on Rothwell’s classification as well as those needing clinical attention or not broken down into pie charts in Figure 1. We plan to further examine longer questions to understand whether composition of question types will continue to be similar for longer posts. Our work presented in this poster contributes to developing training data for automatically detecting questions needing health experts in online health communities.

aceso (After Cancer Education and Support Operations): a clinical decision support system approach for engaging breast cancer survivors

Akshat Kapoor, M.S.1, Priya Nambisan, Ph.D.1
1University of Wisconsin-Milwaukee, Milwaukee, WI, USA

Introduction
Most modern electronic medical record (EMR) systems today incorporate a clinical decision support system (CDSS) which provides relevant and timely prompts to the physician, based on a set of pre-compiled rules. This technology provides an interactive medium to aid the physician in making clinical decisions. This approach has until now, never been used in consumer health applications intended for patient use. By incorporating this approach in a specialized system (aceso) that supports breast cancer survivors, we explore an alternative means to achieving patient engagement by providing a more interactive online user experience. The system described below is fully developed and is at the beginning stages of testing with end users.

Purpose
The system aims to provide a more, interactive and engaging alternative to patient portals by employing a decision support system approach, in order to support breast cancer survivors.

Problem addressed
Most patient portals in their current state, are a missed opportunity due to their nature of being very generic and aim to serve the entire patient population using a one size fits all approach. There are however special patient groups that could greatly benefit from portals that provide specialized functions. Breast cancer survivors can expect to experience several treatment-related side effects, several weeks after treatment. By employing a clinical decision support systems approach and incorporating feedback in the form of warnings, alerts and reminders for the patient, the system explores making the patient experience more interactive for this group of patients.

System Overview
aceso is an online breast cancer survivorship tool that may be accessed from a variety of web-enabled devices using a simple web browser application. By providing relevant, real time feedback to the patient in the form of warnings, alerts and reminders, aceso actively interacts with the patient. These warnings, alerts and reminders are based on a set of pre-compiled rules, based on breast cancer survivorship guidelines1. Each rule is constructed on the basis of three components: condition (various treatment related side-effects), context (breast cancer related medical history) and action (generation of an alert message or reminder). A benefit of using a set of pre-defined rules in this context is that they are relatively easy to modify and maintain to keep up with changes in guidelines.

Current system state and evaluation
The system has completed design, development and testing phases and IRB approval has been obtained for end user evaluation. Approximately 120 breast cancer survivors are currently being recruited to test and evaluate the system over a period of two months. The system will be evaluated on the basis of its perceived impact on various breast cancer related quality of life indicators, patient-provider communication and patient engagement.

Conclusion
This system has the potential to demonstrate that more personalized and specialized online tools can play a key role in filling the existing gap in the consumer health domain. As patient engagement continues to become a vital component of Meaningful Use Stage 2, healthcare providers should look at alternative means to more effectively engage patients in taking an active role in managing their health in a more interactive manner.

OpenMRS and FHIR: The Promise of a Domain Independent API for serving Healthcare Needs Across Underserved Settings

Suranga N. Kasthuriratne, BEng¹, Harsha Kumara, BSc², Burke Mamlin, MD¹,4, Paul G. Biondich, MD, MS³,4
¹School of Informatics and Computing, Indiana University – Purdue University, Indianapolis, IN, USA; ²WSO2 Inc., 20 Palm Grove, Colombo, Sri Lanka; ³Indiana University, Indianapolis, IN, USA; ⁴Regenstrief Institute Inc., Indianapolis, IN, USA

Introduction

The implementation of Electronic Medical Record (EMR) systems across underserved settings is impaired by the lack of technical resources to manage these systems. The enforcement of system specific Application Programming Interfaces (API’s) hinders EMR adoption as they require developers to familiarize themselves with system specific restraints. Another limitation of system specific APIs are that they may not be aligned with any specific interoperability standard, and is challenging to use in support of interoperability between multiple healthcare applications. Given the critical nature of EMR systems there is an acute need to enforce the proper use of standards on implementers of healthcare applications. As an Open Source EMR system that is widely used across underserved settings, OpenMRS has actively felt the need to reduce the learning curve involved with implementing our platform, and to enable standardized data exchange between healthcare applications. We sought to address these limitations by developing a system independent API that could easily be leveraged to promote interoperability. We also sought to design a best approach for a system independent API to work coherently across different versions of a healthcare standard and OpenMRS data model.

Methods

The Fast Health Interoperable Resources (FHIR) [1] standard is a next generation standards framework introduced in response to limitations in HL7 V2 and V3. FHIR combines the best features of HL7’s V2, V3 and Clinical Document Architecture (CDA) messaging standards while leveraging XML, JSON, HTTP and Open Authorization (OAuth). Unlike HL7 V2 and V3, FHIR promotes the use of resources that makes it easier to map them to existing clinical objects within the OpenMRS data model. Upgrading our API to communicate using FHIR would enforce proper standardization of clinical data and reduce the learning curve necessary to use OpenMRS. We sought to develop a FHIR based API that would act as an additional layer above the legacy OpenMRS API, and serve FHIR based resources to users. In addition, we sought to utilize a strategy pattern based approach that allowed the FHIR API to work with different versions of the OpenMRS data model.

Results

We built an add-on FHIR module that would be installed atop the traditional OpenMRS API, and serve as an optional FHIR API to serve FHIR resources to third party users. The initial development phase completed support to export OpenMRS data using a subset of FHIR resources. We also supported a subset of FHIR search parameters based on OpenMRS specific needs. The completed module supports the latest FHIR Draft Specification for Trial Use (DSTU2), and leverages a strategy pattern based handler approach to manage different versions of data objects. Currently, further development work is underway to support the creation and updating OpenMRS data based on FHIR requests. This, as well as additional work to support OAuth security for OpenMRS is expected to be completed by October 2015.

Discussion

By implementing a FHIR based API we resolved the need for implementers to ‘learn’ OpenMRS. Instead of learning a system specific API developers need only learn FHIR, which is appropriate given that it is a standard that is being widely adopted by many EMR systems. We perceive that a standardized API will also enable better interoperability support and help address the challenge of linking together health data fragmented across different EMR systems. During the initial phase, both the FHIR API and the system specific OpenMRS API will be available to consumers of OpenMRS. Following a suitable grace period for users to acclimate themselves with FHIR we plan to deprecate the legacy system specific API in favor of the FHIR based API. We envision that the FHIR API will become the preferred approach for communicating with the OpenMRS API, and be used to serve both internal API calls as well as external requests.

Design and Implementation of a Relevant Data Report Tool for Patients Presenting to the Emergency Department with Chest Pain

Chris Katsura, MD, Lynnell McCullough, MD, Frank C. Day, MD MPH.
David Geffen School of Medicine at UCLA, Los Angeles, CA

Abstract
Few clinical decision support tools exist to extract in real-time the pertinent portions of a patient’s voluminous medical record. A patient who presents with chest pain (for example) may or may not have relevant information documented in multiple disparate locations within an electronic health record (EHR). We will create a summary tool that automatically gathers and displays relevant data in a full-report format. We intend to apply this model to other chief complaints and hospital departments.

Introduction
Healthcare providers today are often inundated with massive amounts of stored electronic data. This can be particularly problematic in the Emergency Department, where clinicians constantly face constraints on the amount of time that can be allocated to combing through electronic charts comprised of terabytes of data, potentially missing crucial test results. At our institution, there is no current automated method to compile the data that is relevant to a patient’s chief complaint. Relevant tests are often entered in generically as progress notes or titled under other categories, depending on the generating service. Chest pain is a frequent complaint that comprises five percent of all ED visits, and the patient usually presents with multiple medical conditions and extensive medical records. The likelihood that this complaint represents an acutely life-threatening process may be informed by the results of a wide variety of imaging, procedural, and specialist assessment resources. We hypothesize that inserting a relevant data report into physicians’ standard EHR workflow will result in increased awareness of and review of relevant data sources, and that patients may receive more appropriate workups and dispositions. For practical purposes, we decided to apply our efforts for the initial prototype to patients presenting to the Emergency Department complaining of chest pain, with the ultimate goal of expanding this concept to other common chief complaints (such as abdominal pain, shortness of breath, etc.).

Methods
A multidisciplinary task force comprised of physicians, EHR vendor technical support, and EHR system builders was formed to develop and evaluate a new clinical decision support tool, in the form of an expandable multi-layered side bar that automatically gathers relevant patient data from multiple sources and displays it all in one convenient location. Relevant data can then be easily accessed as a full-report. For patients presenting to the Emergency Department primarily for chest pain, the most recent important cardiac tests (stress, echo, cardiac catheterization, etc.) and cardiology notes are readily accessible at the click of a button. The patient’s medical record will be filtered using categories such as date, exam type, category type, and service to obtain the specific reports. Smart searches for exact terms and synonyms through the physical narrative body of the note will locate inconsistently titled reports and extract pertinent information. In addition, the complete set of all data sources will be validated with colleagues from cardiology and radiology, to ensure that all relevant notes and tests are captured. To determine the effect of the relevant data report tool, we will explore various methods to measure physician work flow, efficiency, door to disposition time, observation admissions, and appropriateness of patient testing.

Conclusion
As a result, the clinician can more quickly and accurately risk stratify a patient complaining of chest pain. Furthermore, this tool will streamline overall workflow, boost efficiency, improve coordination of patient care, and minimize unnecessary cardiac testing. In the future, this prototype model will be implemented across other chief complaints and other medical specialties as a clinical decision support and risk stratification tool.
An Easy-to-Use Clinical Text De-identification Tool for Clinical Scientists: NLM Scrubber

Mehmet Kayaalp, MD, PhD, Allen C. Browne, MS, Zeyno A. Dodd, Ph.D., Pamela Sagan, RN, Clement J. McDonald, MD
Lister Hill National Center for Biomedical Communications, U.S. National Library of Medicine, National Institutes of Health, Bethesda, MD

Abstract
Health Insurance Portability and Accountability Act (HIPAA) requires that clinical documents be stripped of personally identifying information prior to their secondary use for clinical research. We have been studying clinical text de-identification for more than a decade and developing NLM Scrubber—it is a tool for every clinical scientist who conducts retrospective research using clinical reports. Although we continuously improve and add new functionalities to it, it is very simple to install and use.

1. Introduction
The Privacy Rule of Health Insurance Portability and Accountability Act (HIPAA) requires that clinical documents be stripped of personally identifying information before they can be released to researchers and others; however, manual clinical text de-identification is an arduous task. Furthermore, human annotators alone are usually not as accurate as automatic clinical text de-identification systems. Even though no automatic de-identifier is perfect, they can quickly produce de-identified text, which can then be easily reviewed and verified by the data providers for their de-identification accuracy. If and when the de-identified text needs revisions, the necessary editing is usually minimal.

2. NLM Scrubber
The major downside of commercial de-identifiers is obviously their cost, which many clinical scientists may be unable to afford. Most other de-identifiers found in the literature have been developed for research purposes only and are not available. Besides their no cost to the user, the major advantage of the few freely available de-identifiers is that they can be easily tested, evaluated and verified by independent third parties. The freely available de-identifiers can be further divided into two categories depending on their training data requirements. De-identifiers that require training data impose significant burden on their users demanding a large set of clinical documents annotated in compliance with their prerequisite format.

NLM Scrubber is a freely available automatic clinical text de-identification tool with full support by its developers. Furthermore, it does not impose any annotation requirement on clinical scientists; i.e., no text to be annotated to run the application for producing de-identified clinical reports. Although we continuously add sophisticated functionalities to NLM Scrubber, we strive to keep the user interface as simple as possible so that novice users can operate it easily. NLM Scrubber is a product of several years of studies on clinical text de-identification.1 2 We recently rewrote NLM Scrubber converting it from a pure research product to a consumer product. The user needs to fill out a short form stating mainly where the text files are located in the computer. At this point in time, it can accept only ASCII text reports formatted with proper capitalization; i.e., it would not perform well on all lowercase or all uppercase text.

The system is available on three platforms: Windows, Linux, and Mac OS X. It can be downloaded from http://scrubber.nlm.nih.gov.

Funding and Competing Interests
This work was supported by the Intramural Research Program of the National Institutes of Health, National Library of Medicine. The first author receives royalties from University of Pittsburgh for his contribution to a de-identification project. NLM’s Ethics Office reviewed and approved his appointment.

Health Information Technology Evaluation Studies: Trends in Communities and Geography from 2004 to 2014

Marjorie M. Kelley, RN, MS¹, Xiaonan Ji, MS¹,², Gina Torelli, BS³, Po-Yin Yen, RN, PhD¹
¹Dept of Biomedical Informatics, ²Dept of Computer Science & Engineering, ³Dept of Industrial Engineering, The Ohio State University, Columbus, OH

Introduction

Health information technology (HIT) use is increasing, as is evaluation of these technologies. But barriers remain. Using previously outlined definitions of “health information technology (HIT)” and “evaluation research”¹,², we aim to investigate trends in HIT evaluation research between 2004 and 2014 to inform future empirical evaluation research. We hope to inform the research process in an effort to eliminate these barriers in HIT evaluation studies.

Methods

We searched PubMed for journal articles published between 2004 and 2014 for HIT evaluation studies using inclusion and exclusion criteria described by Ammenwerth and de Keizer³. We looked for trends in research groups, author geography, journal name, and the number of HIT evaluation research articles. We also used a novel method to identify research communities. Using ArticleNet⁴, we generated an author network by calculating author similarity for each article pair. This author network identified common authorships among our cohort of articles. We used visualization software to detect dominant communities. Communities with highly connected article nodes shared high author similarity. To better visualize the network, different communities are displayed in different colors with node size representative of author publication activity – larger nodes mean more common author linkages. Contributing authors from the same community, with high collaborative relationships, are detected as “research groups”.

Results

A total of 5,120 articles were found. After applying inclusion/exclusion criteria, 1,624 references remained. Our analysis revealed the largest community (G1) as having the most publications and most common authorship activity. Dr. David Bates, Harvard Medical School, was the most active community member. The largest community (G1) shared significant activity overlap with the 6th largest community (G5). In the second largest community (G2), Dr. Suzanne Bakken, Columbia University, was most active. Interestingly, in the third largest community (G3), authors were active within their own community, but only a few interact with authors from other communities. Three small communities (G4) had no activity with other communities. Studies appeared most frequently in 5 publications: Studies in Health Technology and Informatics, Journal of the American Medical Informatics Association, International Journal of Medical Informatics, BMC Medical Informatics and Decision Making, and Applied Clinical Informatics. These journals published approximately one-third of the articles in our cohort. The number of articles more than doubled in the past 5 years as compared with the previous 6 years. Geographically, the majority of authors were from the U.S. (52.5%), with 29% of these from NY, MA and CA. Authors from NY, MA, CA, PA, MN, IL, TN, OH, MD and TX accounted for just under 65% of all U.S. articles. Interestingly, data imported from PubMed identified USA as country, but left state blank in 5% of cases. Data integrity were concerns.

Conclusion

This preliminary data informs our future HIT research evaluation studies, investigating study methodology, analysis, type of systems, and populations. We hope to identify experts in various HIT evaluation research communities as well as identify potential collaborative opportunities in multi-site HIT evaluation research.

Clinico-genomic Decision Support System for Precision Diagnostics and Management
Anuja Kench1, Vandana P. Janeja, PhD1, Amanda Niskar, DrPH2, Yelena Yesha, PhD1, Napthali Rishe, PhD3

1University of Maryland Baltimore County, Baltimore, USA, 2Arthritis Foundation 3Florida International University, Florida, USA

Introduction

The focus of this work is clinico-genomic decision support system for better diagnosing and managing chronic diseases. We propose a clinical decision support system for early diagnosis of chronic diseases (such as arthritis, Diabetes, Cardio Vascular Disease) and better disease management. We propose a generalizable framework, which can accommodate several distinct features coming into the system from clinical, genomic, environmental domains among others. We utilize this framework to discover similar patients and overlaps among patients in a set of these features which has several applications such as: (a) better cohort discovery for clinical trials, (b) better disease management by studying peer group of patients with similar diagnosis and better prognosis, (c) early disease diagnosis by studying similar features in patients with existing diagnosis

Approach:

The overall approach, as shown in the figure, looks at clinical data and performs clinical record extraction. The clinical data consist of the structured medical record, unstructured doctor’s notes, X-rays, lab data among other data components. Some studies have looked at extracting and integrating structured and unstructured data[BM15, G14]. However, our work focuses on integrating multiple types of data from multiple sources with different types of structure. Data is extracted from relational and non-relational forms. Similarly, genomic data is extracted from a large learning database and matched with patient specific genomic data. Databases like VINCI [VA2015] and dbGap[NCBI2015] contain such heterogeneous patients records that can be accessed under agreement. The genomic data is in the form of SNPs extracted from large databases [SW01] and prior clinical studies and patient specific genomic data. Data transformation and preprocessing is performed as new variables are introduced at different stages of the analysis.

The clustering of continuous variables and the categorical variables from clinical and genomic data are combined using a novel algorithm to form clinico-genomic clusters. Data within the clusters is evaluated to find partial or exact patient overlaps. The partial overlaps, especially overlaps above a certain threshold may indicate a high level of similarity in majority of attributes but not in some attributes, which may be of interest to study especially if the overlap is in key clinical variables but not in genomic variables and vice versa. Patients with high overlaps may also be selected as a cohort for clinical trials. The level of similarity can be calibrated to identify various types of overlaps. In addition, multiple diseases can be studied together, to identify potential overlaps between patients from disease groups where no known overlaps exist. This can lead to the discovery of potential links between diseases with no known clinical connections and potentially lead to novel research.

Understanding the patient through visualization to improve provider-patient communication in hospitals: Know your patient to personalize your communication

Maher Khelifi, PharmD1, Logan Kendall1, Sonali Mishra1, Andrew Miller, PhD1, Ari Pollack, MD1, Barry Aaronson, MD1,2, Wanda Pratt, PhD3
1University of Washington, Seattle, WA; 2Virginia Mason Medical Center, Seattle, WA

Introduction: The problem of personalized patient-provider communication

Good patient-provider communication plays a major role in hospital quality of care (1). However, good communication requires that providers know not only the patients’ medical information, but also the patients’ communication needs (2). Clinicians tend to have more success when tailoring their messages to best match these needs. Patients have different personalities, values, and preferences; yet, providers have no easy way to understand these differences (3). This lack of knowledge of the patient could negatively influence the patient’s experience and possibly even cause harm. In our study, we aim to understand hospitalized patients’ values and preferences. With this knowledge, we can create a patient profile frame that can be used to visually highlight relevant patient values to providers. These visualizations could quickly give the provider an overview of the patient’s priorities and preferences. With this improved understanding, providers can provide personalized communication.

Methods:
We conducted 28 interviews and observations of adult and child patients and their caregivers across two sites: an adult tertiary care hospital and a children’s hospital. At each site, we conducted 40-60 minute semi-structured interviews with patients and their caregivers. Based on these interviews, we identified a list of possible concerns of the patient during his stay in the hospital. Then, we classified these topics into categories.

Approach: Visualizing Patient Characteristics

Based on prior research and our interviews with hospitalized patients, we identified 7 important categories that the provider has to consider to personalize communication with a patient: Self-efficacy, Privacy, Involvement of caregivers, Details and technical terms, Emotional needs, and Real-time updates (SPIDER). We propose visualizing these characteristics in a radar graph. The graph presents to the provider how much the patient values each of these components. (Figure 1). We hope these visualizations will provide a quick yet thorough view of each patient’s priorities and enable effective and personalized communication. We are conducting more interviews to confirm that our framework is broad enough to cover diverse patient experiences in a hospital. In addition, we seek to confirm that these graphs will be well suited to be incorporated into provider workflow.

Figure 1: How to use the SPIDER Graph?

To identify the patient’s preferences, the patient will be invited to answer a survey and based on his answers we can populate the SPIDER graph. This graph (on the left) shows that for Patient X, the provider has to consider that the caregivers are playing a key role in the patient care. The self-efficacy of the patient is low. So it’s better to communicate with the patient in the presence of his caregiver especially when taking decisions. The patient values knowing about updates and he has a high medical literacy. This means that it is preferable to tell the patient about the last updates about his health care, and it is tolerable to use some technical words with the patient.

Increasing Size of a Health Information Exchange Allows More Accurate Measurement of Early ED Returns

Eugene Kim, MD1, George T Loo, MPA, Tina Lowry, MS1, DrPH1, Bradley D Shy, MD1, Ula Hwang, MD1, Nicholas Genes, MD, PhD1, Cindy F Clesca, MA1, Lynne D Richardson, MD1, Jason S Shapiro, MD1

1The Department of Emergency Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Introduction:
Our group has previously shown that use of data from a health information exchange (HIE) for certain emergency department (ED) quality measures allows more accurate identification of outcomes than site-specific data from individual institutions.1,2 This is because HIE captures data from patient encounters across multiple sites and more accurately reflects the way many patients seek care—across multiple providers. We hypothesized that when two HIEs in the New York metropolitan area merged, that our ability to identify early (72-hour) ED return visits would increase with the larger, post-merger HIE data compared to the smaller, pre-merger HIE data (the latter being a subset of the former). In this study, we compare our ability to identify early ED returns with increasing levels of HIE by measuring 1) site-specific early ED returns with the initial “index” visit and the return visit at the same site, 2) pre-merger HIE-wide early ED returns with the index visit at any of the 10 sites in the original, smaller, pre-merger HIE and the return visit to any of the original 10 sites, 3) post-merger HIE-wide early ED returns with the index visit at any of the 10 original sites, but now with the return visit to any of the 31 sites in the larger, post-merger HIE, and 4) post-merger HIE-wide early ED returns with the index visit at any of the 31 sites in the larger, post-merger HIE, and with the return visit to any of the 31 sites.

Methods:
Data for all ED and inpatient visits from 3/1/09 to 2/28/14 were obtained from Healthix, an HIE in New York City. Data were cleaned and de-identified in accordance with Healthix and New York State policy and analyses were performed to identify the number of early ED return visits for each of the 4 analyses described above. Only ED visits were used for the index visit, but either ED or inpatient visits were used for the returns.

Results:
A total of 12,669,657 encounters across the larger post-merger HIE were used in the analysis, including 6,352,829 encounters from the smaller, pre-merger HIE subset. Site-specific early ED return rates (early ED return visits divided by all ED visits) ranged from 0.7% to 8.8% across all 31 sites (median 2.7%). Pre-merger HIE-wide data with the index visit at any one of the 10 pre-merger HIE sites and the early return visits at any of 10 sites across the HIE yielded early ED return rates ranging from 3.7% to 15.4% (median 5.65%). Post-merger HIE-wide data with the index visits at any one of the original 10 pre-merger sites and the early return visits at any of 31 sites across the new, larger HIE yielded early ED return rates ranging from 3.8% to 15.5% (median 5.7%). Post-merger HIE-wide data with the index visits at any one of the 31 sites and the early return visits at any of the 31 sites across the new, larger HIE yielded early ED return rates ranging from 1.8% to 15.5% (median 4.5%). The average total incremental increase in our ability to identify early ED returns increased by 66% going from site-specific data to measurement across all 10 sites in the pre-merger smaller HIE; and by 85% going from site-specific data to measurement across all 31 sites in the post-merger larger HIE.

Conclusions:
This analysis shows that with increasing data size of an HIE there was an incremental benefit in our application of a common ED quality measure. Compared with site-specific data, the average ability to identify early ED returns increased by 66% in the smaller HIE (10 sites), and by 85% in the larger HIE (31 sites). As local and regional HIEs merge and consolidate into larger nodes of aggregated clinical data, toward the eventual goals of state-wide and nationwide HIE, our ability to more accurately apply clinical quality measures should also increase. Further analysis should be done to determine if similar incremental benefits with larger HIEs are found for other quality measures such as 30-day hospital readmissions.

Usability of mobile apps for radiology diagnostic decision-making

Min Kim, PhD1, 2, Michael R. Aro MD3, Kraig J. Lage MD3, Kevin L. Ingalls MD3, Vivek Sindhwani MD3, Mia K. Markey, PhD4
1Department of Health Management and Informatics, University of Missouri2; University of Missouri Informatics Institute; 3Department of Radiology, University of Missouri, Columbia, MO; 4Department of Biomedical Engineering, The University of Texas, Austin, TX

Abstract

We evaluated the usability of eight iOS mobile apps currently available in radiology to support training in diagnostic decision-making. Lab-based usability tests using video analyses with the triangular method approach were conducted to determine usability issues. The methods include video analysis, system usability scale (SUS), and a debriefing session with participants. Six staff radiology physicians completed a typical set of tasks, using think-aloud strategy. Thirty-five unique usability issues were identified and 18 improvements were suggested.

Introduction

Radiology physicians are increasingly using mobile devices in image analysis for decision making. However, very few of the healthcare apps available on the market have been tested with respect to their usability. The purpose of this study was to identify and measure usability issues and collect suggested usability improvements from radiologists.

Methods

A multi-step review process was used to identify mobile apps that assist in education and training of radiological diagnostic decision-making processes in two major stores (Google Play and iTunes). From 381 apps that were initially identified, eight iOS apps that deal with a variety of radiology modalities were selected for usability evaluation. Three apps were available in both stores: (1) Case Review, (2) AART Ultrasound Cards Lite, (3) Dexnote, (4) Brain MRI Sectional Walker, (5) Diagnostic Radiology - Dynamic Approach to Abdominal Radiology, (6) MED imaging Case, (7) Radiology Assistant, (8) Radiology Head. The apps were installed on an iPad for data collection. Six staff radiology physicians performed scenario-based tasks in a lab-based setting. A mobile observation device was used to record screen activities and hand gestures, which allowed comprehensive capture of the human computer interaction.

Results

The SUS (0-100) score illustrated that physicians ranked the app’s usability at a mean of 67 (high marginal) and the score ranged from 41 (AART) to 76 (Diagnostic Radiology). Task analysis revealed 35 unique usability issues. The most frequent issue observed was inefficient navigation; most physicians had to spend extra time testing inactive functions due to non-intuitive or misleading labels, which was consistent with physicians self-reported 18 unique improvements.

Example recommendations were matched according to the usability principles suggested by mHIMSS (Table 1).

Table 1 Examples of suggested usability improvements and related mobile usability principles from mHIMSS.

<table>
<thead>
<tr>

<td>Efficient Interaction, Simplicity</td>
</tr>
<tr>
<td>“Things which require long clicks/double clicks are less intuitive. Small universally understood signs help for navigating through the app.”</td>
<td>Efficient Interaction, Consistency</td>
</tr>
</tbody>
</table>

Conclusion

This study (1) demonstrates the good example of usability evaluation, and (2) suggests potential improvements in the development of medical mobile apps in radiology education and training. Currently, there are no systematic and standard usability guidelines for mobile medical apps. Consequently, the approval process of the applications does not require a measure of usability. While SUS scores indicate the usability of the apps as acceptable, physicians reported some issues in this small pilot study. This suggests the urgent need of systematic usability evaluation for potentially improving user acceptance and achieving educational effectiveness. Further research is warranted involving different platforms (Google Play, Windows, BlackBerry) and varying sizes of mobile devices (smartphone, phablet) to achieve generalizability.
Improving Detection of Reasons Not to Take a Medication by Leveraging Medication Prescription Status

Youngjun Kim1,3, Jennifer Garvin, PhD, MBA2,3, Julia Heavirland3, Stéphane M. Meystre, MD, PhD2,3
1School of Computing, 2Department of Biomedical Informatics, University of Utah; 3VA Health Care System, Salt Lake City, Utah

Abstract: When automatically assessing heart failure treatment quality measures, identifying mentions of reasons not to take heart failure treatment medications in a patient electronic health record is important. We created machine learning-based sequential taggers to extract reasons not to take heart failure medications based on lexical features. When adding the medication prescription status as feature, performance improved with 41% F1-measure.

Introduction: Extraction of Heart Failure (HF) treatment measures from clinical records is a crucial step to evaluate whether HF patients are provided recommended care. The CHIEF (Congestive Heart Failure Information Extraction Framework) application was developed to extract left ventricular ejection fraction (EF) mentions and values, Angiotensin Converting Enzyme Inhibitor (ACEi) and Angiotensin II Receptor Blocker (ARB) medications, and reasons not to take these medications (RNM). The performance of EF and medication detection [1-2] was quite good. However, the extraction of RNM is still considered a difficult task because RNM are only rarely found in clinical records and usually in less structured formats.

Methods: As part of the Veterans Health Administration HMP (Health Management Platform) project, we developed a reference standard of 1,655 clinical notes manually annotated by domain experts. Among these notes, 790 were used for training and 865 for testing. RNM was less frequently mentioned than EF or medication information with only 204 mentions in the training set and 241 mentions in the test set. As a baseline, we created a rule-based system using a dictionary lookup approach with a manually-built list of RNM terms. We then built machine learning-based sequential taggers to detect RNM based on lexical features. As specified in our annotation guideline, a RNM was annotated most frequently when the patient was taken off an ACEi or ARB medication. This observation motivated us to also use the medication prescription status to improve performance of RNM detection.

Results: For the dictionary lookup, we compiled a list of RNM terms from our annotation guideline and existing standard terminologies. This rule-based system only reached low performance with a 5.3% F1-measure on test data. The machine learning-based sequential tagger models were trained with 135 notes containing RNM (about 17% of training data). When using features including medication prescription status as classified by one of the CHIEF module [2], our sequential tagger increased precision to 42.3% and the F1-measure reached 41%.

Table. Reason not to take medications detection results (Percentage)

Conclusion: This study shows that the sequential modeling outperforms rule-based system in detecting reasons patients are not prescribed evidence-based medication in this study. Our sequential tagger, incorporating medication prescription status that can be satisfactorily classified, allowed for improved performance.

Title: Analysis of the Great Divide Between Cardiovascular Risk & Health Scores

Bobbie Kite, PhD, MHS\textsuperscript{a}, Tasneem Motiwala, PhD\textsuperscript{a}, Philip Payne, PhD, FACMI\textsuperscript{a}

\textsuperscript{a}Department of Biomedical Informatics, The Ohio State University, Columbus, OH, USA

Problem:
Cardiovascular (CV) assessment may be performed through risk and health scores. CV risk scores are commonly used in a clinical setting to assess risk of cardiovascular disease (CVD). Cardiovascular health (CVH) scores are typically used in a consumer setting to assess individual lifestyle factors. CV risk and health scores are derived from disparate sources of data for different audiences. Variance in these factors creates voids between patient and clinician perceptions. These divides in turn, may translate into usability issues. Articulating this divide is the first step towards creating bridges and solutions.

Methods:
Using a population of approximately 35,000 members from The Ohio State University Health Plan, we characterized the CVH score along with Framingham 10yr Cardiac Disease Risk Score using clinical measurement guidelines and risk scoring algorithms for those with available data. A score was calculated for each eligible member per measure and population health metrics were formulated.

Results:
We were able to characterize 33,821 and 34,810 members for CVH in 2013 and 2014 respectively; and 23,858 and 27,725 for 10yr CV heart disease risk in 2013 and 2014 respectively. This represents a 9% growth in the portion of the population we were able to characterize for CVD risk in 2014. The average mean score for CVH in this population was 61.96% for 2013 and 62.38% for 2014; and the average CVD risk was 2.96% and 2.94% respectively. Where 18\% of the population was characterized with poor CVH (49\% or below), only 1.9\% of the population was screened with a high 10yr risk of CVD (>20\%). Conversely, only 12\% of the population was characterized with ideal (80\% or above) CVH and 88\% was screened with a low 10yr risk of CVD (<10\%).

Conclusions:
The need for a domain analysis of the divide between CV risk and health is necessary because consumers and clinicians utilize informatics based assessment tools receiving conflicting information. This situation is compounded by informatics issues such as missing data and variable granularity along with a lack of behavioral models within this domain. As we seek to answer research questions requiring usability of assessment tools, we can leverage informatics to bridge these divides. Next steps include a systematic review of clinician and patient motivations, related informatics, and appropriate applicable behavioral models.
The Scalable Collaborative Infrastructure for a Learning Health System

Jeffrey G. Klann, PhD1,2,3, Marc Natter, MD1,4, Doug MacFadden, MS1, Sarah Weiler, PhD1, Kenneth Mandl, MD, MPH1,4, Shawn N. Murphy, MD, PhD1,2,3

1Harvard Medical School, Boston, MA; 2Partners Healthcare, Boston, MA; 3Massachusetts General Hospital, Boston, MA; 4Children’s Hospital Informatics Program, Boston Children’s Hospital Boston, MA

Background
The Scalable Collaborative Infrastructure for a Learning Health System (SCILHS, pronounced “skills”) is a growing network of health centers across the United States, presently covering over 8 million patients at eleven sites. [1] SCILHS is a Clinical Data Research Network (CDRN) in the Patient-Centered Outcomes Research Institute’s PCORnet, a national effort to instantiate a ‘network of networks’ that supports large-scale comparative effectiveness research. [2] SCILHS has adopted the PCORnet Common Data Model (CDM) as its foundation for interoperable data exchange.

SCILHS uses Informatics for Integrating Biology and the Bedside (i2b2) as its technical backbone. i2b2 is an open-source clinical data warehousing and analytics platform funded by the National Institutes of Health. It is used at over 100 sites nationwide, including several CDRNs and the National Center for Advancing Translational Sciences (NCATS) Accrual to Clinical Trials (ACT) network. i2b2 supports live distributed queries through the Shared Health Research Informatics Network (SHRINE) platform, which SCILHS has adopted and enhanced.

System Description
SCILHS is enabling patient-centric clinical research through:

• **Live cohort-finding queries across all its sites with real-time results.** We developed an i2b2 ontology that represents the PCORnet CDM, and we created a mapping methodology using existing i2b2 components that allows sites to support this common ontology without changing their underlying data. By developing a mapping to this ontology (the SCILHS CDM), sites can participate in the SCILHS SHRINE, which provides a graphical query tool to develop and execute prep-to-research queries across all sites in real time. We have made our ontology publicly available, and portions of it are being used at several other CDRNs. [3]

• **Incorporation of patient reported outcomes data with clinical data.** An emerging need in clinical research informatics is the inclusion of patient reported outcome (PRO) information in research data, such as subjective evaluation of quality of life with chronic disease. The mySCILHS platform provides a framework to gather and integrate PROs with i2b2. Patient survey questions are defined in the popular Research Electronic Data Capture (REDCap) tool, and a combination of REDCap and a commercial telephony platform (CXP, Aspect Software, Inc) are used to survey patients. The PROs gathered via telephony from patients assigned to REDCap surveys are delivered to an i2b2 Loader service that stores the data in an i2b2 repository. We have implemented surveys that focus on quality of life and symptom burden for these diseases in conjunction with clinical experts.

• **Interoperability with the PCORnet Distributed Research Network for nationwide data analytics.** We developed a tool that transforms data in an i2b2 repository into the PCORnet CDM tables that are used for PCORnet DRN queries. This tool relies on the mappings developed to support the SCILHS CDM, so an automated process enables DRN interoperability at compliant sites. Seven of our sites have transformed their most complete data into CDM tables and have successfully responded to DRN queries made through the PopMedNet query tool.

Discussion
SCILHS is paving the way for large-scale patient-centric comparative effectiveness research, building on 15 years of informatics innovations. It offers a common data model that can be implemented without changing underlying data, real-time query results, interoperability with the PCORnet Distributed Research Network, and a telephony framework for gathering and incorporating patient reported outcome data.

Mixed-Methods Study of Risk Communication in a Patient Decision Aid

Krystal A. Klein, PhD, Lindsey Watson, BS, Latha R. Kalaga, MS, MBI, Karen B. Eden, PhD
Oregon Health & Science University, Portland, Oregon, USA

Introduction

Overall, patients who used patient decision aids—evidence based tools designed to educate patients about their options concerning a specific medical decision—in conjunction with typical care have superior knowledge and risk comprehension scores relative to patients who receive care as usual.¹ The details of how to communicate risk to patients within a patient decision aid must be carefully considered on a case-by-case basis. Currently, risk communication is as much an art as a science, despite a growing literature that maps the effects of risk formats, viewer characteristics, and chart types on outcomes such as perception of risk levels, gist or exact recall of risk statistics, and decision outcomes (i.e., application of risk knowledge). This mixed-methods study recorded the impressions and reactions of rural patients, in their own words, to quantitative risk information in Mammopad², a mobile app patient decision aid for women in their forties to help them decide at what age to begin having routine screening mammograms. Through this study, we aimed to gain understanding of the role and perceived importance that risk information in a decision aid has in a medical decision-making experience. Simultaneously, we investigated the effectiveness of Mammopad’s specific risk communication graphics, by probing recall of key statistics and success at answering a word problem that required application of the presented risk information.

Methods

Risk presentation quality was evaluated in three pieces: 1) A risk scenario question where participants answered a word problem with their quantitative estimate of the positive predictive value of screening mammograms for women in their forties (administered before and after using the decision app); 2) A thematic analysis of transcripts from interviews with a subsample of Mammopad participants about what they found valuable about quantitative risk information; and 3) A thematic qualitative analysis of transcripts from the same interviews about the interpretation of risk communication diagrams, including misperceptions/misinterpretations of data.

Results

Estimates of positive predictive value of mammography by participants (n=71) were more accurate after using the aid than they guessed before using it, although that was partly due to confusion between different risk statistics presented in the decision aid. Twenty-one participants enrolled in the interview phase: twelve participated in an interview session within an hour of using Mammopad, and nine others were recalled weeks or months after first using Mammopad. Our analysis discovered the following negative themes concerning numeric risk presentation: 1) lack of gradations in perception of uncertainty based on numbers, 2) numbers are sometimes provided as explanation, instead of a tool for explaining, 3) skepticism about the value of numeric information in light of forgetting, and 4) confusion about different statistics. Positive themes were that the women: 1) valued grounding in real-world groups, 2) valued a connection to medical research, and 3) valued transparent enumeration of outcomes. A simple breast cancer incidence pictograph was well comprehended by participants, and recall for risk information was good shortly after using the aid (but quite poor after a latency of weeks or months). A more complicated flow-chart graphic was miscomprehended in several different ways that we present here.

Conclusion

The numerical risk graphics in Mammopad were well received and informative, although not memorable on a long-term basis. It may be helpful to administer Mammopad at multiple times during a patient’s forties to refresh her memory. The more complicated of the two risk graphics in Mammopad was less often completely read or comprehended by participants, but cognitive tools such as animation could ease the cognitive burden of comprehending this information and improve understanding.

Interactive Voice Response Technology: Promises and Pitfalls in Facilitating Patient-Reported Monitoring for Adverse Drug Reactions

Elissa V. Klinger, MS1; Alejandra Salazar, PharmD1; Jeffrey Medoff, BS1, Mary Amato, PharmD1,3, Patricia Dykes PhD1, Jennifer S. Haas, MD1,2; David W. Bates, MD1,2; Gordon D. Schiff, MD1,2

1 Division of General Internal Medicine and Primary Care, Brigham and Women’s Hospital, Boston, MA; 2 Harvard Medical School, Boston MA; 3 Massachusetts College of Pharmacy and Health Sciences, Boston MA

Introduction: We developed a patient-reported, interactive voice response system (IVRS) to actively monitor the safety and effectiveness of treatment for patients taking FDA-approved medications for one of four common chronic conditions (diabetes, hypertension, insomnia, depression), with real-time support by a pharmacist. We present an analysis of our experience highlighting promises & pitfalls associated with this technology and offer strategies for other healthcare organizations that might seek to create a similar patient-reported outcome platform.

Methods: We identified and described 6 major activities in the deployment of an advanced IVRS platform: (1) developed an algorithm to identify primary care patients who had newly started a target medication; (2) created an IVRS-delivered data collection tool that included consent, patient ID, broad /targeted symptom screening with branching logic, and live-transfer to a pharmacist; (3) worked with in-house telecommunications to ensure appropriate caller IDs & patient dial-back routing; (4) created workflows to capture IVRS patient-reported data to pre-populate the pharmacist database for symptom validation and intervention documentation; (5) fired alerts off of positive responses to queries about symptoms; and, (6) developed an in-house customer-service platform to provide support/assistance with calls and an opportunity to opt-out in real-time.

Results: Of 4,847 eligible patients called by IVRS, 609 (12.6%) participated & provided data; 309 reported positive symptoms DQGZHUHWUDQVIHUUHGWRWKHSKDUPDFLVW:KLOHWKLVGHPRUQWU PDWHV³VXFFHVV´LQWKHRSHUDELOLWDQG, the platform we describe is not without challenges, for both end-users and the healthcare system into which it is embedded. Of 25,670 potentially eligible patients identified in our EHR, 11,945 (46.5%) were eligible true new target drug starts, illustrating the challenge of correctly identifying patients in an EHR who accurately qualified for the intervention (e.g., many apparent new starts actually started outside our system). The rigidity of a structured & inflexible IVRS was confusing and frustrating. Patients had privacy concerns; although sent a letter in advance, some objected to seemingly unannounced calls and reported that they would have preferred knowing content in advance. Future interventions might inform patients about planned calls at the time of their clinic visit, thereby allowing opt-in/out and creating the expectation of the call as part of or an adjuvant to their care. Overly-complex branching logic in IVRS data collection tools made the calls long and created misunderstanding; patients are more likely to hang up the longer the call continues without resolution, thus affecting data quality and subsequent clinical action. Pre-loading outbound calls with specific patient data (without compromising confidentiality, should someone other than the patient answer the phone) is a step toward personalization, and underscores to need for accurate algorithms to identify appropriate patients. Email alerts that fired based on patient-inputted information were an important step in notifying team members about actionable data in real-time; however, the alerting system was undermined by delays due to web traffic and firewall “hops.” Caller IDs from the IVRS server should be “replaced” so that the hospital/health system name appears; any patient call-backs must route directly to a live person or a mailbox checked routinely, a requirement that we achieved only midway through the project. Pharmacist interventions included filing a templated note manually in the EHR. For patients who did not talk to the pharmacist but reported a symptom, data did not enter the EHR; ideally all patient-reported data would interface seamlessly. Providing real-time customer service is an essential component to the success of any automated call platform. The option to talk to a live person immediately at any point during the automated call should be considered for any IVRS intervention in which patients may require further assistance. Finally, the comparative effectiveness of IVRS technology vs. other forms of efficient/automated synchronous and asynchronous communication to capture patient-reported outcomes needs additional research, particularly in light of the myriad issues that IVRS raised, and may make other approaches better to try.
Text Mining of Patient Demographics and Diagnoses from Psychiatric Assessments

Eric J. Klosterman, M.S.¹,², Rashmi Prasad, PhD²

¹Rogers Memorial Hospital, Oconomowoc, WI; ²University of Wisconsin-Milwaukee, Milwaukee, WI

Introduction: The present work contributes to the currently understudied application of text mining from narrative texts of psychiatric assessments, by exploring keyword-based pattern-matching and Natural Language Processing (NLP) methods for automatic extraction of patient demographics (age, gender, marital status, and education level) and Axis I admission diagnoses, which are all also automatically assigned a code. Applications of such systems include determining patient outcomes and eligibility for clinical trials. While there has been research on the automatic extraction of medical diagnoses [1], none yet has dealt with psychiatric diagnoses, and work on extraction of patient demographics are limited in both depth and scope [2].

Methods: 200 manually de-identified admission psychiatric assessments of patients from a mental health hospital (Rogers Memorial Hospital (Oconomowoc, WI)) were manually annotated (double blind) by two annotators with extensive experience in reviewing psychiatric assessments for coding purposes. Annotation involved code assignment to each document, and marking text spans indicative of each code. Separate algorithms were developed for each information category over 110 documents used as the development (dev.) set, with the remaining 90 documents used as the test set. Keyword-based pattern matching rules were first applied, and then augmented with NLP-based rules (defined over constituent trees and typed dependencies obtained with the Stanford Parser [3]), to improve performance. Results: Evaluation, over the dev. and test sets, used two metrics of code accuracy (No. of correctly coded documents/No. of total documents) and text accuracy (No. of documents coded with positively matched text/No. of total documents). We found that age and gender appeared consistently in semi-structured document sections and were almost entirely identifiable using patterns, with code and text accuracies above 98% in both dev. and test sets. Detection of (primary) diagnoses text spans and their coding was also done with a pattern-based approach, but the performance dropped from 99% in the dev. set to 92% in the test set. Some errors resulted from patterns but others occurred primarily because the UMLS Metathesaurus DSM-IV vocabulary used to detect diagnoses strings was not comprehensive enough to account for the wide variation in the observed terms. Education level and marital status, located in the unstructured portion of the narrative, were the most challenging because of the wide variation in their linguistic expression. Results (Table 1) show that structural rules improved both code and text accuracy, although there was a more significant drop in performance from the dev. set to the test set for education level than for marital status, indicating the need for better generalization of the rules for education level. Results for the pattern-based approach for marital status indicate that better performance on text span identification does not correlate with better code accuracy since spans can contain negations and modality that affect the code assignment.

Conclusion: A text mining method combining keyword-based patterns and rules designed over sentential constituency and dependency structures can achieve high accuracies for extracting patient demographics and admission diagnoses from psychiatric assessments. Limitations arise from errors in pre-processing components, inadequacy of terminological resources for term coverage, and generality of the rules themselves. This study makes a novel contribution to text mining work in the psychiatric domain, with promising initial results.

Abstract
In this research we document the challenges and lessons learned during the development of the BigMouth dental data repository. BigMouth uses the i2b2 framework and contains EHR data from six dental schools. We faced various challenges including: a) issues related to the multi-institutional nature of the project, b) data modeling and integration issues and c) infrastructure related issues. BigMouth DDR is one of a kind data repository in dentistry that could serve as an important resource for research.

Introduction
BigMouth Dental Data Repository (DDR) is an inter-school dental data repository that contains data from the axiUrn Electronic Health Record (EHR) used at six dental schools which are part of the Consortium for Oral Health Research and Informatics (COHRI). BigMouth provides researchers with a single large database to advance evidence based dentistry. BigMouth was built on the Informatics for Integrating Biology and the Bedside (i2b2) data warehousing platform. Extracting and loading data from six different institutions present unique challenges. The purpose of this research is to report on the different challenges faced during the development and the approaches undertaken to address these issues.

Method
A set of configurable scripts that extract data from the axiUrn EHR were created during the start of this project. Each school was provided with these scripts during the project release. The schools ran these scripts against their EHR instance to produce a set of Comma Separated Values (CSV) files that corresponded to the database tables in i2b2. These files were securely transferred to UTHealth and loaded into BigMouth using a data integration tool called Talend. Once completed, users from the participating schools can securely authenticate into BigMouth using a federated identity management solution provided by InCommon. Each user has access to the complete dataset extracted from their school and also to an integrated terminology system that allows users to query data across all schools that contribute data to BigMouth. The integrated terminology hides the source information providing the schools full control over their data.

Challenges and Solutions
Collaborating with multiple institutions came with various logistic challenges such as communication delays, educating remote teams about the settings, execution of data extraction scripts, debugging, data cleaning and terminology mapping. In order to minimize the impact of these issues on the development of the repository, we adopted a centralized data integration approach where data are refreshed on a half yearly basis providing us the opportunity to perform data quality checks. These quality checks includes manual sanity check using a checklist and scripts that compare new data with the previous release to ensure no data are corrupted or lost.

A common problem in data integration is the representational heterogeneity of data. Data from different sites contain a) Content differences – granularity or level of information captured b) Naming differences – use of synonyms etc. c) Semantic differences – meaning of same term varies based on the context in which it is used. As a solution to these problems, two views were developed that can be seen by the users in the user interface. A user can either query for data at their own school by using the local terminology that they are familiar with or query data across all sites using an integrated terminology called the COHRI terminology. Each folder in the COHRI terminology was either adopted from standard terminologies or developed from the scratch. Standard terminologies were used for diagnosis and procedure information. For the rest of the concepts like demographics, periodontal and forms data, a standardized terminology system was developed with the help of domain experts at COHRI. In fact, this effort encouraged COHRI members to collaborate and create standard forms for medical history, dental history and caries risk assessment. As of March 2015, BigMouth contains data on over 2 million patients from six institutions. The infrastructure is being constantly evaluated, tested and upgraded based on the performance needs.

Conclusion
BigMouth contains EHR data from six institutions that are being used for research and advancement of evidence based dentistry. The basic data extraction and loading processes have been refined since the initial development of the project. This has resulted in the creation of a scalable infrastructure that can provide a robust platform for future addition of data from dental institutions.

A Novel Visualization for Rapid Summarization of Patient History: Application to Cirrhosis

Jejo Koola\textsubscript{1,2}, Samuel B. Ho\textsubscript{3,4}, Michael E. Matheny\textsubscript{1,2}

\textsuperscript{1}Tennessee Valley Healthcare System, Dept. of Veterans Affairs, Nashville, TN
\textsuperscript{2}Vanderbilt University, Nashville, TN
\textsuperscript{3}University of California at San Diego Medical Center
\textsuperscript{4}Dept. of Veterans Affairs, San Diego, CA

BACKGROUND: Patient phenotype identification serves as an essential step for clinical trial recruitment, outcome prediction, survival analysis, and other retrospective and prospective research studies. Physicians diagnose chronic diseases and interpret severity of illness by interpreting the large volume of clinical information available in the patient’s electronic health record (EHR).

OBJECTIVE: We sought to develop a visualization to succinctly summarize a patient’s clinical history relevant to advanced liver disease progression to support rapid clinical interpretation.

METHODS: A radial layout with the time axis along the circumference was developed to represent the evolution of key clinical information values. Concentric rings within the visualization model represent input features. Continuous variables, such as laboratory tests, were mapped from normal to abnormal in the direction of expected liver disease using a color scale from green to yellow to red. Categorical information, such as inpatient admissions, outpatient visits, and radiology studies were mapped to discrete markers. The D3 JavaScript engine was used because one can develop an interactive user interface that allows drill-down and changes in representation by the user. As a pilot, we analyzed a retrospective cohort of patients receiving care at the Dept. of Veterans Affairs between 2005 and 2013. We selected patients with known risk factors for cirrhosis (based on ICD 9 code) who developed advanced liver disease during the study time period. We extracted and modeled 7 features: creatinine, albumin, Model for End-Stage Liver Disease (MELD) score, bilirubin, platelet count, prothrombin time, and inpatient admission dates.

RESULTS: Figure 1 represents the results of the visualization tool for one of the sample’s selected patients. The patient evinces a pre-cirrhosis phase between 2005 and 2007 where liver function is normal. During this time the patient’s main risk factor for developing liver disease was Hepatitis C. In late 2007, the patient showed the first signs of liver dysfunction, and had an inpatient admission for the purposes of a liver biopsy. The patient then has a stable quiescent phase between 2008 and 2009. Starting from early 2009 the patient enters a progressive decline in liver function until he expired from cirrhosis complications in mid-2010. The individual rings allow for clear determination of these distinct clinical situations.

DISCUSSION: Cirrhosis is a complex, sometimes progressive, fatal disease. Though liver biopsy serves as the gold standard, more commonly, physicians use laboratory values, clinical history, and radiology to make the diagnosis. Overall, this pilot work highlights that thoughtful visualization allows the display of complex clinical information representations over an extended time period. Healthcare providers and secondary data users can quickly identify these disease state changes for use in clinical care as well as annotation and chart review purposes.
**Clostridium Difficile Repeat Ordering Difficult to Control without CDS**

Vishnoo Charan Reddy Kothapeta, MBBS, MBA¹, Alfred Caligiuri, PA, MBA¹, Kevin Bock, MD, MHCDS¹, Michael Oppenheim, MD¹, Eytan Behiri, MD¹

¹North Shore-LIJ Health System, Lake Success, NY

**Introduction**

CDC-approved latest guidelines discourage repeat Polymerase chain reaction (PCR) testing in patients suspected of or diagnosed with Clostridium difficile infection (CDI). However, at North Shore LIJ Health System, there had been a significant number of repeat orders for C. difficile Toxin by PCR. System-wide policy is to place any patient with a C. difficile Toxin by PCR order in private bed isolation leading to resource wastage. The Computerized Provider Order Entry (CPOE) system with embedded Clinical Decision Support (CDS) has provided an opportunity to improve adherence to evidence-based knowledge guidelines. Since duplicate order checking is not specific enough in this clinical scenario, hard stops were used for blocking repeat orders, as they have shown to be more effective than “soft” alerts in preventing adverse events.

**Method**

Intervention: To reduce repeat orders, a Medical Logic Module (MLM) was designed and implemented at hospitals which use Allscripts’ Sunrise Clinical Manager as the Electronic Health Record (EHR) system. A hard stop (blocking the order) was implemented to block the provider from placing a new order in the CPOE system; if the patient has a recent result of either a negative within the previous 3 days or a positive within the previous 3 weeks. The provider is shown an alert message to inform that a recent result is available. Additionally, there was education and outreach to inform providers of these new policies.

Study Design, Setting: This is an uncontrolled interventional study analyzing effects of the hard stop on C. difficile orders during the following periods: four months prior (7/15/2014 to 11/11/2014) to implementation, four months after (11/12/2014 to 03/11/2015) implementation and the previous year (11/12/2013 to 03/11/2014) to compare season variations. Medicare/Medicaid reimbursement ($50.27) was used to calculate lab savings. Excess cost of a private bed ($148.75) was calculated using pricing information from Rochester General Health System, NY.

Data Collection and Statistical Analysis: Data related to the number of orders placed, orders blocked and alerts displayed were obtained by SQL queries and exported to Microsoft Excel to conduct an unpaired t-test analysis.

**Results, Lessons Learned, Key findings**

A two-tail p-value of less than 0.05 was considered significant. Statistically significant decrease is observed when post intervention data (1174 orders) was compared with pre intervention 1528 orders (p-value = 0.003) and with last year’s 1863 orders (p-value < 0.001). Prior to MLM implementation, 125 repeat orders were placed including 6 paper orders. After implementation, there were still 33 repeat orders and the number of block-able CPOE orders dropped to 20 (orders outside the scope of current MLM).

During the study period, 230 alerts were displayed to block 117 orders of which 65 orders were for patients who had a previous negative result. This is a $9,668.75 reduction in resource wastage by not assigning private beds; assuming that the only change in treatment modality is private bed isolation. Additionally, laboratory resource utilization was reduced by $5,881.59 which yields a 4-month total of $15,550.34 resource improvement for the health system.

**Discussion – Key conclusions**

The MLM intervention achieved a statistically significant decrease in the number of orders by creating a full hard stop. In an ideal world, a provider should gain immediate value from an alert displayed. Hence, to reduce clicks or provider effort to review the referenced result, an improvement to the existing alert would be to show date and time of the result as well. While education and outreach can create a change in a provider behavior pattern, a CDS forces providers to adhere to evidence based medicine and the return on investment is larger. CDS can be effective but if overdone, can lead to a clinically important treatment delay which would gravely affect quality of care. The key to CDS is moderation and effective use with the right balance as to not affect clinical outcomes.

A Lifecycle Management Solution to Manage Mississippi’s Data Lake and Big Data Analytics Platform

Denise D. Krause, Ph.D.
University of Mississippi Medical Center;
Office of Mississippi Physician Workforce

Background. Mississippi leads the nation in poor health outcomes in several indicators. Many investments have been made to address individual health outcomes in Mississippi with minimal return on investments. To establish measurable baselines and inform interventions, we have built a managed data lake and big data analytics platform from which to address these major challenges.

Problem. The most immediate challenge was how to manage the deluge of data. We continue to accumulate data from many different contributors from organizations across the state and collect publicly available datasets relevant to health planning.

Objective. In order to manage the lifecycle of massive amounts of data, our objective was to develop a web-based lifecycle management (LCM) application, not only for master data management, but also to manage our custom applications. Specific aims were to:

1. Design and build a Microsoft SQL database to store data files.
2. Build in security to limit access to the database.
3. Develop a front-end interface to manage data files. This web application is used to log all raw data and then track these data throughout the processing phase along with detailed revision history, and in some cases loaded into the data warehouse.

Methods. A number of technologies were used to develop the LCM application, including Visual Studio 2012, C#.Net, ASP.Net MVC5, SQL Server 2008 R2, and others. The web application was built to be scalable to accommodate all aspects of data and application management within the LCM site.

Conclusion. This custom lifecycle management application enables us to continue to build the data lake and applications, while effectively managing contributions, modifications, and custom applications. Implementing an LCM application to organize and manage all types of data is a critical first step to realizing the value and potential a big data platform has to offer.
Visual Exploration of Temporal Data in Electronic Medical Records

Josua Krause¹, Narges Razavian, PhD¹, Enrico Bertini, PhD¹, David Sontag, PhD¹

¹New York University, New York, NY

Introduction and Background

Electronic medical records (EMRs) and administrative data contain a large number of distinct events happening in the life of a patient, including diagnoses, procedures, medications, and lab test results over time. Visualizing this data would be useful for clinicians to quickly comprehend a patient’s past medical history, and for researchers to design predictive models, better understand chronic diseases, comorbidity patterns, and contributors of health care cost.

Methods

For the visual representation of a patient’s history we display every event as a dot (see Figure 1a), similar to LifeLines¹. The color of the dot represents the group of the event, i.e. a diagnosis, a performed procedure, a lab-test result, a prescribed medication, etc. The horizontal position of a dot shows the day, whereas the vertical position distinguishes between different types of events. A significant contribution is to sort the types by the first occurrence in the history of the patient. This order is helpful for using the data to form causal hypotheses. Additionally, it helps with identifying major incidents (indicated by a steep rise) and allows for the visualization of a larger number of types than in previous work. Since the space for labeling events by type is limited, we use this fact in combination with the cost of an event (indicating the importance) to select which labels to display. Additionally, a user can use an interactive “lens” to hover over events of interest to show their labels (see Figure 1b). To reduce vertical space requirements we also provide different levels of aggregation according to the CCS hierarchy for diagnosis and procedures. The software is web based using a flexible format allowing for multiple datasets as input. We developed the system using health claims from a private insurer, and also the semi-synthetic data set from CMS².

Results and Discussion

The tool proved to be helpful for analyzing the output of machine learning algorithms in predictive healthcare analysis. It provides a quick way to identify the problems of an automatically generated model by looking at patients that were classified wrong or turn out to be outliers in the cohort. Additionally, the tool enables clinicians to quickly “tell the story” of the patient using just the administrative data often found in insurance claims.

Figure 1a: Overview of the system. At the top general information about the patient is displayed. The main view shows events of the patient’s history. The view area can be zoomed into providing a more detailed view. Blue stripes indicate hospital stays. On the left the CCS hierarchy of events happening in the timeline are shown. To give an impression about the frequency and importance of a type its occurrences along the timeline are also encoded here, shown as colored lines for each occurrence. At the bottom the sum of all costs of one day are shown as histograms.

Figure 1b: A user can use a lens to get information about events she is interested in. The horizontal granularity of single events is by day and the vertical position is determined by the first occurrence of the particular event in the history of the patient.

Problem List Quality in Ambulatory Medicine
John C. Krauss, MD, University of Michigan, Ann Arbor, Michigan

Introduction. The diagnosis based problem list is the cornerstone of problem oriented charting, and maintenance of the problem list in structured language is a core measure of the Meaningful Use program. There is not a harmonized definition of a problem list, with ONC defining the problem list as “the current and active diagnosis, as well as the diagnosis relevant to the current care of the patient, and if there are no active diagnosis, an entry indicating that has to be made”, while The Joint Commission has a similar metric called the problem summary list which includes “any significant medical diagnosis and conditions, any significant operative and invasive procedures, and adverse or allergic drug reactions, any current medications, over-the-counter medications, and herbal preparations”. There are also different standards for the frequency of updating the problem list, with one update during the reporting period required by Meaningful Use, while TJC requires updating whenever “there is a change in diagnoses, medications, or allergies to medications, and whenever a procedure is performed.” Given the conflicting requirements by certifying entities for the definition of a problem list, the different frequencies with which the problem list needs to be updated, and the lack agreement on criteria for assigning a diagnosis to a patient, there is considerable confusion as to the use of the problem list in the EHR. 1

Methods. A chart review was conducted to evaluate how the problem list was being used after installation of a certified EHR (Epic Ambulatory). A total of 86 charts were reviewed: 71 charts at a single encounter from 9 oncologists, and 15 charts before and after an encounter from 5 primary care providers. The University of Michigan imported problem summary list items from the legacy system into Epic as structured diagnosis at the time of go-live, and these chart reviews were conducted 14-16 months after go-live. For the oncology chart reviews, a single encounter was reviewed shortly after closure of the encounter and the items on the problem list were tabulated as to inclusion of the cancer diagnosis, duplicates, signs and symptoms, and surgical history. For the primary care chart reviews, the appearance of the problem list was captured immediately before and immediately after the encounter, and changes to the problem list were noted, as well as the number of items, and the type of items included on the problem list. The accuracy of the problem list was ascertained by reviewing the entire medical record.

Results. The 14 providers wrote notes on all of the encounters; in those charts, there were 1-30 structure language diagnoses included on the problem lists. Despite the “mark as reviewed tab” being checked for 95% encounters, most of the problem lists contained errors. Those errors included 73% of the lists with duplicate diagnoses. 60% of the lists with signs and symptoms that could have been better described as a unifying disease, and 10% of the problem lists contained surgical history items. For the 15 charts reviewed before and after an encounter, 40% of the providers made a change to the problem list. For the more in depth chart reviews, all of the listed problems could be confirmed by data in the medical record, but 60% of the patients had active problems that were not added to the problem list. The problem list was not included in the soap notes of any of the providers.

Conclusions. The lack of a harmonized definition of a problem list, the difficulty in incorporating problem list maintenance into EHR workflows, and the difficulty of determining which diagnosis are significant enough to be included in the problem list all contribute to low problem list quality. A low quality problem list can have numerous adverse consequences, including inappropriate activation of clinical decision support tools, inaccurate reporting to registries, and incomplete representation of the entire patient by the medical record. Efforts to engage physicians to curate and update the problem list without adding to physician workload may improve problem list quality and provide a more accurate summary of the patient.

Errors with Manual Phenotype Validation: Case Study and Implications

Polina Kukhareva, MS, MPH1, Catherine Staes, MPH, PhD1, Tyler Tippetts1, Phillip Warner, MS1, David E Shields1, Heather L Mueller2, Kevin W Noonan2, Kensaku Kawamoto, MD, PhD, MHS1

1Department of Biomedical Informatics and 2University of Utah Medical Group, Univ. of Utah, Salt Lake City, Utah, USA

Abstract

Human review is generally considered the gold standard for validating computer-generated phenotypes. This work provides a cautionary case study in the context of expert chart audits conducted to validate electronic clinical quality measures for enterprise use. We found that 8.7% (176/2034) of original human review results had to be modified following initial validation. Here, we describe the most common reasons for these modifications and discuss implications for establishing a systematic electronic phenotyping validation framework.

Introduction

Electronic phenotyping entails the automatic identification of cases which satisfy specific conditions. Currently, there is no standard framework for electronic phenotyping validation. While validating quality measures for enterprise implementation at the University of Utah Health Care, our group initially developed an ad hoc validation methodology that was not sufficiently robust. We neither selected cases randomly, nor did we ensure an adequate mix of positive and negative results. To improve the quality of our validation strategy, we (1) evaluated the accuracy and reliability of our initial validation approach and (2) developed requirements for a new electronic phenotyping validation framework.

Methods

Electronic phenotyping for HEDIS quality measures was performed using a clinical decision support-based quality measurement (CDS-QM) framework [1]. Human review was performed by an individual with 16 years of chart review experience (HM). Quantitative and qualitative methods were used to analyze error types and rates for human chart review results. We employed a user story mapping technique to create requirements for a systematic validation framework.

Results

Initially, 2034 electronic numerator-denominator results were evaluated by human chart review. Among the 167 mismatches between electronic and human phenotyping, 14 (8.4%) mismatches were due to errors in human evaluation. After correcting the quality measure implementation, an additional 162 (8.7%) mismatches were identified among the 1867 results that were matched during the initial validation process. Overall, 8.4% of the humanly-reviewed results had to be changed. The reasons for errors in human evaluation differed among the HEDIS quality measure types (Figure 1).

User story mapping analysis showed that in order to provide the best results, the validation framework should enable the following: (1) choose a representative, stratified random sample of electronic phenotyping results for human review; (2) include blind validations into the sample to avoid any potential bias resulting from the validator knowing the electronic results; (3) include intermediate results to simplify validation; (4) include a mix of positive and negative cases; (5) record reviewer’s comments, credentials, and dates of review; (6) use up-to-date human review results for ongoing and automated system validation; (7) account for cases where evaluation results are expected to change in the future (e.g., when a new data source is made available), and (8) deprecate and archive old validation results.

Conclusion

Human chart audits may result in errors, especially for highly complex algorithms and the identification of rare events (e.g., rare exclusion conditions). A systematic phenotype validation framework must account for these tendencies.

Integrated Health Information Architecture to Facilitate State-wide and National Evidence-Based Public Health Monitoring: A Case Study based in India

Manish Kumar, M.Sc., Rohit Ramaswamy, Ph.D., and Javed Mostafa, Ph.D., University of North Carolina, Chapel Hill

Context
The fact that significant investments are made toward large-scale health programs both at national and state levels requires close scrutiny of such programs based on routine surveys and data collection operations besides increased use of data for decision making and policy formulation. The Health Information System (HIS) landscape in India, unfortunately, is highly fragmented and operates in silos. As a result, data-based health policy and program development has become tedious. Interestingly, the draft new national health policy1 of India envisions to expand universal health coverage, and strengthen health information systems for effective monitoring and assessment of policy implementation. In order to effectively meet diverse data needs of various stakeholders, accurate and timely information exchange among information systems becomes a pre-requisite. To facilitate information exchange among different levels of health system an integrated health information architecture is required. The new health policy aims to develop a health information architecture to drive evidence-based monitoring, evaluation and quality improvement efforts at all the levels of healthcare system1. In the backdrop of the health policy mandate and lack of pertinent knowledge and in-country experience, conducting a research study on health information architecture for improved policy decision making is a timely and useful exercise. For the purpose of this research study the Indian state of Bihar, one of the poorest states in the country, was selected as a case. It is a high priority state for international donors like DfID and the Bill and Melinda Gates Foundation that are implementing innovative health IT interventions like mobile Kunji and mobile academy2.

Research Methods
The objective of this research study was to analyze the current state level health information system landscape in Bihar and then suggest an integrated, but federated, Health Information Architecture (HIA) that will encourage information system innovations at the district and sub-district level while meeting the data and information needs of state level health policy makers. Besides, such an architecture will enable both vertical and horizontal scalability. Two principal research techniques namely secondary literature review and primary data collection were used in this study. The literature search was conducted in two scientific databases namely PubMed and WebofScience. The primary data collection involved eight key informant interviews in Bihar.

Results and Conclusions
The research findings highlight the fragmented HIS landscape and discuss the a) healthcare provider landscape, type of clinical data collected and gaps in clinical data, b) customer’s socio-economic and demographic profile, access to health care services, type of clinical data and interaction with the providers, c) key drivers and motivators for the policy makers and politicians, data collection and analysis, use of data and related decisions, health information technology infrastructure, human resources, and regulations. Based on these findings, a federated HIA model is proposed that can serve information needs of both healthcare providers and public health leaders. Drawing from the global experiences, especially the health information exchange experience in the United States, the final section of the paper describes the factors that are most likely to influence implementation and sustainability of the federated HIA model in a low resource setting.

Archetype Based Nationwide Electronic Health Record Development in Japan

Naoto Kume, Ph.D1, Shinji Kobayashi, M.D.1, 
Kenji Araki, M.D.,Ph.D2, Satoshi Inoue3, Hiroyuki Yoshihara, M.D.,Ph.D2 
1EHR Research Unit, Kyoto University, Kyoto, Japan; 
2Miyazaki University Hospital, Miyazaki, Japan; 
3Japan Medical Network Association, Tokyo, Japan

Introduction

Successful installation of electronic health record (EHR) relies on government initiative. However, public sector does not have affordance to develop and sustain electronic health record as a lifelong record repository in Japan. Billions of subsidies are invested to establish domain specific clinical data repository in the last two decades. Even though, EHRs are not promoted except for a few regions. New government policy, control of increasing medical expense and international competitiveness of medical research, leads the direction that secondary use of medical data should be promoted. Now is an occasion that an update of Personal Information Protection Law and a new national identification number law are approved in the Japanese National Diet. In these circumstances, the authors develop an EHR system and management organizations, by renovation of conventional EHR system under operation for the last decade.

Purpose

The authors run EHRs in Kyoto and Miyazaki region last 15 years using an open source iDolphin, which is implemented by nonprofit organization Japan Medical Network Association (JMNA). This study aims to update iDolphin from scratch based on ISO 13606 Archetype standard, instead of iDolphin original standard medical markup language (MML), which is defined by Medical eXtensible Markup Language Consortium. Also, establishment of two types of management companies for data collection and secondary use are proposed.

Methods

The authors propose a medical information circulation model by establishing EHR cloud system and secondary use systems. Because unification of several standards requires continuous struggles, the authors allow multiple standards for data exchange. Internal database of the proposed system, which is established in a cloud data center, is designed to store the data by ISO 13606 Archetype standard. For instance, EHR systems are implemented by OpenEHR, which is an extension of ISO 13606 Archetypes. In the same way, to optimize Archetypes for Japanese localization, MML is decomposed and reassembled by OpenEHR Archetypes. For example, Archetypes originated from MML are defined for vital sign, prescription and so on. The proposed EHR cloud system, so called global Dolphin, and secondary use database are separately installed and managed by different organization because of compliance with privacy policy. Secondary use contains for clinical support use, patient-informed use, and research use. The secondary use sector gains profit from users so that the profit follows EHR cloud system sustainability. Primary target of data collection is text data; laboratory test, prescription, insurance claim, and some reports such as discharge summary.

Results

This project is funded by the Japanese Cabinet next generation medical ICT council. Data source facilities, including university hospital, public hospital, health examination center, laboratory test center and dispensing pharmacy, have different policy to connect EHR. Some facilities fully agree with the concept. Another require direct profit before connecting EHR, even though it cannot be expected until secondary use database is completely operational. The others emphasize security risk of unexpected information disclosure and do not participate.

Conclusion

Nationwide EHR is desired from patients, clinical use, and research especially for drug manufacture. Japanese government promotes to establish use cases of collected medical data. The authors are under development of nationwide EHR based on an international standard Archetypes. As medical and healthcare organizations' policies have to be paid serious attention, the proposed model is proceeded proof-of-concept with early collaborative organizations.
Integrating Usability Engineering into Undergraduate and Graduate Health Informatics Curricula

Andre W. Kushniruk, MSc, PhD, FACMI, Elizabeth M. Borycki, RN, PhD

1University of Victoria, Victoria, British Columbia, Canada

Abstract

Usability is a major issue in the successful design and implementation of health information systems. However, practical training in usability engineering methods has been limited in health, medical and nursing informatics programs. At the School of Health Information Science at the University of Victoria, an approach known as rapid usability engineering has been applied in a wide range of health informatics projects and teaching contexts. The poster describes how the approach has been applied within our curricula and in work post-graduation.

Introduction

The success of healthcare information technology (HIT) depends on the usability of that technology. However, there are many reports of systems failing due to poor usability. It is clear that there are gaps in the education of HIT professionals about usability. At the University of Victoria’s School of Health Information Science we have been working to address this knowledge gap by introducing practical approaches to usability engineering within our undergraduate and graduate curricula. The approach taken has been based on development of methods that we have designed – namely an approach we have termed “low-cost rapid usability engineering” 1. The approach takes a pragmatic view of usability engineering in HIT that can be conducted in-situ, at low cost and rapidly in real clinical settings. In this poster we outline our approach to bringing usability engineering into health informatics curricula.

Methods

During a major curricula review a qualitative analysis was conducted to determine where usability engineering could be incorporated in our curricula. Based on interviews and surveys with key stakeholders it was determined that a third year undergraduate course entitled “Human Aspects of Healthcare Information Systems” would be an ideal insertion point to embed 4 month-long small group projects that required students to apply the usability methods. At the graduate level the methods were embedded in a course on human factors for HIT. Information about the positions our students took during co-operative educational experiences and upon graduation was also analyzed.

Results

465 undergraduate and 143 graduate students in our health informatics programs received training in the application of rapid low-cost usability engineering methods since 2008. The main pedagogical approach to their training has been through project work requiring application of low-cost rapid usability engineering on real world projects. This has lead to application of their skills in a variety of co-operative educational experiences (where our students have introduced the methods to their employers) and the new application of the methods in key organizations where students have taken up key positions upon graduation (including in the government, industry and hospital sectors). Students perceived the course as being useful and this increased over time. Interviews with graduates indicated over 50% applied their learning in a variety of roles (e.g. as system analysts, managers), while a growing number were working as human factors specialists in healthcare (e.g. working overseeing usability testing of EHR deployments).

Conclusion and Discussion

In our work we have attempted to integrate competencies related to usability engineering into undergraduate as well as graduate health informatics programs. The approach described has worked to create a cadre of health informatics professionals who have not only gained understanding of the importance of usability, but who have hands-on practical experience in applying usability engineering methods and who have worked in transferring that knowledge and skill in a range of sectors. In addition, the topics are evolving to include usability of mobile and other devices.

Background

Intensive Care Units (ICU) are stressful environments for patients and their family members. Potentially life changing information inundates patients and their family members, who often suffer from Post Traumatic Stress Disorder (PTSD) after discharge. Although the reasons for distress in the ICU are likely multifactorial, in several studies family members of ICU patients reported information needs and decision related stress as important contributing factors (e.g., McKiernan & McCarthy, 2010; Azoulay et al., 2005; Botti, Orfali, & Iyengar, 2009). The modality of information delivery could be influenced by the personalities and communication preferences of the family members of ICU patients. People who want to use computer tablets may have different personalities and communication preferences.

Methods

Participants from the Osher Institute for Lifelong Learning in Salt Lake City and college students from the University of Utah were asked about their preference for using a tablet through the administration of the following: 1) a modified version of the Degner Control Preferences Scale (CPS) (Degner, Sloan, & Venkatesh, 1997) 2) The abbreviated Big Five Inventory (BFI-10). The CPS was used to measure preference for engaging in shared decision making. Participants indicated their preference from most preferred to least preferred answering, “how you would prefer to make decisions with your doctor” with the mid-point of the scale representing an equally shared option. The BFI-10 was used to assess neuroticism (mean of responses to the following statements: “I see myself as someone who is relaxed, handles stress well.” [reverse scored] and “I see myself as someone who gets nervous easily.”). In other samples, the reliability and validity were shown to be good (Rammstedt & John, 2007).

Results

Participants’ (N=359) data were analyzed. One outcome measured correlations between “tablet use” (higher numbers mean more willing to use a tablet to obtain information) and the following covariates: age, sex, preference to utilize the Internet when seeking medical information, the BFI personality variable—neuroticism, and a preference for shared decision making using the CPS. Using the Internet to obtain medical information is positively correlated with “tablet use” (r = 0.11, p < 0.05); neuroticism is negatively correlated with “tablet use” (r = -0.11, p < 0.05); and CPS is negatively correlated with “tablet use” (r = -0.12, p < 0.05). This implies that a participant with relatively high neuroticism and higher scores (signifying a more deferential preference for participation in shared decision making) on the CPS is less willing to use a tablet. A multivariate linear regression analysis showed a preference for more deferential decision making (β = -0.11, p < 0.05) and researching health information using the internet (β = 0.30, p < 0.05) outperformed the other variables in predicting preference for tablet use, indicating that information preferences are more important than neuroticism, age, or sex (r² (adj) = 0.03; F (df, df) = 3.343(5,342); p < 0.01).

Conclusion

Study participants report a willingness to use a computer tablet. Tablet users have a preference for more autonomous shared decision making, and researching health information using the internet. These findings would indicate that an ICU transitioning towards a patient-centered model should have tablets available for patients and families to allow for greater access to information and the internet. These information tools could assist patients and families to explore care options and make treatment decisions with their clinical team.
Evaluation of Simulated Computerized Provider Order Entry Rules Toward Evidence Based Blood Utilization

Jaie Lavoie, PharmD¹, William V Miller, MD², Min Kim, PhD¹,³
¹Department of Health Management and Informatics, University of Missouri, Columbia, MO; ²Department of Pathology, University of Missouri School of Medicine, Columbia MO; ³Informatics Institute, University of Missouri, Columbia, MO

Abstract
We evaluated how additional alert override steps affect evidence based and non-evidence based transfusion ordering behaviors. Nine inpatient physicians participated in a newly created simulated ordering environment, where five providers received a typical scenario for overutilization and four providers received a scenario where a rule that only considers hemoglobin would discourage an evidence based transfusion. The new order rules prevented 100% of inappropriate orders while allowing 75% of appropriate orders to override an incorrect alert.

Introduction
Studies suggest that as much as two thirds of red cell orders are non-compliant with evidence based recommendations. CPOE rules based on patient hemoglobin levels have been a proposed solution to this problem. However, it is unclear how difficult to override a rule should be in order to be effective at preventing orders with no evidenced based indication and what the potential impacts of these rules are on necessary transfusion ordering. The purpose of this pilot study is to evaluate the effect of additional alert override steps on evidence based and non-evidence based transfusion ordering behaviors.

Methods
A web based application was developed to simulate order entry. The application presented two medical case vignettes and then simulated an interactive order entry process with a triggered alert. The alert rules were solely based off the most recent hemoglobin value with a cut point of 8 mg/dl to determine if an order was in compliance with evidence based practice. Attempting to override the alert required providers to enter free text justifications with at least 150 characters to continue. The two clinical vignettes designed were: (1) an overutilization vignette having characteristics of a case that in practice would commonly receive a transfusion, however not have an evidence based indication, and (2) a non-hemoglobin indication vignette with an evidence based indication for a transfusion that is not likely to be detected by automated rule based systems. In this manner the former would be more likely to prompt a non-evidence based order and desired alert while the latter would be more likely to elicit an evidenced based order but an undesirable alert. Simulation data, including orders, number of alerts generated, attempts, justifications, and success at overriding an alert were recorded into a relational database.

Results
Nine subjects were recruited from a pool of eighty seven inpatient physicians who were eligible to order a blood transfusion at the university health system. Five providers were randomized to the overutilization vignette and four to the non-hemoglobin indication vignette. Three out of five providers (60%) in the overutilization vignette chose to order a blood transfusion and were given an alert that the order was not recommended based on the hemoglobin level. One provider canceled the order immediately while the other two providers attempted to override the alert. Upon being presented with the free text justification box that could not be left blank, however, the two providers who initially attempted to override the alert withdrew their orders. On the other hand, all four providers who received the non-hemoglobin indication vignette, placed an order for a transfusion. These four providers were given an alert that the hemoglobin value did not indicate a transfusion as the indication was not based on hemoglobin but instead a free text finding in the note not considered by the rule. While three of four providers (75%) successfully wrote an appropriate justification and overrode the alert, one chose to cancel the order after unsuccessfully attempting to submit a justification below the character length requirement.

Conclusions
While data collection is still in progress, preliminary results suggest that rule based alerts on patient hemoglobin can be highly effective in preventing unnecessary blood transfusion orders especially when they require an additional evidence-based review process. For example, two out of three non-evidence based orders attempted to override, which had the process been as simple as a single click would have allowed these orders to continue. While preventing unnecessary orders is critical, care must be taken to not prevent orders indicated by non-discrete clinical findings or where the hemoglobin is rapidly trending down / outdated. Acknowledging the limitation of the current alerts used in CPOE systems, a balance should be made between the ability to deter unnecessary orders and the ease of overriding erroneous alerts. This study was conducted in a non-clinical setting in a single center with a small sample which warrants large study in a real clinical setting. For example, higher levels of stress/alert fatigue may alter provider behavior in a real clinical setting, which may not be observed in the study. Despite these limitations, the preliminary results are encouraging and merit continued study towards the more effective means of leveraging CPOE systems to help optimize effective blood management in the health system.
Semantic and Interactive Timeline for Patient Data Visualization

T. Ledieu1,2, P. Van Hille1,2,3, G. Bouzillé,MD1,2,3, E. Renault1,2, M. Cuggia,MD,PhD1,2,3
1INSERM, U1099, Rennes, F-35000, France; 2Université de Rennes 1, LTSI, Rennes, F-35000, France; 3CHU Rennes, Centre d’Investigation Clinique, Unité Fouilles de Données, Rennes, F-35000, France

Introduction
Considering the multiplication of sources of health care information, providing to physicians effective and integrative tools to easily visualize the medical history of the patient is crucial. A timeline is a chronological representation of a list of events which may use different time and data scales. In this work, we introduce new advanced features into a timeline framework for patient data visualization, using interactive GUI, semantic data aggregation and time navigation functionalities. The purpose of this visualization tool is to offer a generic and synthetic display of the medical data which could be adapted according to a specific medical problem or the physician specialty.

Methods
The prototype was developed from an existing timeline component based on D3 Framework1. This prototype was designed as a weakly coupled component in order to be integrated to different data repositories such as EHR or Clinical Data Warehouses. The patient dataset used for the development includes free text, structured and coded data with different international and French terminologies (e.g. ICD-10 for diagnosis, ATC for drugs, CCAM for procedure codes), and numerical data (results lab). A semantic aggregation method uses hierarchical properties of terminologies. Domain and visualization ontologies were developed and combined with a set of rules to dynamically filter the patient dataset and generate adapted views according to the physician specialty into the timeline.

Results
The user can navigate in time using a temporal window and choose the time scale in those synchronized timelines. The user can search a medical concept in a free-text zone, and select it to display the data into the timeline. This data is shown by colored dots for punctual events or colored rectangle for a period. The user can aggregate/disintegrate the data element under the different classification systems. He is also able to read textual documents and search terms in full text. A specific displayed have been developed for one medical field: rheumatology. The rheumatology timeline shows the evolution of patient’s joints status on a diagram. In order to make a clearer understanding display for a clinician, we have integrated an icon-based language (VCM language²) mapped on the ICD-10 classification to display diagnosis in the timeline.

Conclusion
Timeline representation helps to integrate multi domains patient information over time. Our prototype is used by both physicians and data scientists to better analyze health care events in several dimensions. This work is in progress: we plan to represent textual data through temporal dynamic semantic clouds. Conceptual navigation feature will be extended to use other kind of semantic relationships (e.g. part_of, has_finding). Aggregation visualization method will take into account temporal dimension. A search engine will be developed for enable the composition of a customized timeline by users (e.g. timeline for a specific medical problem or several timelines for comparison of patient care trajectories).

The Master Data Element Visualization: A Consolidated View of the EHR Data at Intermountain Healthcare

Jaehoon Lee, PhD1, Farrant H. Sakaguchi, MD1, Justin Mundt, MS1, Bart B. Dodds1
Gary D. Bishop1, Nicole K. Hobbs, PhD1, Katherina C. Holzhauser1, Stanley M. Huff, MD12
1Intermountain Healthcare, Murray, UT; 2University of Utah, Salt Lake City, UT

Abstract

The master data element visualization provides navigation and interactive visualizations of the electronic health record (EHR) data at Intermountain Healthcare. The key features are 1) a sunburst tree visualization to represent classes of hierarchies, 2) data visualization for volume and distribution of the EHR data, and 3) a search function for concepts and codes. The tool was implemented internally for clinical researchers and demonstrated its usability.

Background

Intermountain Healthcare is a non-profit healthcare organization that has collected 20 years of clinical data through its EHR, and visualization has been used in clinical applications to provide an intuitive understanding of the data. However we have several challenges to 1) handle the size, complexity, and contextual understanding of huge EHR data, 2) develop normalize scheme for aggregated data, and 3) present a large set of information in a single screen.

Method

We developed the Master Data Element visualization: a web-based data navigation and visualization tool based on d3.js1. The tool deals with essential data elements of the EHR such as patient demographics, encounters, vitals and labs, diagnoses, procedures, and medications. To provide visualization of large population in a timely manner, we developed an aggregated data model and cached the data of 4,676,644 patients from 1994 to 2015. The key features of the tool are 1) a sunburst tree visualization to provide a high-level overview and drill-down of Intermountain’s data hierarchies (Figure 1 Left), 2) a search function for a concept or a code in the hierarchies (Figure 1 Left), and 3) 16 data visualizations using four types of charts (line chart, bar chart, box plot, and histogram) to present volume of codes, number of patients, and statistical distribution of numeric values (Figure 1 Right).

Figure 1 Left) By clicking a slice of the sunburst tree users can drill down the hierarchies. Users can search a concept or a code on the right panel and each search result provides a hyperlink (red) to data visualization of the code. Right) At a selected category (e.g. vital sign) of the hierarchies, the right panel shows available data visualization; each visualization provides drill down at code level (e.g. histogram of respiratory rate of patients by sex, age group).

The tool was implemented within Intermountain’s firewall to be used for internal clinical research and demonstrated its usability, computational efficiency, and feasibility to address the problems stated above to some extent. However the tool currently covers only small part of Intermountain’s EHR and it taxonomy is limited to present complex hierarchies of the EHR data. Our future work is to adopt knowledge bases and standard terminologies from Intermountain’s healthcare data dictionary to enrich the hierarchies and the search functionalities.

Applying an instant messaging system at the hospital to support TRM

Ying-Li Lee¹,², Tsai-Feng Chien¹, Hsiu-Chin Chen¹
¹Department of Nursing, Chi Mei Medical Center, Tainan, Taiwan; ²Institute of Biomedical Informatics, National Yang Ming University, Taipei, Taiwan

Abstract

Effective communication among the healthcare team is needed to facilitate team resource management (TRM). We aimed to develop an instant messaging system, Link to Team (L2T), embedded in the original hospital information system to improve the communication and coordination among all members of the healthcare team. Based on the idea of patient-centered and workflow-driven, we used the rapid application development model (RAD) to develop an easy-to-use and user satisfied instant message system.

Introduction

Nurses spent 19-24% of their time in professional communication.¹ They often connect and communicate with different members of the healthcare team by telephone. However, the telephone communication might interrupt the current work of the receivers. The misunderstanding of messages could happen during message transcribing or remembering incorrectly. We developed an instant messaging system which was nicknamed Link to Team (L2T) system. The purpose of our project was to support the healthcare team resource management and improve the communication and coordination among all members of the healthcare team.

Method

We conducted the focus group interviews, the healthcare teams’ workflow surveys and the workflows simplifications before designing the system. According the text message proposed by users themselves, we set up various message templates in each communication scenario. The rapid application development model (RAD) was applied to software development. After several iterative modifications, the system was implemented officially. After 3 months of implementation, we conducted interviews, a system operation testing and a satisfaction survey for the users to evaluate the preliminary outcome. After 6 months of implementation, we analyzed the usage of the system.

Result

In preliminary outcome evaluation, we interviewed 15 nurses. The respondents indicated that they have replaced most telephone communication by the L2T system. It’s very convenient to transmit a message to a number of recipients simultaneously. It saved lots of time in team members connecting. Besides, the content of the text messages was more correct and clear. Users can also query history information in the system to avoid forgetting messages. We also randomly sampled 29 nurses and conducted a questionnaire survey for primary users’ experience. Most users were satisfied with the color scheme and the design of the interface, easy to learn and easy to use the system. 86.2% users were familiar with the system function. After 6 months of implementation, we analyzed the history records of the system from January 1 to January 31, 2015. The total number of records was 20,781. 51.21% messages were related to notifying another nursing station about patient transfer information. 31.32% messages were communicated between the ward and operating room about the patient surgery preparation. 13.38% were used for communication between colleagues of the same nursing station. The outpatient clinic nursing staffs have the highest utilization rate in requesting support. 68.42% of messages were received and processed within three minutes.

Conclusion

This project was satisfied the users’ expectation in rapidly, easily and correctly operative. Meanwhile, it also improved the timeliness and coordination between the healthcare team. The L2T system was designed as a communication tool to meet the workflows of various departments. Next, we would like to integrate the workflows of those departments that have not been included in this project. It is expected that wider adoption of the current L2T system will help to improve clinical and administrative work processes in the future.

Quantifying the Complexity of Discharge Planning in the Inpatient Cardiology Unit

Young Ji Lee, PhD, RN¹, Corrine Benacka, RN, CCRN², Matthew B. Carson, PhD¹, Gayle Kricke, MSW¹; Preeti Kansal, MD², Nicholas Soulakis, PhD¹

¹Northwestern University, Chicago, IL; ²Northwestern Memorial Hospital, Chicago, IL

Introduction: Well-organized, multidisciplinary discharge planning bridges the gap between home and hospital to reduce readmission rate²-³. Patients should have the option to be active participants in the process; however, they are often confused whom they can ask for help due to the complexity of the process¹. A study describing discharge planning found patients typically meet 3 to 7 types of healthcare provider; however, to our knowledge, no study has quantified the actual number of providers involved in discharge planning². Electronic Health Records (EHR) has become an essential research resource for exploring the structure of healthcare providers³. Thus, the goal of this study is to understand the complexity of discharge planning in an inpatient cardiology unit through EHR by quantifying the total number of providers and the number of new providers per day involved in discharge planning activities.

Methods: Using the Northwestern Medicine Enterprise Data Warehouse (NM EDW), we identified records of patients with heart failure (HF) who were admitted to Northwestern Memorial Hospital’s cardiology unit and discharged between 12/1/14 and 12/31/14. All HF-associated providers and discharge-planning activities were also extracted. “Discharge planning activities” were determined and validated by a nurse care coordinator and the director of the cardiology unit. We defined “Providers” as healthcare providers and non-clinic personnel who performed discharge-planning activities. “New providers” were defined as a provider not previously seen at the point of the activity. Terminologies followed the Cerner system. The analysis was performed using custom scripts written in the R program.

Results: We identified 42 patients, 99 providers and 839 individual discharge-planning activities. Sixteen types of providers; 19% of providers were ‘Patient care staff nurses’. Thirty discharge-planning activities were identified within the timeline. The range of patients’ length of stay was between 1 to 38 days (median=6). All 42 patients started their discharge planning at the first day of their admission, and they met 7 providers for their discharge planning on average. We found out that patients met most discharge-related providers near the end of their hospital stay (Figure 1). Interactions between patients and providers are visualized in Figure 2.

Conclusion: We found that more types of providers are involved in discharge planning than stated in previous literature. Also, the study showed that the number of providers accelerates towards the end of an inpatient stay. Further study with a larger sample is needed to understand how complexity of care affects health outcomes.

Design of a Knowledge Exchange for Community Health Workers

Harold P. Lehmann, MD PhD, M. Christopher Gibbons, MD MPH, Richard Singerman PhD, Steven King, Joe Warren MS, John May MS MBA, Johns Hopkins School of Medicine, Baltimore, MD; Johns Hopkins School of Public Health, Baltimore, MD
TrustNetMD, Inc.

Community Health Workers (CHWs), a mainstay of healthcare in low- and middle-income countries\(^1\) are poised to become an increasingly important part of the US healthcare landscape\(^2,3\): They engage patient in the community, they are less costly than licensed healthcare providers, and they are effective.\(^4\) Their information needs have not been supported formally so few information resources have been provided to them that represent evidence related to those needs. Those that have focused on this issues have reported positive results using rich media to support the workflow of our CHWs.\(^5,7\)

We have created such a resource (CHWresources.org) based on the following principles: (1) CHW are experts in being CHWs; (2) CHWs have specific tasks that fall into specific classes; (3) Resources for CHWs should be tailored to those tasks

To this end, we conducted focus groups (IRB # NA_00085655) of 36 CHWs in Baltimore, Connecticut, and Brooklyn, NY to create a taxonomy of tasks falling into 4 classes: Assess client needs; Connect clients to community resources; Overcome family barriers; Attend to personal professional needs. Resources fall into categories as well: Evidence-based published articles and guidelines; other authoritative information (published texts, web sites, videos); community-based resources; and knowledge exchanged among CHWs. These classes have been validated by several CHW groups.

A knowledge exchange (Kx), also called Web 2.0 with a learning social network, enables CHWs to ask questions of each other; to rate resources or to vote questions and answers “up” or down. These features enable crowdsourcing and the emergence of expertise from among the group:

- The four task classes are denoted by color-consistent buttons and tabs.
- Clicking on either brings the user to a search page enabling typing, voicing, or selecting tags, coded according to the task classes.
- The search-results page enables rating, voting, commenting, questioning, answering, and sharing of new resources.
- The resources database comprises hundreds of authoritative and community resources.

The Web 2.0 site can be contrasted with a Web 1.0 version, which offers the information resources, but not the interaction. While it would seem obvious that a Kx is desirable, it is not clear whether the added task burden and complexity is worth the information gained. For this purpose, we are conducting a cluster-randomized trial of the Web 1.0 vs Web 2.0 versions in cities across the country (IRB #IRB00049686).

Theme: Interactive Systems Track: Applications of Informatics
Decision Factors Influencing the Selection of a “Hand-off” Model Versus a “Hold-on” Model for Telehealth Service Lines

Cynthia LeRouge, PhD¹, Suzanne Wood, PhD¹, Ryan Sterling, MPH/MSW¹
¹University of Washington, Seattle, WA

Abstract

The need for robust and effective telehealth programs (often composed of multiple service lines) has never been greater, leaving healthcare organizations clamoring to develop delivery systems that result in effective workflow and desired outcomes. Examined are two distinct management approaches to telehealth service lines service lines - “hand-off” versus “hold-on” models, Results specify factors underlying model selection and the role of telehealth departments in facilitating effective workflows to support successful implementation and sustainable operations.

Introduction

Given the increasing number of telehealth programs, organizational structures (e.g., departments) with dedicated leaders to manage multiple service lines are increasingly common. Selecting telemedicine management models to drive appropriate workflow can prove challenging for telehealth programs due to wide variation in care settings, provider types, and service lines across which programs are implemented. Disruptions to clinical workflow can impede the success of health information technologies. Unfortunately, research that describes, analyzes, and discusses the impact of alternative management models on the implementation, adoption, and on-going operations of telehealth service lines is scarce. This study explores two distinct management models deployed for separate service lines: a decentralized “hand-off” model and a centralized “hold-on” model, respectively (see Table 1). Study objectives are to identify factors for selecting each mode, and to provide insight into the role of the telemedicine department in facilitating implementation and operational workflow under each model.

Methods

A mixed methods approach was used to perform a comparative longitudinal case study of two telemedicine programs, TeleHepatology and TeleStroke, operated at a not-for-profit health network under a single telehealth manager. Data sources included stakeholder surveys, archived program documents, clinical program results, and transcripts from program management meetings. These rich data sources enabled researchers to triangulate findings and enhance research validity and reliability. All interviews, meetings, and discussions during site visits were audiotaped, transcribed, and reviewed for errors. Qualitative analyses were conducted with NVivo © and Dedoose © using guiding principles from Lee and Baskerville (2003) to transform data into themes and develop insights1.

Results

Preliminary results identify workflow factors specific to each individual management approach as well as common factors that should be prioritized across both models. Factors unique to the “hand-off” approach stress stakeholder engagement, mentorship of service unit and telehealth managers, as well as information sharing and education. Factors unique to the “hold-on” approach stress appropriate pacing of program growth (including human resources), development of clinical champions, and assembling expertise from within when needed. Common success factors in both models stress the development of standardized, evidence-based best practices and progress assessment.

Conclusion

Results point to certain key decision factors that can guide healthcare organizations in choosing telehealth management models to support implementation and operational workflow. Specifically, variations in the capacity of service lines, technical support needs, and value proposition alignment are highly influential to decision-making.

Drug-Disease Associations in Guidelines, Drug Labels, and Practice

Tiffany I. Leung, MD, MPH\textsuperscript{1}, Michel Dumontier, PhD\textsuperscript{2}

\textsuperscript{1}Division of General Medical Disciplines, Stanford University, Palo Alto, CA; \textsuperscript{2}Stanford Center for Biomedical Informatics Research, Stanford University, Palo Alto, CA

Introduction
Clinical practice guidelines (CPGs) recommend pharmacologic treatments for certain clinical conditions based on systematic reviews of medical literature, and drugs' structured product labels (SPLs) provide drug profiles, including treatment indications, approved by the FDA after review of clinical trial evidence. Both resources are intended to promote evidence-based medical practices. Practice patterns should also match guideline-recommended and FDA-approved prescribing. For example, denosumab, a monoclonal antibody that inhibits bone resorption, has FDA-approved indications for postmenopausal women with osteoporosis and for increasing bone mass in men with osteoporosis. Conversely, osteoporosis guidelines typically recommend denosumab as a pharmacologic treatment option for the condition, but other disease guidelines do not recommend denosumab as a treatment alternative. In this instance, the CPG-recommended pharmacologic therapy and the SPL treatment indication match, and electronic health record (EHR) data should reflect a prescription for denosumab only for a patient who has diagnosed osteoporosis. In this study, we use text mining methods to determine how well drug product labels' treatment indications and prescribing practices for 15 chronic conditions match CPG-recommended pharmacologic treatment.

Methods
We focused on 15 common chronic conditions among Medicare beneficiaries, defined by 448 ICD-9 codes. In order to assess how well-matched drug-disease associations were across CPGs, SPLs, and practice data, we built drug-disease associations from SPLs using a computer-readable side effect resource (SIDER), outpatient prescribing data for patients with any of the ICD-9 codes corresponding to the 15 chronic conditions on their problem lists using EHR data from the Stanford Translational Research Integrated Data Environment (STRIDE), and CPG text from 494 relevant guidelines from the National Guideline Clearinghouse. For CPGs, we applied a text-mining algorithm similar to that used in a previous study to extract chronic disease mentions;\textsuperscript{(1)} however, we used this algorithm to identify drug mentions in CPG text by exactly matching a list of drug names. We used DrugBank as an encyclopedia to identify a list of more than 11,609 drug names, their synonyms, and drug categories, which we subsequently enhanced with 420 additional terms using four ontologies (SNOMEDCT, NCIT, NDF-RT, CHEBI) from Bioportal at Stanford University’s National Center for Biomedical Ontology, to create a list of 12,030 drug names. We determined the frequency of matches and mismatches of drug-disease pairs among CPGs, SPLs, and practice data.

Results
Our results yielded 1,999 drug-disease associations from 494 relevant CPGs, and 533 drug-disease associations from SPLs. Of these, there were 240 drug-disease association matches between the two data sources, representing only 12% of all associations in CPGs and 45% of all associations in SPLs. The frequency of drug-disease associations in CPGs, SPLs, or both varies depending on which chronic disease guidelines are of interest. Initial evaluation of this method for 10 heart failure guidelines for drug names alone demonstrated precision 0.98, recall 0.77, and F-measure 0.86; for drug names plus drug class names, precision was 1.00, recall 0.19, and F-measure 0.32. In EHR data, 13,689 drug-disease associations were identified and there were 1,193 matches out of the 1,999 CPG drug-disease associations. This represents 59.7% of all associations in CPGs and 8.7% of all associations in EHR data.

Conclusion
Our preliminary results suggest that there is a mismatch between guideline-recommended pharmacologic therapies and drug product label indications, suggesting potentially conflicting prescribing guidance from CPGs and SPLs. Further investigation of the identified mismatches may guide harmonization of clinical knowledge sources. The higher number of matches in EHR data compared to CPGs suggests that prescribing practices match guideline recommendations better. Further improvement of the text mining methods, particularly leveraging the taxonomic organization of drug ontologies to improve recall, may address limitations of our approach to drug-disease associations identified in CPGs and SPLs.

Developing an Electronic Survey to Capture Current State of Acute Care Patient Portals to Inform Best Practices and Future Directions

Waiyin Leung, MS1, Sarah Collins, RN, PhD1,2,3* and Anuj K Dalal, MD1,2,3*

1Brigham and Women’s Hospital, Boston, MA, 2Partners HealthCare System, Boston, MA, 3Harvard Medical School, Boston, MA *Co-PI

Abstract: To date, patient portal research has been in the ambulatory settings. There are limited data on the use of patient portals in acute care settings. Using an iterative process, we developed an electronic survey that aims to capture critical data on the current state of acute care patient portals at four academic medical centers in order to identify new directions for development and investigation. We describe the survey development process and the resulting survey.

Introduction: Meaningful use requirements for patient engagement and increasing patient expectations for online access to health data call for the need for expanding use of patient portals. Though evidence-based practices for patient portals are well in ambulatory settings, these are lacking in the acute care setting. Consequently, many patients and their caregivers generally do not access personalized health information via patient portals in hospital settings, although use could lead to higher patient satisfaction and better health outcomes.1 Engaging hospitalized patients through the use of health information technology in the acute care setting is an area of active innovation and development. More research regarding how institutions design, develop, and implement acute care patient portals is necessary to inform best practices. A thorough understanding of currently available infrastructure across institutions is required. Specifically, investigation should address portal content and security, policies regarding data access and availability, and management. The purpose of this study is to describe the process by which we developed an electronic survey to 1) identify key features of an acute care patient portal that are common across sites, 2) recognize common operational and implementation challenges, and 3) define best practices for portal design, configuration, and use for future investigation and innovation.

Methods: We developed a survey using REDCAP2 (Figure 1), an electronic data capture tool hosted at Partners Healthcare Systems. Questions were modified based on a survey instrument that assessed policies and current state of ambulatory patient portal.3 We included questions regarding both inpatient and ambulatory patient portals given the growing interest in developing enterprise-wide patient portals that provide a unified patient-centered experience for patients and caregivers across all settings. We used a participatory process with input from collaborators at four academic medical centers to iteratively refine the survey questions.

Results: Because study investigators were concerned that the survey did not consider institutions that do not have an existing acute care patient portal, we included a question to assess whether an individual institution had an existing acute care patient portal; if not, they were asked if they were planning to acquire, develop, and implement one in the future, and if so, they would provide insights on their plan. The survey used branching logic and multiple formats including yes/no questions and free text boxes to capture quantitative as well as qualitative data, respectively. The final survey asked questions regarding patient portal leadership, access for patients and healthcare proxies, usage statistics, key features and clinical data available for access by patients, specific policies in place, challenges encountered/anticipated during development and implementation, and visions and goals for improvement or development.

Conclusion: We developed an electronic survey that captures a wide range of details about a healthcare institution’s strategy for future acute care patient portal use in order to identify common practices across institutions. The survey addresses a critical need for establishing best practices and future direction for acute care patient portal development, implementation, and operation to increase patient engagement during hospitalization. Quantitative survey data can be analyzed using SPSS for descriptive statistics and qualitative data using NVivo software for themes. It is encouraged that such surveys are conducted with other institutions to support this area of research. Results from analyzed surveys will be used to build a conceptual model for acute care patient portals and make recommendations for future investigation.

Acknowledgments: This BWH Libretto Task Force is funded by the Libretto Consortium supported by the Gordon and Betty Moore Foundation. We acknowledge the Libretto Task Force team members for their contribution to and feedback for the survey questions.

A Deep Learning Framework for Improving Medical Information Retrieval
Ding-Cheng Li PhD1, Saeed Mehrabi, PhD1, Yue Yu, MS1,2, Honghua Liu, PhD1
1Mayo Clinic, Rochester, MN; 2Jilin University, Changchun, China

Background and Introduction. Many innovations in language modeling for information retrieval can be considered to combine multiple alternative document representations or “layers” [1]. However, questions incurred are what layers should be included and whether we can find layers which can be general enough to fit all kind of data. One common agreement is that concepts are playing gaining roles in building more advanced language models. Zhu and Carterette represent a document in separate text and concept spaces and then combine them into a statistical language model. Wei and Croft represent a document via latent Dirichlet allocations. Both of them reported higher performances were achieved. Recently, deep learning evolved from traditional neural networks have seen widespread use in natural language processing due to its powerful capacities of catching hidden similarities among words and phrases. However, up to now, no system has been constructed with deep learning for medical information retrieval. In this work, we propose to build a new layer with deep learning in order to empower our existing layered language model, where bag of words, medical concept unique identifiers and dependency relations are integrated.

Methods. Based on previous work, our proposed framework focuses on two steps, associating each word w with a vector representation \( x_w \in \mathbb{R}^d \) and computing distributed representations for each sentence with a dependency-tree recursive neural network (DT-RNN) [2]. Word-embedding is a technique to represent individual words with a vector. As we know, words themselves are often incomplete in meaning and full of ambiguous. They have different meanings under different contexts. Word-embedding overcomes this weakness by making use of the morphological and syntactic knowledge of words in a sentence or a passage or some slides of windows in a context to transform each of them into a rich semantic representation. We employ GloVe (global vectors for word representation) model to implement the word-embedding. These vectors are stored as the columns of a \( d \times V \) dimensional word embedding matrix \( W_e \), where \( V \) is the size of the vocabulary and \( d \) is the length of the dependency tree. DT-RNN then takes dependency parse trees (obtained with Mayo eTAKES pipeline) of both queries and the medical records as input.

Each node \( n \) in the parse tree for a particular sentence is associated with a word \( w \), and accordingly a word vector \( x_w \). Unlike in constituent trees, where all words reside at the leaf level, the internal node in the parse tree is a hidden vector, which are associated with words and arcs connecting nodes represent the dependency relations among words. Taking advantages of information of the hidden vector, DT-RNN aims at optimizing the semantic representation of the corresponding words, phrases or sentences. Specifically, it combines the each node’s word vector with its children’s hidden vectors to form \( h_n \). This process continues recursively up to the root of each dependency tree, namely, the whole sentence. The combination takes the sigmoid function as \( f(W_{e} \cdot x_{w} + b + \sum_{k \in K(n)} W_{R(n,k)} \cdot h_{k}) \) where \( W_{e} \) is a \( d \times d \) matrix with each dependency relation \( r \) in our dataset (similarly, the matrix is built with GloVe) and \( R(n,k) \) is the dependency relation between node \( n \) and child node \( k \).

Experimental Setup and Initial Results. Both 2011 TREC-med queries and 2012 TREC-med queries are utilized for the experiments. They are free text of medical records provided by the University of Pittsburgh’s NLP Group. Each patient at the University of Pittsburg has one more medical records associated with him or herself. Each record contains both structured and unstructured data in XML format, with an average length of 423 words. The overall vocabulary size is on the order of \( 10^5 \). The notes were de-identified, so that any protected health information has been replaced with surrogates. In total, there are 95,702 records that correspond to 17,198 visits. Both records include 81 hypothetical queries that might be used to identify participants. Up to now, we have successfully generated vectors for all the vocabularies and algorithms of the second step has been implemented. After we obtain results of this layer, we will integrate the scores into our layered language models with assigned weights (like other layers, the weight parameter \( \lambda \) and the smoothing parameters \( \mu \) are learned with grid search). Then, the MAP performance of retrieval will be reported.

A survey of automated information retrieval for genetic disorder from GeneReviews

Pu Li, MS¹, Qian Zhu, PhD¹

Department of Information Systems, University of Maryland Baltimore County, Baltimore, Maryland, USA

Introduction.
A genetic disorder is an illness caused by one or more abnormalities in the genome, especially a condition that is present from birth (congenital). Most genetic disorders are quite rare and affect one person in every several thousands or millions. That is to say not too much information about the genetic disorder is available for supporting relevant research. In another hand, GeneReviews is expert-authored, peer-reviewed disease descriptions ("chapters") presented in a standardized format and focused on clinically relevant and medically actionable information on the diagnosis, management, and genetic counseling of patients and families with specific inherited conditions. GeneReviews in free text can be browsed and searched via NCBI website, however, no structured electronic version available to be integrated into the clinical decision support systems, especially for the Genetic Testing Ontology (GTO) developed in our previous work¹². In this study, we conducted a survey by applying two widely-used biomedical annotation tools, National Center for Biomedical Ontology (NCBO) annotator and Unified Medical Language System (UMLS) MetaMap to annotate data extracted from 10 GeneReviews chapters. From this preliminary work, we identified gaps between a large volume of genetic information and insufficient capability of processing such information by using current Natural Language Processing (NLP) tools, and propose the extension of these tools to be able to annotate relevant genetic information.

Methods.
10 GeneReviews chapters corresponding to 10 different genetic disorder have been randomly selected and downloaded from NCBI (http://www.ncbi.nlm.nih.gov/books/NBK1116/). Each chapter includes 10 sections, Summary, Diagnosis, Clinical Description, Differential Diagnosis, Management, Genetic Counseling, Resources, Molecular Genetics, References, and Chapter Notes. In this study, we primarily focused on 7 sections, except for Resources, References and Chapter Notes. Each of the selected sections has been programmatically extracted and annotated by NCBO annotator and MetaMap via their APIs. We manually reviewed and evaluated the results to identify the coverage and gaps of these two NLP tools.

Results.
Total 50,687 annotations have been generated by NCBO annotator and 8,479 annotations by MetaMap. We manually reviewed all annotation results comparing to the original chapters, the average accuracy rate is 74.04% for NCBO annotator and 85.23% for MetaMap. Although 8,749 annotations are exactly matched with UMLS concepts with mapping score equaling 1000, there are some unnecessary mappings, such as “treatment”, “syndrome” that were grouped into incorrect mappings.

Discussion.
This is a preliminary work of examining the feasibility of extracting genetic disorder related information by using the current NLP tools being widely used in medical field. The results produced from this survey not only illustrates that the majority of the information, especially for medication, diagnosis relevant information can be annotated with high accuracy, but also guides us to propose extensions of the existing NLP tools to be able to manage genetic information accordingly based on the gaps identified. The majority of missing/incorrect annotations we identified are falling two categories, genomics and numerical values with relevant context, which are both critical information for genetic disease management. For instance, “Each sib of a proband with 3-M syndrome has a 25% chance of being affected, a 50% chance of being an asymptomatic carrier, and a 25% chance of being unaffected and not a carrier.” Such information about the percentage along with relevant context is critical to predict the risk of affecting 3-M syndrome. Thus, either manual annotation or appropriate component development will be the next step to integrate a complete list of annotations from GeneReviews into the GTO to support iGenetics³.

Detecting Mitral Valve Prolapse (MVP) From Heart Sound Recordings

Yihua Li, Dorothy W. Curtis, M.Sc.
Computer Science and Artificial Intelligence Laboratory, MIT, Cambridge, MA

Overview
In this project, we apply machine learning techniques to detect Mitral Valve Prolapse (MVP) from phonocardiogram (PCG) and electrocardiography (EKG) recordings of the heart. After segmenting each recording into individual heart beats, we use Gaussian mixture model to assign the beats into disease and normal clusters based on the presence of murmurs. Features are extracted from this beat level clustering and are used to classify each patient with support vector machine (SVM). We achieve an overall precision rate of 94.7% and recall rate of 88.9% on our dataset. This automatic heart sound analysis is valuable in the diagnosis process and should reduce false positives.

Introduction
MVP is a cardiac disorder characterized by the displacement of an abnormally thickened mitral valve leaflet into the left atrium during systole. During cardiac auscultation, skilled cardiologists detect MVP by the presence of murmurs, high frequency noise-like sounds caused by abnormal blood flow patterns. However, the interpretation of heart sounds is a difficult skill and subject to human auditory limitations. As a result, automatic MVP detection would be very helpful. Previous works focus on the classification of different heart valve diseases by machine learning methods [1]. Here, we focus on the case of MVP and seek to integrate beat level classification into the final decision, considering that not all beats in the recordings of a MVP patient exhibit murmurs.

Dataset Description
The dataset, provided by Massachusetts General Hospital, comes from 43 healthy individuals and 36 MVP patients. For each subject, EKG and PCG were recorded from 1 to 3 different locations of the heart. Each recording is roughly 30 seconds long. We give the recordings the same label as that of each person given by the physician. Half of the data is used as the training set and half as the testing set.

Method
We first carry out classification on the beat level. The PCG recordings are segmented into heart beats through peaks in the EKG recordings. The locations of s1 and s2 are identified as in [2]. We then take the wavelet transform of each beat using a Daubechies wavelet with 2 vanishing moments, and perform a level-8 decomposition of the signal. This wavelet transform allows us to separate murmurs from baseline sounds. For the features, we look at the decomposition of the beat at level 7. Since the disease beats typically have high energy murmurs during the systolic phase, the chosen features are: (1) the energy during systole normalized by the energy during s2 and (2) the location of the peak during systole. With these features, we then soft assign the individual beats from all recordings into disease and normal clusters using Gaussian mixture models. We apply this unsupervised method since only the labels for recordings, not individual beats, are available and a MVP recording could contain normal beats. All the beats from normal recordings and a small subset of manually labeled disease beats are used to initialize the clusters. Next, we classify whether a patient has MVP using SVM. To obtain the features, for each recording we calculate the following: (3) the percentage of disease beats, (4) the posterior probability that a beat belongs to the disease cluster, averaged across all disease beats in that recording. As a patient has multiple recordings, the final features for each patient are the average and the maximum of (3) and (4) across his/her heart sound recordings.

Results
We analyze the data in MATLAB and achieve an overall precision rate of 94.7% and recall rate of 88.9% on our testing set. Our future work is to take into account, during classification, the location where the recording was taken.

Conclusion
We designed a 2-level classification method for automatically detecting MVP from heart sound recordings. The preliminary result on our dataset suggests that our method has the potential of being applied to real-life diagnosis.

Design of a “Synthetic” Data Set for Teaching and Evaluating Analytics Methodology in Accountable Care Organizations

Robert W. Ligon, MS,
University of Texas, Austin, Texas

Abstract

See submission content

Introduction

Accountable Care Organizations (ACOs) were introduced in the Affordable Care Act as a pilot program developed by CMS to pilot shared savings as a model of assuring quality while reducing costs in healthcare delivery. The makeup of these organizations can vary; but they often involve multiple healthcare organizations including physicians, hospitals, clinics, ambulatory surgery centers, laboratories and pharmacies. These distributed data environments create several challenges for ACO data governance.

First is data standardization. Often the participating organizations have different EHR products with different data requirements, data standards and data definitions. Secondly, is the creation of a master patient index to identify patients throughout the continuum of care. Thirdly a centralized system for providing data standardization and preprocessing and finally a system that will allow for analysis of clinical, financial and outcomes data for reporting.

When presented with these challenges many organizations lack sufficient training to understand the basic requirements for ACO data management. The purpose of this study was to create a mock ACO data environment using currently existing data as well as modeled “synthetic” data environments to simulate the data needs and data challenges of a multi-organizational ACO.

Methods

We used currently existing de-identified hospital discharge data from the state of Texas to create two fictitious hospitals each with one year discharge rates of approximately 20,000 patients. Fictitious patient identifying information was created to provide patient names, date of birth, dates of service and unique hospital medical record number. Data for each hospital included diagnoses, procedures, outcomes and detailed charge and reimbursement information. Outcome information was derived from provided ICD-9 codes for in-hospital events. Risk algorithms were created using available demographic and diagnostic information.

Physician practice data was modeled using simplified EHR data structure and included patient demographics, encounter level data including diagnosis, procedures and charges. Charge and reimbursement information was simulated using Medicare fee schedules as a percent of private pay reimbursement. Meaningful use clinical and process measures were simulated. Clinical data was modeled using published incidence and prevalence information when available. Physician panels were set to between 1800 and 2200 patients. The created physician practices included two primary care, one OB/Gyn, one cardiology and one orthopedic practice. There was no master patient identifier between organizations.

Conclusions

This “synthetic” ACO environment allows users to query relatively straight forward information on utilization, clinical measures and outcomes but also allows for users to create a simple master patient index, evaluate inter-organization utilization and evaluate outcomes, capitated contracts over time and longitudinal cost of care.
Designing iSee, the intelligent Search expansion tool
Ko-Wei Lin, DVM, PhD, Dexter Friedman, Hyeoneui Kim, RN, MPH, PhD
Department of Biomedical Informatics, University of California, San Diego, La Jolla, CA

Introduction and Background
Vast amounts of biomedical data became available, which we can reuse and assimilate to evaluate existing hypotheses and to make new scientific discoveries. Data abundance also poses new challenges, particularly in terms of the efficiency and accuracy of searching through this data, due to idiosyncrasies in its representation. It is often mentioned that a recommendation system would be potentially useful in facilitating the search of biomedical data. For example, the biomedical researchers we interviewed to collect user requirements for PhenDisco (http://phendisco.ucsd.edu), a concept-based search tool we built for dbGaP (http://www.ncbi.nlm.nih.gov/gap), suggested that we implement automatic search expansion (i.e. a “recommendation” feature) within PhenDisco. Unlike in commercial domains, such functionality has mostly been developed and used in an experimental setting in biomedical research.

bioCADDIE (biomedical and healthCAre Data Discovery and Indexing Ecosystem, http://biocaddie.org) is a project that aims to facilitate the discovery and indexing of biomedical data in order to support large scale data analysis and reuse. iSee (intelligent Search expansion) is a pilot project funded by the bioCADDIE initiative. The main goal of iSee is to support efficient data search and review by intuitively expanding the user’s search to return highly accurate records in an easily assessable manner. iSee is to be developed as a new feature in PhenDisco. We are piloting this idea with PhenDisco as it already has search functions that iSee can expand and it contains annotated phenotype data with standardized metadata. iSee development involves two parts: (1) generating record relevancy scores based on readily available standardized metadata and (2) designing an intuitive user interface. This work reports on the lessons learned during the initial requirement-gathering phase for the latter.

Methods
We reviewed 10 web-based biomedical data repositories and 5 commercial sites with data search capabilities to see how the automatic search expansion function is implemented. We also interviewed three biomedical researchers who are familiar with genome-wide association studies or genomics databases. During the interviews, we first gave a 10-minute presentation on the background and goal of iSee development, and provided a 3-minute demonstration with a straw-man iSee model to convey the iSee idea more clearly. iSee straw-man contained a study map in which relevant studies were arranged by metadata parameter similarities, a customized parameter selection section allowing users to prioritize the metadata relevant to their search, and a study information section. The goal of these interviews was to learn (1) realistic workflows around search and search expansion, (2) types of information that search expansion algorithms need to take as high priority, and (3) considerations on user interface designs.

Lessons Learned and Future Work
All biomedical websites we reviewed support an advanced search menu where users can refine search criteria. However, only two of them\(^1\) provide a function similar to automatic search expansion or recommendation, wherein the tool shows additional records comparable to the returned record of interest. These sites utilized metadata associated with the records/data to generate various views, thereby expanding its search further to other related records. The commercial websites all provide a recommendation system largely based on the users’ transactional log data, which was deemed less relevant to current iSee development.

The input from the biomedical researchers can be summarized as follows: (1) produce a view with comparable studies (i.e., expanded search returns) based on the default parameter setting, (2) allow users to refine/manipulate the comparable study view using the full set of available metadata, (3) allow users to set their own relevance criteria by assigning different weight to each metadata item, (4) an interactive graphical display is preferred but follow conventions to minimize the cognitive burden to understand the symbols and notations, and (5) although a bit cluttered, having more complete information available in one view is preferred to requiring additional user actions (e.g., mouse-over or clicking) to get to the necessary information. A revised iSee straw-man model is to be released in August of 2015. We plan to implant parameter similarity algorithm and metadata hierarchy in iSee system, and reevaluate the new model with a larger group of potential users.

Acknowledgment This work was supported by the NIH BD2K grant 1U24AI117966-01. We thank Drs. Melissa Haendel and Caroline Nievergelt, and Mr. Adam Maihofer for providing invaluable insights on iSee development.

Health Care Providers’ Perceived & Actual Problems in the Use of HIT in the ED

Mary L. Little, RN, MSN1, Osman Sayan, MD2, Vimla L. Patel, PhD1,3
1Dept of Biomedical Informatics, Columbia University; 2Dept of Emergency Medicine, Columbia University; 3New York Academy of Medicine, New York, NY

Abstract
Emergency Departments (EDs) are complex environments due to the interdependent, episodic, collaborative, nonlinear, and decision dense nature of the patient care.1 To gain a true perspective of provider perceptions and the reality of the ED workflow environment, recorded semi-structured interviews, ethnographic observations, recordings of patient handoff information, and digital sound pressure level (SPL) data were collected. The preliminary analysis indicates a mismatch between healthcare providers’ focus and perceptions of the seriousness of electronic health record (EHR) navigational difficulties, while ignoring the actual impact of task interruption and excessive noise levels on cognitive functioning. A discrepancy between providers’ perceptions and reality, suggests there may be a risk when health information technology (HIT) system changes are performed on interview data alone. Our findings suggest ethnographic observations in addition to interviews may be necessary to obtain a complete picture of an ED workflow environment prior to implementing any HIT system alterations.

Introduction
The ED environment is characterized by EHR time constraints and the need for urgency, information immediacy, rapid task completion, and task accuracy. If technology does not facilitate these activities, we suspect a mismatch between perception and reality will occur as providers focus on HIT interface navigation issues and overlook workflow impairment factors such as task interruptions and excessive noise levels which negatively impact cognitive functioning.2 Assessing the accuracy of provider perceptions and the reality of the healthcare environment is critical to effective HIT system alterations.

Methods
Nine detailed semi-structured interviews of ED resident and attending physicians were recorded to capture perceptions of HIT use in the ED, care coordination, and care quality and delivery. Fifteen care transition clinical rounds were recorded. All recordings were digitally encrypted, with patient health information (PHI) removed prior to transcription. Additionally, over 30 hours of digital SPL recordings were conducted in conjunction with ethnographic physician patient handoff and workflow task observations. Interview responses were coded using NVivo software,3 observations and patient handoff audio-recordings were analyzed separately. SPL data were analyzed by professional sound engineers and combined in a preliminary results analysis.

Results
Interview results revealed provider perception of the difficulties of working with HIT as being the most serious problem in workflow and task completion. While ethnographic observations revealed frequent interruptions by staff, consulting physicians, patients, and families, which often occurred during critical patient handoff information transfer. Noise levels, especially during high capacity time periods were much higher than anticipated with peak noise levels often greater than 90 decibels.

Discussion
Healthcare providers’ perceptions of the seriousness of EHR navigational difficulties overshadows the reality of the seriousness of task interruptions and high noise levels in the workflow environment. It is likely that providers’ HIT interface needs must be satisfied before attention to causes of cognitive impairment can be recognized or addressed.

Conclusion
Providers may perceive difficulties of working with technology a more serious problem than workflow issues affecting cognitive functioning. A mismatch in provider perception and the reality of the healthcare environment underscores the importance for researchers to gather ethnographic data or other forms of real life observations to assess the validity of healthcare providers’ perceived problems prior to HIT system alterations.

An analysis of PubMed4Hh App User Distribution
Fang Liu, MS, Paul Fontelo, MD, MPH
National Library of Medicine, Bethesda, MD

Abstract
PubMed for Handhelds (PubMed4Hh) is an app for finding relevant health information from the National Library of Medicine on mobile devices. Apple’s iOS app developer tool provides daily downloads data and regional distribution data. Comparison between PubMed4Hh download distribution and the regions of PubMed citations shows a consistent match between the number of users and the number of PubMed indexed publications of a region.

Introduction
The PubMed4Hh app has been on Apple iTunes store since July 2013. The app searches PubMed citations with multiple search strategies1. We observed consistently that 55% of PubMed4Hh app downloads are from outside the continental United States. At the end of 2014, more than 230K downloads were recorded for iOS devices.

Methods
Apple’s iTunes Connect provides daily and yearly download data to applications’ developers including data on regions and locations. PubMed statistical reports show the countries and the number of citations from these countries’ grants respectively2. From the PubMed database, the number of citations for multiple languages can be retrieved by setting the different language filters. We analyzed the data from iOS downloads from the iTunes and statistical reports of the most PubMed grant countries from the PubMed citations database.

Table 1. PubMed4Hh app download by country; PubMed Citation in multiple languages and PubMed grant countries

PubMed4Hh app was downloaded by users from 124 countries. In 31 countries (25.0%), there were more than 1000 copies of the app downloaded and in 24 countries (19.3%), more than 100 but less than 1000 apps were downloaded (Table 1). Languages spoken in the top 10 downloading countries are English, Spanish, Portuguese, Italian, German, Chinese and Dutch. Four PubMed Grant countries (US, UK, IT and CA) had the highest downloads. From the PubMed citations database, languages used by the most downloading countries all have large numbers of citations of that language ranging from 63K to 20M.

Conclusion
Data analysis shows the countries that had the highest PubMed4Hh app downloads all have a significant number of citations in PubMed. The topmost PubMed grant countries were also countries that had the most PubMed4Hh app downloads.

Caveats of Using Social Media Data for Medical Research: A Report from a Study on Eye-Related Symptoms in Tweets

Yang Liu MSJ,1 Tricia O’Brien,2 Esha Sondhi,3 Qiaozhu Mei PhD,1,4 David A. Hanauer MD, MS,5,1 Kai Zheng PhD6,1
1School of Information; 2College of Literature, Science, and the Arts, 3College of Engineering; 4Department of Electronic Engineering and Computer Science; 5Department of Pediatrics; 6School of Public Health Department of Health Management and Policy, University of Michigan, Ann Arbor, MI, USA

Introduction
Social media websites are increasingly used by the general public as a venue to express health concerns and disseminate information during public health crises. Numerous prior studies have demonstrated that social media can be a valuable source of information for purposes such as early detection of disease epidemics and clinical and public health research.1 Nevertheless, researchers have also cautioned about the use of social media data because such data, which could be generated by anybody on the internet, are inherently noisy.2 In this study, we applied MetaMap to a random sample of twitter messages to identify potential mentions of eye-related sign/symptom concepts. We then conducted a manual review of the results extracted by MetaMap to assess their medical relevance. The objective was to identify non-medically relevant tweets that may be ‘mislabeled’ by MetaMap, and common reasons for this mislabeling.

Methods
We analyzed a 10% random sample of all geo-tagged English tweets generated in 2013 collected through the Twitter stream API with Gardenhose access. Clinical concepts in the tweets were extracted using the natural language processing tool MetaMap.3 Two coders then manually reviewed a random sample of the MetaMap-produced results to identify tweets that were not medically relevant. In this process, the two coders also classified the non-medically relevant tweets into categories that best characterize the reasons for their being mislabeled.

Results
Out of approximately 300 million tweets analyzed, MetaMap identified 291 distinct types of “signs” and “symptoms.” 16 of them were considered as eye related by two ophthalmologists (e.g., bloodshot eye, blurred vision, redness of eye). These 16 eye-related signs and symptoms appeared in 25,883 tweets, 1,555 of which were manually reviewed till saturation was achieved (i.e., no new categories continued to emerge from the data). Out of these 1,555 tweets, the two coders agreed on 1,387 of them regarding whether they were medical relevant. The inter-rater agreement rate (Cohen’s kappa) is 0.76.
Among these 1,387 tweets, 960 (69.2%) were deemed as non-medically relevant by both coders. The most common reasons for mislabeling include “different meaning” (39.4%), “lyrics/poem/quote” (19.5%), “emoticon” (12.9%), “words out of order” (8.3%), “circumstantial” (7.6%), and “idiomatic” (7.3%).

Conclusion
In this study, we demonstrate that MetaMap, a popularly used medical named-entity extraction tool, performed very poorly in extracting medical concepts from tweets, a common type of social media data. Of the tweets identified by MetaMap as containing medical relevant concepts, 70% were deemed by the two coders as non-medically relevant. Extreme caution shall be therefore used when applying NLP tools to extract medically relevant content from social media for disease surveillance or for research.

A Cross Strait Cooperation Design and Implementation of Mobile Nursing Information System

Yun Liu, MD1, Pinjen Huang, MS, RN2, Zejuan Gu, RN3, Rong Wang, RN3, Chunhong Gao, RN3, Tao Shan1, Jianjun Guo1, Zhongmin Wang1

1Jiangsu Province Hospital Information Department, Nanjing, China; 2MiWell, Taipei, Taiwan; 3Jiangsu Province Hospital Nursing Department, Nanjing, China

Introduction

Under China’s 12th Five-Year plan, hospitals need to adopt EHR, change nursing care model from functional care to primary care, and manage nursing workload in a scientific way. Based on above guideline, we evaluated current nursing information systems in China, and could not find any of them meets the requirement. Our original nursing information system is an add-on function to health information system (HIS) and each nursing ward would be equipped with 1-2 desktops for nurses to access HIS. Nurses have to print out orders on papers daily, or whenever physicians update their orders. After giving medication, nurses need to sign the paper forms; those forms would be kept for 14 days and then discarded after patient discharged. Taiwan has rich ICT resources and the development of nursing information systems there is sophisticated and relatively mature. We consulted Taiwan’s nursing informatics experts and identified a start up company with a prototype of mobile medication administration record system (mMAR)2 which was implemented with a qualified design concept. The company was invited to cooperate with us to redesign a new mobile nursing information system (mNIS). The implementation of the system was separated into two phases: phase one is order execution associated nursing process, and phase two is nursing plan and nursing documentation. In this study, we will share our phase one experience from design to implementation.

Materials and Method

This study was conducted in a more than 3,000-bed medical center in Nanjing city. The mNIS committee was setup in Oct 2013, led by nursing deputy director. The members include head nurses, a nursing informatics PM, an engineering PM, an user experience designer and engineers. During process redesign, physician affair director, laboratory director, blood bank director and pharmacy director joined every process discussion. We implemented barcode-printing function in pharmacy intravenous admixture services (PIVAS) so nurses don’t have to do the medication label cutting and pasting. During the implementation of mNIS, hospital HIS rules were also clarified. Physician’s prescription behaviors were therefore standardized and nurses don’t have to judge the first dose of medication purely based on experience. All information associated with medication administration, blood transfusion and blood sampling was integrated into one system, which used to be separated in different portals. We chose MioCARE A105, an Android 4.0 tablet 6” display and integrated with 2D barcode scanner as our main system interface. C++, Java were used for developing the native app, task server, and sync server, while PHP was used for web portal implementation. SOAP and Socket were used for exchanging data with each hospital’s information system. Phase 1 contains 3 process (medication administration, blood transfusion and blood sampling) and 9 modules. Two geriatric wards were selected as power users, they were trained and feedback to mNIS committee module by module from August to November 2014. From mid of Dec 2014 to Mar 2015, power users were asked to use paper forms and mNIS in parallel. A 5-point Likert scale questionnaire designed by Technology Acceptance Model for Mobile Service (TAMM) model was used to evaluate nurses’ acceptance of mNIS. There were 14 nurses invited to answer the questionnaire at the first week of Mar 2015.

Result and Conclusion

The highest score of questionnaire was Ease to learn (4.24 out of 5) follow by Ease to use (4.16), Usefulness (3.73), Trust (3.72), Acceptance (3.7), and Satisfaction (3.55). The questionnaire indicated a positive feedback from nurses even with some extra loading caused by the request having mNIS and paperwork processes running in parallel. We will optimize the phase one performance then go live on 60 wards separately before the end of 2015.

Developing Clinical Decision Support for Patient Self-Management: A Prototype for Symptom Management in Cancer Patients

David F. Lobach, MD, PhD, MS1; Janet L. Abraham, MD2; Donna L. Berry, RN, PhD2; Michael S. Rabin, MD2; Ilana Braun, MD2; Manan Nayak, MA2; Mary E. Cooley, RN, PhD2
1Klesis Healthcare and Duke University Medical Center, Durham, NC; and 2Dana-Farber Cancer Institute, Boston, MA

Abstract
Patient-centered care includes enabling patient self-management. Improved clinical decision support (CDS) tools designed for direct use by patients are needed to empower patients to self-manage their symptoms. We used a formative process to design a prototype CDS tool for self-management of symptoms by cancer patients. This prototype reflects design principles created to address patient barriers and clinician concerns for patient use of CDS. Patient usability surveys indicated strong support for the CDS tool.

Introduction
Relatively few rule-based CDS tools have been developed to directly assist cancer patients with symptom self-management.1-4 In those studies, the focus of the CDS was rudimentary1, relied heavily on interactions with clinical personnel2,3, or was implemented as a subcomponent of more comprehensive cancer information system.4 The goal of this formative study was to identify and create a prototype CDS tool that overcame identified patient barriers and clinician concerns regarding the direct use of CDS by cancer patients for symptom self-management.

Methods
This project focused on the most common symptoms contributing to emergency and urgent care visits among patients with cancer, namely pain, constipation, and nausea and vomiting. Our multi-disciplinary research team conducted a formative mixed methods study involving focus groups, interview sessions, and usability surveys with cancer patients, their caregivers and oncology clinicians. All focus group and interview discussions were audio-recorded and content was transcribed for analysis. Based on the data gathered and on input from stakeholders participating on expert panels that included patients, caregivers, clinicians, information system developers, and administrators, we identified patient barriers and clinician concerns regarding the use of CDS by cancer patients for symptom self-management. Addressing these barriers and concerns led to design principles that informed CDS tool prototypes to simulate design and content features of a self-management CDS system for patient symptoms to which study subjects could respond.

Results
We recruited 24 patients and 13 oncology clinicians to participate in the formative evaluation. CDS design principles addressed patient safety, cultural competency, care coordination, resource availability, and system function. Specific features of the prototype included identification of emergency issues, specific details for when and how to contact the clinical team, access to explanatory information, and expedited data collection to place users at the appropriate place within the CDS algorithm. Patient usability surveys indicated strong support for the CDS tools.

Conclusions
The findings from this study provide insight into how CDS systems can be developed to support patient self-management directly. Patient safety and tool navigation were critical features. Many of the insights gleaned from this study may be generalizable and could inform the development of CDS resources that patients with other diseases and their caregivers can use for self-management of symptoms.

Acknowledgements
This project was funded in part by The Patient Centered Outcomes Research Institute Grant PI-12-001.

Real-time SNOMED Post-coordination of Adverse Drug Reactions: Model Formulation for an Actionable Registry

Marcelo Lopetegui, MD, MS¹,², Mario Barbé, MD¹, Daniel Luna³, Alejandro Mauro, MD¹
¹ Clínica Alemana de Santiago, Facultad de Medicina, Universidad del Desarrollo, Santiago, Chile
² Department of Biomedical Informatics, The Ohio State University, Columbus, Ohio, USA
³ Health Informatics Department, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Introduction
Prevalence of allergies has increased in the last 50 years: currently 40-50% of the population presents some level of sensitization, while 10% will present an adverse drug reaction¹. Two percent may present an episode of anaphylaxis in their lifetime, with a reported lethality of up to 2%.² Thus, updated and accurate allergies records are key for a safe patient care. Furthermore, appropriate allergy records in interoperable environments could decrease medication related errors³. In this context, we aimed at developing an allergies registry module in our home-grown Electronic Health Record (EHR) attempting to achieve two main outcomes: maintain updated allergic status for our patients, and do it on a manner that produces actionable data we could leverage, all while being minimally disruptive in the usual clinical workflow.

Methods
Updated and meaningful allergic status. Based on user-centered design, we defined four allergic statuses: unknown, positive, negative, and outdated. The allergic status is always visible in the patient header, allowing for a quick and meaningful assessment of the allergic status of the patient. The unknown status (never asked) is expected to provide an evident differentiation from a negative status (answered no), motivating the clinician to assess the patient’s initial allergic status. In order to ensure updated data, we configured the module to consider the status valid for one year. Following international recommendations, we decided to require the allergy status to be up-to-date in order to prescribe a new medication in the Computerized Physician Order Entry (CPOE).

Fast data entry and actionable data. Text fields provide fast data entry, but are hard to computationally act and reason upon, while simple lists provide limited sets of structured data. We desired fast data entry without compromising the quality and usefulness of the registered data. Thus, we developed a real-time concepts post-coordination module, which, based on SNOMED CT, permits the clinician to easily enter any potential allergic status, identifying the causing agent (drug, food or environmental agent), the symptoms and signs, and the severity. The result is a completely customized list of allergies for each patient, recorded with all the appropriate relationship types to existing SNOMED CT concepts.

Results
A first version of the module was deployed in our emergency department information system for verification purposes, currently ongoing stability upgrades. The evaluation of the proposed model will be conducted in the outpatient setting based on a pre/post assessment of the proportion of patients with a reported allergic status, the proportion of patients with statuses updated within the last year, the assessment of the perception of the module by clinicians, and with a feasibility study of cohort creation based on detailed allergic statuses.

Conclusion
We present a model to manage the registry of adverse drug reactions and allergies in a home-grown EHR, providing an actionable registry based on post-coordination of standardized concepts, and expecting to improve allergic status completion and validity. Ongoing assessment will be presented in a future report.

Mapping Workflows in a Surgical Clinic to Guide Implementation of a Patient-Centered Postoperative mHealth Wound Assessment System

Ross Lordon, BS1, Heather Evans, MD1, Andrea Hartzler, PhD2, Cheryl Armstrong, BSN RN MPH1, Sarah Whitehead, ARNP MN1, Patrick Sanger, PhD1, William Lober, MD1

1University of Washington, Seattle, Washington; 2Group Health Research Institute, Seattle, Washington

Intro: The successful adoption of novel health information technology (HIT) is often challenging and susceptible to a multitude of problems. Poor design, lack of planning, ineffective implementation, or an absence of socio-technical support post-implementation, can cause technology to be underutilized or abandoned entirely. Effective implementation demands a comprehensive understanding of the current work processes of the target environment. Once established, it is imperative to closely align new technology with current work processes to minimize frustration during implementation1. Anticipating user needs, such as nurses integrating patient generated mobile health (mHealth) data with the electronic health record (EHR), for implementation is paramount. Specifically, our team is implementing an mHealth platform to facilitate patient self-tracking and communication with providers about the signs and symptoms of surgical site infections after hospital discharge. Patients utilize an mHealth application and providers access the patient generated data on a computer based dashboard. Unfortunately, we lack guidance on workflow mapping for implementation of mHealth platforms in clinical settings. The majority of guidance on HIT workflows focuses on EHRs and decision support, such as alerts and reminders. To explore this gap, we examined the adaptation of existing HIT workflow assessment tools recommended for EHRs, such as benchmarking and flowcharting,3 to prepare for the implementation of an mHealth platform in surgery care. Methods: We conducted semi-structured interviews with staff in a plastic surgery clinic to map the existing workflows for utilizing wound photos submitted by post-operative patients. We formally documented these workflow processes using business process-modeling notation (BPMN), a form of flowcharting.3 Once the existing workflows had been visualized in the first BPMN diagram, we produced a second BPMN diagram depicting the proposed changes to the existing workflow. We presented the second BPMN diagram to all the stakeholders involved with the mHealth platform implementation. Barriers, opportunities, and weaknesses were identified and included in subsequent revisions. Results: After three rounds of iterative revisions, the BPMN diagram helped us to align the implementation of the mHealth platform with current clinic work processes. Next we used our findings to draft a new BPMN diagram depicting workflow processes after future implementation of the mHealth platform. Then we presented this to the clinic and mHealth development team to guide the implementation process. Using this diagram, the mHealth development team and clinic staff identified specific components of the workflows that will provide evaluation metrics to assess process improvements after implementation. Examples of metrics include, nurses’ time spent discussing wound concerns with patients, time spent documenting concerns in the EHR, and time to resolve reported problems. Discussion: Generating BPMN diagrams demonstrating clinic workflow processes before and after the mHealth platform implementation helped us gain the confidence of the clinic staff, streamline the implementation planning process, and lay down a critical foundation for the implementation of our mHealth platform in clinical care. Through this iterative process, we gained insights into the multiple ways a patient could initiate communication about wound concerns. We incorporated these insights into new workflows and evaluation metrics to facilitate future implementations. Thus, the BPMN diagrams helped inform the new workflow processes with the intent of minimizing disruption to the current workflow within the clinic. The subsequent implementation phase will incorporate producing a third BPMN diagram to depict the actual post implementation workflows. This will allow us to compare the anticipated new workflows to the actual post implementation workflows. In future work we will also observe the pre-implementation workflows in the clinic to complement the stakeholder interviews. Conclusion: There is a need for a structured approach to mHealth platform implementation in clinical settings. Translating existing HIT workflow assessment tools to the mHealth domain has shown tremendous value in guiding our implementation process.

Using OpenEMR in HIT Training at Columbia

Virginia Lorenzi, MS, CPHIMS 1,2, Anthony McCormick3,4, Brady Miller, MD3, Kenneth Newman, DMD, PMP5, Carol Smyth, MB6; Fred Rahmanian, MS7, Frances Morrison, MD, MPH, MA2
1Department of Information Technology, NewYork-Presbyterian Hospital, New York, NY; 2Department of Biomedical Informatics, Columbia University, New York, NY; 3OEMR; 4Medical Information Integration, LLC; Catholic Health Services of Long Island; 6Medivo, Inc. New York, New York; 7KPMG, Inc., Malvern, PA

Introduction

The Columbia Certification of Professional Achievement in Health IT is a nine-month, credit-bearing program that provides broad training in Health IT to a professionally diverse student body. A goal of the program is to provide students with hands-on lab experience using current, relevant technology. From the initial funding in 2011 as part of the ONC Workforce University Based Training program, we looked at working with various vendor and free online EHRs, but these were expensive, difficult to access, or un-configurable. We decided to use OpenEMR, which was not only free and open source, but also ONC-certified. OpenEMR has provided a readily available, configurable platform that has added benefit to the students’ experience in many ways.

Methods

OpenEMR was installed on a server external to the closed University and Hospital systems in order to be accessible to students and external instructors. The system became an easily accessible playground that allowed our students to play many different roles, from user to system administrator. Students became accustomed to EHR functionality by entering fictional patient data, which was added to imported de-identified data. Later assignments included querying the OpenEMR database. Because OpenEMR was ONC 2011 certified, it was ideal for coursework that involved implementation for meaningful use; students created a mock project plan that involved an implementation in a fictional clinic.

Students also had the opportunity to collaborate with the open software community in real-time challenges. As the nation rushed towards ONC 2014 certification and Meaningful Use Stage 2 attestation, OpenEMR also struggled with the challenge of upgrading to an ONC 2014 system. This challenge turned into a real-world problem scenario for the class, who found that their EHR was not certified in time for their mock clinic’s go-live date. The students learned about the Meaningful Use Stage 2 implementation struggles and the hardship and flexibility regulations. This enabled students to don the vendor role; they joined OpenEMR conference calls and were given real assignments that helped in the development and certification of an ONC 2014 certified version of OpenEMR.

Conclusion

Open source software provides an accessible, quality playground for students. We have found that using OpenEMR has helped us solidify a multitude of skills and has provided some unintended benefits. Our students learned about how open source is used throughout Health IT within products and how vendors value-add services. They were able to explore the EHR user, implementer, and developer role. They were able to build relationships within the OpenEMR community and perform useful work that they could use on their resume.

We feel that we can expand the scope of assignments that use OpenEMR, including projects related to interoperability, patient engagement, form design, analytics, decision support, and security and privacy. Since OpenEMR is a real system used in healthcare, we anticipate that it will continue to provide opportunities for just-in-time real world activities to enhance our students’ learning experience.
Designing a Plan Do Study Act Framework to Promote Proper Utilization of Early Detection Technology in the Acute Care Setting

Graham Lowenthal¹, Patricia C. Dykes, PhD, RN¹, Stuart R. Lipsitz, ScD¹, Catherine S. Yoon, MS¹, Ronen Rozenblum, PhD, MPH¹, Perry G. An, MD², Suzanne Salvucci, RN², Christine Shaughnessy, RN², David W. Bates, MD, MSC¹,³

¹Brigham and Women’s Hospital, Boston, MA, ²Newton-Wellesley Hospital, Newton, MA, ³Harvard Medical School, Boston, MA

Introduction: Patient monitoring systems allow for early detection of clinical decompensation and have been associated with improved quality of care, lower length of stay, and favorable healthcare cost outcomes.¹,² In January of 2013, an early detection system was implemented on all adult medical-surgical units in an Eastern Massachusetts acute care hospital. The purpose of this study was to identify barriers to effective use of the early detection system and, using a Plan Do Study Act (PDSA) framework, develop continuous quality improvement strategies to promote proper utilization.

Methods: We established a committee of key stakeholders, including physicians and nurse champions from all study units, researchers, and vendor partners. We (the committee) conducted regular meetings to identify barriers to optimal system use. We designed a multi-cycled PDSA framework to address each barrier by identifying specific strategies and tactics. We tracked use of the system and response times (in minutes) to system alerts to measure progress. At each committee meeting, we reported out on progress and gathered feedback to evaluate the effectiveness of each strategy. We then adjusted our approach, set new goals, and executed revised tactics.

Results: We identified two major categories of barriers that could hinder effective system use. Educational barriers were those caused by a lack of awareness of the existence and importance of certain aspects of the system, and/or by unfamiliarity with using the system and features. Clinical Workflow barriers were related to challenges incorporating use of the system into everyday operations and communication.

We developed and tested several strategies for overcoming each barrier. To address educational barriers, we hosted a kickoff meeting to emphasize the importance of the system and proper utilization. We provided regular didactic and hands-on teaching sessions and coached staff on proper alerts management. In addition, we regularly reviewed recent clinical “saves” made using the device to demonstrate perceived system value. For clinical workflow barriers, we improved communication by integrating scripted discussion of the system, alerts, and trends into multidisciplinary rounds, EHR documentation, and handoff reporting. We mitigated alarm fatigue by enabling nurses to change device settings within specified limits to reduce unnecessary alerts and by providing several methods for receiving alert notifications (pagers, bedside monitors, and central nursing stations). We also strengthened our partnership with the vendor to address issues and concerns with the technology. We have noted improved response time trends to system alerts. Monthly overall mean response times have improved from 92 (range: 17 to 360) minutes at baseline to 54 (range: 4 to 127) minutes at present, mean Cardiac alert responses improved from 105 (range: 17 to 312) to 25 (range: 4 to 105) minutes, and mean Respiratory alert responses improved from 91 (range: 26 to 360) to 57 (range: 7 to 127) minutes.

Conclusions: Overall, our PDSA framework was effective for addressing barriers to proper utilization of early detection technology in the acute care setting. Since implementing the PDSA methodology, we have seen continuous improvement in system use and alert response times. We will continue using our PDSA framework to support proper system utilization and to decrease unit response times.

Variability in the Sequence of HL7 2.x Event Code Types used to Represent Encounters Across a Health Information Exchange

Tina Lowry, MS\textsuperscript{1}, Eugene Kim, MD\textsuperscript{1}, Joseph Johnson III, MBA\textsuperscript{2}, Jason S Shapiro, MD\textsuperscript{1}  
\textsuperscript{1}The Department of Emergency Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA  
\textsuperscript{2}J2 Interactive, Charlestown, MA, USA

Introduction:  
While developing encounter-based measures (frequent emergency department (ED) visits, early (72-hour) ED returns and 30-day hospital readmissions) across a health information exchange (HIE), we discovered a high degree of variability in the sequence of Health Level 7 (HL7) 2.x event code types (A01, A02, etc.) used to represent different types of encounters. This posed challenges in implementing encounter-based measures in a standardized manner. The objective of this study was to analyze and describe the degree of variability in the way HL7 2.x messages are used to represent three general types of encounters across an HIE: 1) treat and release ED visits, 2) ED visits leading to an inpatient admission, and 3) other types of encounters (direct admissions, same day surgeries, etc.).

Methods:  
HL7 messages were randomly selected from 30 of 31 acute care sites in the Healthix HIE in New York from 12/29/2014 – 02/02/2015. One site that did not use standard pipe-delimited separators in their HL7 formatting was excluded. The data was parsed using the Python library HL7APY with regular expressions applied to search for message segments and fields, creating a data set of patient encounters with the following data elements: HL7 event code type, acute care site, visit number (unique encounter identifier), medical record number (MRN – a unique patient identifier), patient class (nominally designates emergency, inpatient or outpatient visit type), and message date and time. Data were imported into SQL Server for further analysis and grouped by facility, MRN and visit number. Each group was then sorted by message date and time and assigned a sequence number. Event types were compared to patient class to show variation and better classify the sequence of event types. Message sequences were then manually reviewed by 2 reviewers to determine which sequences corresponded with each of three general types of encounters described above.

Results:  
We extracted 3,363 sample HL7 messages representing 323 patient encounters from 30 sites. Manual review yielded 32 patterns of HL7 event code type sequences: 5 unique patterns for treat and release ED visits, 18 for ED visits resulting in inpatient admissions, and 9 for all other visits. Each pattern not only gave insight into different workflows for each site but also the frequency of use and interpretation of specific event type codes. For example, A04 (register a patient) is generally used to indicate patient registration in the ED and begin the patient encounter sequence. This event type was used by all 30 sites for emergency visits. An A03 (discharge/end visit) event type code is normally used to end a visit. However, when ED visits resulted in inpatient admissions, only 2 sites used A03s, while 16 used A06s (change an outpatient to inpatient) or A02s (transfer a patient), 1 site used A11s (cancel admit/visit notification), 7 sites used A08s (update patient information), and 4 sites use direct admit A01s (admit/visit notification).

Conclusion:  
The high degree of variability in the sequence of HL7 2.x messages used by acute care facilities to represent different types of encounters may confound attempts to apply encounter-based measures to an HIE dataset without further normalization. The sequences described in this analysis will be used to map all encounters in the HIE dataset to standard encounter types in order to validate and more accurately apply encounter-based measures. This issue likely exists in other HIEs where standard HL7 2.x has been implemented across multiple acute care facilities. In the future, use of XML-based standards (e.g., C-CDA) to aggregate encounter-based information in an HIE may obviate the need for this type of analysis and normalization, but further investigation will need to be done to determine if similar issues exist regardless of messaging standard employed.
Generating the MEDLINE N-Gram Set

Chris J. Lu, Ph.D.1, 2, Destinee Tormey1, Lynn McCreedy, Ph.D.1 and Allen C. Browne 1
1National Library of Medicine, Bethesda, MD; 2Medical Science & Computing, Inc, Rockville, MD

Abstract
The MEDLINE n-gram set is a very useful resource in Natural Language Processing (NLP) and Medical Language Processing (MLP). Currently, there is no MEDLINE n-gram set available in the public domain. Due to the large scale of data, it is a challenge to generate MEDLINE n-grams to fit into a research schedule with limited computer resources. The Lexical System Group (LSG) developed an algorithm to generate the MEDLINE n-gram set for adding multiwords into the SPECIALIST Lexicon. We believe the NLP community can benefit from access to this big data. We processed 2.6 billion single words from 22.4 million MEDLINE documents (titles and abstracts) to generate MEDLINE n-grams (n = 1 to 5) with terms appearing at least 30 times and having less than 50 characters for the 2014 release.

1. Background, Motivation, and Challenge
The LSG used the MEDLINE n-gram model to generate multiwords in 2014. A sophisticated algorithm has been developed to generate a comprehensive MEDLINE n-gram set to replace the approximated n-gram model by prediction filter [1]. N = 1 to 5 were chosen because these terms cover up to 99.47% of the terms in the Lexicon, as shown in Table-1. Also, 99.55% of terms in the Lexicon have less than 50 characters and thus terms with more than 50 characters are filtered out. Both word count (WC) and document count (DC) are calculated. The approach of deriving n-grams by bigrams doesn’t provide accurate WC/DC. Titles and abstracts from 22,356,869 MEDLINE documents are collected and then tokenized to 126,612,705 sentences and 2,610,209,406 words (tokens) in the 2014 release. Our sentence tokenizer found very few unrecognized sentence patterns (0.01% - 14,314). Java class (HashMap) is used for the key-value mechanism to store n-grams as keys and their associated information (WC, DC, and PMID) as values in the process. This system works perfectly for unigrams and bigrams. However, this approach does not work for n-grams where n > 3 because the number of terms (keys) exceeds the limit of maximum keys in the Java HashMap class (230-1). The processing time is not feasible (it can take months) when using persistent key-value DB or other database (embedded or server) approaches to replace the Java HashMap, even with a powerful computer that has 192 GB memory.

2. Approach – Split, Group, Filter, Combine, and Sort
An algorithm was developed to resolve the issues stated in the previous section. First, it splits the MEDLINE documents into S sections so that n-grams of each section can be generated within Java limitations. Note that duplicated terms are distributed across S sections. Second, it retrieves unique terms (keys) and calculates WC and DC by grouping terms from a range of alphabetic characters, such as terms from ‘c’ to ‘f’, through generated S sections. Each range of grouped (unique) terms, which are within Java limitation, is saved into G groups. Third, it applies WC and DC filters through all groups and then combines all filtered terms to form the n-gram set. Fourth, it sorts the n-gram set by DC, WC, and the alphabetic order of terms. For example, 20 sections of 5-grams were generated from MEDLINE titles and abstracts. Then, 14 groups with different ranges of alphabetic characters of unique 5-gram are retrieved from these 20 sections. The program combines the 5-grams by filtering out the low frequency terms from these 14 groups. Table-2 shows 1.54M 5-grams with WC >= 30 are retrieved from 1.67G 5-grams in this step. Finally, these filtered 5-grams are sorted and saved in a file. The idea is to keep those large numbers of invalid n-gram terms (N = 3 to 5) in different sections and groups, to resolve the Java limitation issue. The WC and DC filter is then applied to remove these low frequency (invalid) n-gram terms before the final combination.

3. Conclusion
The 2014 MEDLINE n-gram set is successfully generated by the above method. Table-2 shows the number of each n-gram. Three fields (document count, word count, and n-gram) are included. The MEDLINE n-gram set is distributed annually by the National Library of Medicine (NLM) with the SPECIALIST Lexicon annual release via an Open Source License agreement [2].

Abstract

We report preliminary findings associated with the development of an electronic family-health information management system (eFHIMS). A directed content analysis of family caregiver focus groups was conducted to identify the extent to which Hispanic caregivers apply and perform self-management skills and tasks, respectively, as a basis for generating participatory design activities. Technology use was mentioned more than any other skill by caregivers to address and/or accomplish self-management tasks.

Introduction

Technology-based caregiver interventions can improve decision confidence, reduce emotional strain, improve spousal relationship conflict, decrease activity restriction, increase self-efficacy, and decrease burden\textsuperscript{1,2}. Nonetheless, electronic information management systems can assist caregivers manage health care services encounters and execute healthy behaviors for themselves and a family member living with dementia. The purpose of this poster is to present preliminary caregiver focus group findings associated with the development of an eFHIMS.

Methods

Based on a multi-phase system design approach, Consumer-centered Participatory Design, we conducted four focus groups (i.e., 2 English and 2 Spanish)\textsuperscript{3}. Audio recordings were transcribed and coded in the language of the group. A directed content analysis was conducted using the concepts present in Lorig and Holman’s self-management framework. The aim was to identify the extent to which Hispanic caregivers apply and perform self-management skills and tasks, respectively, in the context of health and health care as a basis for the participatory design phases.

Results

Caregivers were mostly female (90\%) with an average age of 81 years, more likely to be a daughter of a person living with dementia, and had been caregiving on average for 7 years. Caregivers expressed using or needing all of the self-management skills (i.e., problem solving, decision making, resource utilization, formation of patient-provider partnership, action planning, and self-tailoring) to accomplish the three self-management task (i.e., emotional, physical, and role management). Caregiver’s ability to utilize resources was the skill most often mentioned (n=73) to address self-management tasks. Notably, technology utilization, a sub-classification of resource utilization was mentioned more (n=43) than the other skills which ranged from 15 for self-tailoring to 33 for decision-making.

Conclusions

Hispanic caregiver’s technology utilization will be an important consideration as we develop the eFHIMS. This knowledge will be used to motivate design activities to elicit requirements of information technology use.

Bridging the Representation Gap of Medical Image and Clinical Note through Semantic Association Mining

Jake Luo1,2 PhD, Timothy Patrick1,2 PhD
1 Department of Health Informatics and Administration, University of Wisconsin Milwaukee, Milwaukee, WI; 2 Biomedical Data and Language Processing Center, University of Wisconsin Milwaukee, Milwaukee, WI

Abstract: Medical images and text are two of the most important forms for delivering clinical information and knowledge. Automatic integration of image knowledge and text knowledge can greatly assist clinicians in diagnosis, biologists in searching for evidence. However, the lack of a shared knowledge representation for images and text poses a significant barrier to the development of new applications that take advantage of this potential integration. This project aims to bridge the gap by systematically integrating image-text information to develop a knowledge base using natural language processing, medical image processing, and ontology-based knowledge integration methods. The image-text knowledge base can be a great help for clinical and translational research. For example, physicians can use the knowledge base to create semantic queries for searching patients with two criteria: one specified in clinical note “diagnosed with brain tumor in the past three months”, and the other specified in the image “nodules larger than 5mm at the pineal gland on MRI”.

Method: In stage 1 (See Figure 1 stage 1), we used the University of Washington Radiology case dataset to extract radiology report titles, figures, clinical notes, and captions. In stage 2, we parsed all the images and clinical notes from the datasets and store them in a database. We used a semantic annotator to automatically extract medical concepts from the clinical notes that described the medical image. The semantic relationships of the medical concepts were identified using a natural language processing method. The association of image components and textual clinical concepts were linked manually. In stage 3, we extracted semantic predicates from the annotation. For example in figure 2, we can also aggregate all patient cases that had radiosurgery on the brain through the reasoning of RDF triples “Therapeutic Procedure -> treats -> Neoplastic Process” and “Neoplastic Process -> Occurs_at -> Body Part”. We call these image-enriched semantic predicate. We stored all the predicates into a knowledge base using semantic web technologies (e.g. RDF store) for convenient information retrieval and analysis.

Assessment of impact of guideline changes in CDS for cervical cancer screening and surveillance

Kathy L. MacLaughlin, M.D.1, Ravikumar K.E., PhD,1 Kavishwar B. Wagholikar, MD, PhD, Marianne R. Scheitel1, Hongfang Liu, PhD1 and Rajeev Chaudhry, MBBS, M.P.H.1
1Mayo Clinic, Rochester, MN, USA 2Massachusetts General Hospital, Boston, USA

Introduction
Complexity in cervical cancer screening and management guidelines and lack of personalized care recommendation systems poses a significant challenge to appropriate individualized care recommendations in cervical cancer screening and surveillance care process models. Clinical decision support systems (CDSS) offer a great potential in mitigating some of the challenges thereby improving cervical cancer screening and surveillance guideline compliance. At Mayo Clinic, we have developed a CDSS to automate standard guidelines based on information available in electronic medical records (EMRs) for cervical cancer screening and surveillance at the point of care. However, revision of these guidelines has posed a significant challenge to the development of the CDSS. In this work, we studied accuracy of the CDSS system after updating it to implement the latest revision of the guidelines. In an earlier study1, we assessed the performance of a CDSS for cervical cancer screening and surveillance.

Methods
The system extracts 10 data elements such as age and history of CIN 2/3, test values from both structured resources such as problem list and unstructured data sources such as cervical cytology report and clinical notes. It then makes care recommendations based on a set of decision rules2 (more than 55 decision scenarios). The rules were implemented in Drools rule engine3. We extended our earlier implementation1 by adding additional decision rules.

Data set and Validation
The CDSS system was run on 2,521 patients. Not all of the possible end points were represented in the batch sample that was acquired. We performed a stratified sampling on 191 of those patients, covering every decision end-point based on the extracted data elements (cytology, high-risk human papilloma virus and colposcopy biopsy results). The clinician expert evaluated the CDSS-generated recommendations by reviewing the medical record for each unique patient and compared them against ASCCP guidelines4, which allowed identification of errors in the CDSS.

Results and Discussion
Of the 191 patients reviewed, the CDSS-generated decision was correct in 151 cases, leading to an overall accuracy of 82%. Figure 2 outlines the error percentage distribution as per the decision endpoint. Analysis of errors revealed that in four patients, even though the final recommendation was correct, the process flow and endpoint was incorrect. We observed a drop in the accuracy by 5% when compared to earlier reported results by our group (accuracy of 87%). The drop in the performance of CDSS may be due to the increased complexity of the updated ASCCP guidelines4.

Conclusion
In this study, we evaluated the performance of the updated CDSS. While the revision of the practice guidelines resulted in increased complexity that impacted the performance of the system, a systematic error analysis coupled with stratified sampling helped us understand the micro behavior of the CDSS. We soon plan to deploy the system in big data environment and perform a large-scale evaluation on the impact of clinical care recommendations for cervical cancer prevention at the point of care.

A Framework for Incorporating Changes to a Reference Terminology on a Mapped Enterprise Terminology Subset

Sina Madani, MD PhD\textsuperscript{1}, S. Trent Rosenbloom MD MPH\textsuperscript{2}
\textsuperscript{1}The University of Texas MD Anderson Cancer Center, Houston, TX; \textsuperscript{2}Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN

Introduction
Enterprise vocabularies that are mapped to or subsetted from reference terminologies can be used within health care organizations for documenting and representing common patient data at the point of care. Such custom vocabularies are often developed internally, enriched with domain-specific terms, and linked to concepts from external reference terminologies. However, reference terminologies are updated frequently by their publishers. This can contribute to the burden of managing updated codes to the health care organizations.

A patient problem knowledge base (PKB) vocabulary subset of SNOMED CT has been in use at the Vanderbilt University Medical Center since 2011. All 112,319 concepts in this terminology have been mapped to equivalent SNOMED CT concepts, locally augmented with additional terms extracted from patient notes, and maintained in a commercial terminology server. Periodic synchronization of PKB terminology mappings to the latest release of SNOMED CT is essential for ongoing Vanderbilt EMR system and operational use.

Methods
From 112,319 PKB concepts, all concepts with retired SNOMED CT 2013 codes (2,692) were retrieved from the terminology server. For these retired PKB concepts, we identified five SNOMED CT historical relationship types in our terminology server and retrieved the mapped concepts. We acknowledged the updated SNOMED CT (2014) target concept codes for the retired PKB concepts from 4 relationships and only reviewed 300 PKB concepts with the retired SNOMED concept that had a “May be a” historical relationship (Table 1). The two authors reviewed the updated concept codes and associated terms for compatibility with the exiting PKB terms, using a four value voting system. Disagreements were reconciled iteratively through discussion, with persistent disagreements reported here.

Results
Based on the updated version of SNOMED CT, 387 target terms from “May be a” relationship were identified for the 300 PKB concepts with retired SNOMED CT codes. We compared these targeted new terms with the existing 2,764 PKB terms associated with 300 concepts and evaluated their correctness (Table 2). The disagreement rate on the suggested new terms was decreased from 45 concepts to 32 and 9 respectively after two reconciliation sessions between the two reviewers. “Miscarriage”, “Termination of Pregnancy”, and “Pregnancy with abortive outcome” were the main sources of disagreements among representational variations of the 9 concepts with 22 terms.

Table 2. Verdict results on target SNOMED terms against PKB terms

Discussion
We will use the results of this study for the proper update to the mappings of our internal vocabulary system. Suggested new mappings with questionable outcome will be re-examined against the future versions of SNOMED CT and updated accordingly. Although the terms in questions were reasonably consistent with their definition in the Unified Medical Language System, the ambiguity in their representation made it difficult for the reviewers to judge universally. This overlaps with the issue of synonym drift that has been described elsewhere in the terminology mapping domain.
Title
Choosing to Build: Optimizing the Development of a Custom Pathology Laboratory Software Solution

Authors
Emilio Madrigal¹, Victor Brodsky²
¹Department of Pathology, Mount Sinai Health System, St. Luke’s, Roosevelt, and Beth Israel Hospitals, New York, NY, USA
²New York-Presbyterian Hospital/Weill Cornell Medical College, Pathology, New York, NY, USA

Background
Commercially available software seldom meets all the requirements of laboratory medicine. Customizations by vendors can result in additional costs and compromises, while using software as-is may lead to inefficient workflows and impact patient safety. At NYP/Weill Cornell we chose to create a responsive, web-based, multi-user application for submitting and tracking scan orders to a new whole-slide scanning service. We analyzed the amount of time and effort to design, build, and test a working solution, focusing on how prioritization of issues documented during development impact the time to completion in days (TC).

Design
Bitbucket was used as the distributed revision control system and issue tracker. Source code statistics for the project, built on Microsoft Windows 2012 with PHP, were generated using GitStatX. Developer productivity was measured using lines of code (LOC) written per-day by our software engineer, who holds a Master of Biomedical and Computer Engineering. A physician-informaticist (PI) responsible for conceptual design, functional specifications, and program testing was surveyed regarding his time commitment.

Results
The development team comprised 1.2 FTEs; the PI dedicated 0.2 of his time, spending 60% of it on software testing. The project took 451 days and contains 1999 files with 379,620 LOC (averaging 670/week). In total, 377 issues were documented, of which 325 were resolved, and 49 remained outstanding at launch; 204 (54%) were classified as bug, 163 (43%) as enhancement, 3 (1%) as proposal, and 7 (2%) as task. The top two priority flags assigned to bugs and enhancements were “blocker” and “critical”. The average TC for all issues was 29 days (13 for bugs, and 52 for enhancements) with a median of 9, and SD of 59.2. “Blocker” was used 24 times: 19 (79%) for bugs with a TC of 3.4, and 5 (21%) for enhancements with a TC of 6.6. “Critical” was used 221 times: 139 (62.9%) for bugs with a TC of 12, and 78 (35.3%) for enhancements with a TC of 39.2.

Conclusion
Although testing and issue documentation required a generous amount of time, prioritization positively impacted the rate at which development milestones were achieved. Issues marked with the highest priority of “blocker” were resolved 3 to 6 times faster than those flagged as “critical”. Additionally, daily LOC logs established a baseline expectation of activity. The use of issue tracking and version control systems provides an effective way of monitoring development in order to efficiently build software solutions.
Quantitative Evaluation of Dysarthria and Development of Vowel Sound Voice Training System

¹Kitasato University Graduate School of Medical Sciences, Sagamihara, Kanagawa, Japan; ²Kitasato University School of Allied Health Sciences, Sagamihara, Kanagawa, Japan; ³Tokyo Healthcare University Division of Healthcare Informatics, Setagaya, Tokyo, Japan;

Introduction

Dysarthria is a disorder of voice and articulation. It occurs with high probability after cerebrovascular disease, which eventually lowers patients’ quality of life. Therefore, rehabilitation and its evaluation are very essential for the patients’ quality of life after discharge. However, quantitative assessment of the dysarthria rehabilitation is not widespread because the instruments used for measurement at hospitals are expensive and not portable. To solve this problem, we developed a voice training system which works on usual PCs.

Methods

We developed an application which can record the patients' voices during vowel sound voice training, measure the duration and volume of the recorded voice, and calculate the formants based on frequency analysis. This application also has a training feature which provides visual feedback of the patients input to encourage the patient. The program was developed using Visual Basic 2010. The evaluation study was approved by the Ethic Committee of Kitasato University Hospital and all participants provided their informed consent for participation.

Results

Figure 1 shows an example of the output of the vowel sound voice training, in which a subject with cerebral infarction (hoarseness, non-hoarseness) was able to continue the training for 2 or 3 seconds, and it was found that the power spectrum of the second formant frequency band with non-hoarseness is larger than hoarseness. Visual output was able to be used as a bio-feedback interface, which encouraged the patient to utter louder and longer.

Conclusion

We developed an application which can be used for the quantitative assessment of dysarthria and the vowel sound voice training. To evaluate the usefulness of the system, we are studying cerebral infarction patients.

Designing a drawing-based tool to manage EBRT process in an open-source oncology EMR system

Manika Maheshwari, Saptarshi Purkayastha
School of Informatics & Computing, Indiana University-Purdue University, Indianapolis, USA

Problem
External beam radiotherapy (EBRT) is a complex treatment process that requires appropriate communication and planning between the oncologist, interventional radiologist and the radiology technician. Hand drawn images or annotations on radiology images are often used for communication. Cone beams, angles, treatment ports, dose distribution curves are in a state of constant flux particularly when used in conjunction with modern image-guided (CT or X-ray) radiation therapy. Treatment procedure needs to be well articulated and communicated by electronic means and remains a challenge in general-purpose EMR systems.

Purpose
This poster showcases our community-based participatory research to implement an EMR system to manage care provided in oncology clinics by integrating the workflow of radiation practices. The goal of our research is to explore the challenges and opportunities of using open-source tools to support an oncology clinic in a large teaching hospital, particularly in their radiation therapy process. Based on the user needs, we designed and developed a drawing module that would facilitate better communication and reduce errors.

Methods
We implemented the oncology terminology in the OpenMRS, the open-source EMR system. The global community of informaticians participated in customizing a dictionary that was suitable for oncology practices. We then involved interventional radiologists to further customize to add granular terms that are used in their practice. We observed the practice of hand-drawings, and the use of markers on X-rays that is used by radiology oncologists and technicians to communicate.

The drawing module was created by a Google summer of code intern to allow adding images and add pen-based input on these images. The images came from a PACS or RIS system into the EHR, with ability to make annotations and drawings on the images. These CT/X-ray images are also updated in a real-time basis on which the oncologist or radiologist can make changes that are reflected on the technician’s screen. The EMR system can also generate dose distribution curve based on a set of values that are entered by the oncologist. Over the next few weeks of treatment, based on the images that are recorded in the PACS, we also implemented a feature where dose distribution curves that can be adjusted by the oncologist in the drawing module and gets reflected on the technicians screen.

Preliminary results
Opportunities – The open-source community allowed the development of a quick terminology dictionary for oncology practice. The network of Informaticians provided suggestions for the creation of forms to generate the dose distribution curves. The development of the drawing module was done by the support of Google for open-source projects. Students participated in the community and developed tools that can be used by any implementation around the world.

Challenges – The limited capabilities of integrating OpenMRS with EBRT devices hampers direct management. Technicians are skilled users of EBRT devices, but not experienced in the use of EMRs. Device integration remains a challenge unless access to device APIs is available to developers of EMR system.
User-Centered Design of an Application to Aid in the Safe Return to Work of Injured Farm Workers

Andrea Mahnke, MS, Laurel Verhagen, BS, Bryan Weichelt, MS, MBA, PMP, Iris Anne Reyes, MPH, Will Ray, BA, Matthew Keifer, MD, MPH

(1)National Farm Medicine Center, Marshfield Clinic Research Foundation, 1000 N Oak Ave, Marshfield, WI 54449
(2)Biomedical Informatics Research Center, Marshfield Clinic Research Foundation, 1000 N Oak Ave, Marshfield, WI 54449

Background
Large animal farms are growing in size, increasing work task specialization and immigrant labor. Workers not only face inherent risks in the agricultural workplace, but are also introduced to significant dangers in these operations. Injuries in dairy and pork farms are common and are increasingly managed by primary care physicians. Yet, clinicians are often unfamiliar with the physical demands of farming and have little training and few resources to manage the safe return to work of injured workers. This project will develop a computer application designed for clinicians, working with patients, to guide safe return to work planning for injured workers in the dairy and pork industries.

Objective
We employed user-centered design methods to build an application to assist clinicians, physical therapists and occupational health therapists in translating physical restrictions into potential work task recommendations specific to an injured worker. The application has the potential to replace existing ink over forms and would result in more structured data, which helps make the data available for research projects. Due to the large population of Spanish speaking workers, the application’s interfaces and forms will be available in both English and Spanish. The flow of the new application starts with an industry, agriculture or other, entering job task physical demands into the system. Then when an injured worker is being assessed physical limitations will be entered by the clinician. Next the system will generate a list of potential tasks the injured worker may be able to do. The clinician and injured worker would then select tasks that are a match for their job. An output sheet would then be generated which would include physical limitations, as well as recommended tasks for the injured worker to take back to employer. The injured worker and employer would review the list and arrive at appropriate tasks for the worker to do while healing from injury.

Methods
This project employed an iterative user-centered design method on three primary end user types that interact with the system. These included employers, workers and the clinicians, including physical and occupational therapists. A usability analyst visited dairy farms to interview farmers regarding their experience with returning injured farm workers to work. Focus groups were also conducted with farm workers, some of whom had been through the injury and return to work process. Audio recordings were taken for all sessions; focus groups were also video recorded. All participants were compensated for their participation. Interviews and focus groups probed the understanding and interpretation of the existing Workers’ Compensation Report that is given to both farmer and worker by the clinician. The current form identifies physical restrictions for the worker, but does not make any recommendations regarding suggested tasks the worker may be able to perform while healing from injury. Interviews were also conducted with a variety of clinician roles that had experience with injured farm workers. In parallel with the interviews and focus groups, the team developed several iterations of a structured version of the form and a “patient friendly” output report. Patient friendly forms had a cleaner, less dense layout and included recommended work tasks. For both interviews and focus groups the participants were presented with the current form and a redesigned iteration of both the structured form, as well as a patient friendly form. Feedback regarding the alternate layout of the forms was collected. Qualitative analysis of interviews and focus groups was done using NVivo software. Areas for improvement were identified and implemented iteratively.

Results & Conclusions
Data collection and analysis ongoing. Valuable insights were revealed by focus groups and interviews that have helped to steer interface design of early application iterations.
The Process of Using Focus Groups to Inform Development
Jennifer A. Mallow PhD, FNP-BC1*, Laurie A. Theeke, PhD, FNP-BC, GCNS-BC1 Elliott Theeke1 and Brian K. Mallow, PMP, MCDBA2

Introduction

Used as an integrated tool, technology may improve the ability of healthcare providers to improve access and outcomes of primary care in rural populations (1). Incorporating input from the beginning stage of development to implementation of the intervention has the potential to enhance adoptability and sustainability in real-world settings. This poster reports the findings from focus groups aimed at evaluating a newly developed mHealth architecture called mI SMART (Mobile Improvement of Self-Management Ability through Rural Technology). The mI SMART platform combines multiple technologies including HIPAA compliant, web-based system of mHealth sensors and mobile devices that allows patients living in rural areas to perform self-monitoring, receive feedback in real time, attend eVisits for education, mental, and physical health from their home, and displays a record database to patients and providers. The creation of mI SMART is being guided by the model for developing complex nursing interventions (2).

Methods

In 2014 we completed focus groups in an academic, outpatient, and community setting. The approach for this study was developed using Krueger’s Focus groups: A practical guide for applied research (3). The focus groups were 60 minutes long. The facilitator provided a demonstration of the mI SMART platform. Directly following the demonstration, the following open ended questions were asked to each group: What do you think your biggest obstacle is when thinking about prescribing mHealth tools? As a patient yourself, what do you think your biggest obstacle is when thinking about using mHealth tools? What did you like best about the mI SMART platform? What would you like to see removed from the mI SMART platform? What would you like to see added to the mI SMART platform? Which outcome measures do you think would be most helpful to measure when treating patients with chronic illness? What outcome measures do you think are most important to patients? What else would you like to tell me about mI SMART? Lastly, the participants were asked to complete a questionnaire with demographic information and specific questions regarding the past, current and future use of mHealth tools. The field notes were entered into a Microsoft access database with the demographic information and responses to specific questions regarding the past, current and future use of mHealth tools. Several procedures were employed to maximize the transcription quality, and to ensure that quality standards were maintained (4).

Results

Both prescribing (N = 8) and non-prescribing healthcare team members (n=21) attended the focus groups. The majority were practicing for more than 20 years (44.8%) in an outpatient clinic (62%) for 20-40 hours per week (37.9%). Only 2 participants had used mHealth tools in the past. Providers identified perceived obstacles of patient use as ability, willingness, and time. System obstacles were identified as lack of integration, lack of reimbursement, and cost. Nineteen providers (65%) reported that they would definitely use this mHealth architecture in the future. The positive attributes of the developed system were: capability for virtual visits, readability, Bluetooth connectivity, user-friendliness, ability to capture biophysical measures, enhanced patient access, and incorporation of multiple technologies. Providers suggested increasing capability for biophysical and symptom monitoring.

Conclusion

Technology interventions have the potential to improve access and outcomes but will not be successful without the input of users. Findings from these focus groups are being used to inform continued development of the mHealth architecture prior our implementation of the system.

Responders and Nonresponders: Nurse Practitioner and Physical Therapist Personal Perceptions of Activity Monitors for Patient Use

Peggy J. Mancuso, Ph.D., RN, CNM, CNE, Sahiti Myneni, Ph.D., MSE
University of Texas School of Biomedical Informatics at Houston, Houston, Texas

Abstract
The purpose of this mixed-methods study was to explore personal perceptions of Nurse Practitioners and Physical Therapists regarding use of activity monitors as adjuncts to patient care. Reactions from a convenience sample of 23 participants pursuing doctorate education varied. Nineteen were positive for 14 weeks, but four became “nonresponders” at three weeks, a point when support may be needed for successful use. Most participants responded that these devices would be beneficial for some patient populations.

Introduction
Activity monitors, with associated smartphone applications and web pages, enable individuals to track activity, sleep patterns, and energy expenditure daily. The purpose of this study was to explore personal experience perceptions of Nurse Practitioners (NP) and Physical Therapists (PT) regarding the clinical utility, usability, and usefulness of an activity monitor (Fitbit® One (clip) and Force (bracelet) for patient populations. Such an understanding will allow utilization of these devices as effective components that form the core of patient-engaging care delivery processes.

Methodology
The following research questions were addressed: What are NP and PT personal experiences with daily activity monitors regarding utility, usability, and potential usefulness in patient populations? How do these perceptions change over time and with consideration of the existing evidence? A convenience sample of 9 NPs and 14 PTs students was accessed from practitioner students pursuing practice doctorate education. Each participant received a Fitbit® One or Force at the beginning of the semester. Participants were assessed weekly via voluntary discussion boards regarding ease of use and potential for devices to improve or worsen patient outcomes. Participants were requested to forward weekly activity reports provided by Fitbit® to investigators. At the end of the study period, participants responded to online surveys about the value of health informatics for patient care. One device used in the study, the Fitbit® Force was recalled during the study. This product recall enriched participants’ qualitative responses. Triangulation, rich description, and peer review ensured rigor of analyses.

Evaluation Results
There were 19 active NP and PT participants and 4 inactive NP participants. Inactive participants become “nonresponders” with minimal postings at approximately three weeks after initiation. Several themes emerged from qualitative analysis (see Figure 1): (a) usage timeline, (b) self-realization, (c) device relationship, and (d) potential use in patient populations. Five stages characterized the usage timeline: new user, technological difficulty, honeymoon period, habit formation, and habituated user. Those who expressed enthusiasm tended to use more device features (e.g., recording sleep) over time. Multiple users noted self-realization and surprise at activity levels. For example, “busy was not the same as being active.” Active participants described the device as a “motivational partner” that provided “validation.” Participants also described “doubts about accuracy” and “lack of trust.” They were frustrated with “lack of (technical) support” and “expense of the device.” Some participants expressed depression about the recall of the Fitbit® Force (e.g. “I miss my Force terribly”). The providers’ perceptions of potential use of these devices in patient populations varied by professions, with PT practitioners recommending generalized patient use and NPs proposing use for specific populations only. Both professions noted that activity monitors would be most successful with “motivated patients.”

Conclusions
This study explored current self-help technologies (activity monitors) from the perspectives of practicing PTs and NPs who were pursuing practice doctorates. Several socio-technical factors are found to play a role in the adoption of these technologies. Of interest, was the three-week period that marked the time that some NPs became “nonresponders” and ceased voluntary personal use of the monitor. This period could represent an important point when additional support would facilitate continued future use of the activity monitor.

ICan’tCount: a mobile app for helping children with dyscalculia
Andrea Marchesini¹, Vincenzo Maurelli¹, Siria Pantano¹, Giuseppe Vacante¹, Marilena Coniglio², Gianluca Palermo¹, Vittorio Tauro¹, Agostino Accardo³, and Sara Marceglia, PhD²,³
¹ Dipartimento di Elettronica, Informazione e Bioingegneria, Politecnico di Milano; ² Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ³ Dipartimento di Ingegneria e Architettura, Università degli Studi di Trieste, Trieste, Italy;

Introduction
Dyscalculia is a specific learning disorder that affects 1.2% of 7.1 million pupils in Italy and is usually recognized by the teachers who send the potentially affected child to a specialized neuropsychologist for diagnosis. Dyscalculia diagnosis relies on a paper-based test administered by the neuropsychologist. However, the paper-based test requires medical supervision, thus leading anxiety in the child. To avoid this, we designed and developed an app to support both the neuropsychologist and the child during the screening test and, after that, during rehabilitation.

Methods
Working together with the Pediatric Neuropsychology Unit of the Policlinico Hospital in Milan, we designed and developed an iOS application for iPad based on the AC-MT test, released by Erickson publishing¹. The App was designed to allow the clinician to see the results of the test and to assign specific exercises, in order to support parent’s rehabilitation. Parents were also considered as users and were allowed to both receive information on the disease and monitor the improvements of their child. The App was tested by three independent neuropsychologists during their normal ambulatory activity.

Results
The App, named I Can’t Count, includes five sections: ‘Gioca’ (Play) is the section in which the child completes the test; ‘Esercizi’ (Exercises) allows improving calculation skills through exercises assigned by the clinician, ‘Risultati’ (Results) shows the results of the rehabilitation activity, and in ‘Area Riservata’ (Doctor's Reserved Area) the clinician assigns the exercises to the child. The App, developed with an Italian graphic designer, displays virtual pages to make calculations as on a paper sheet. The three neuropsychologists used the App for one week in their clinical practice and reported that it helped the diagnostic process, supporting the children to easily and smoothly complete the AC-MT test. The children had no problems in understanding how to perform the test, thus fastening the screening visits.

Figure 1. Representative snapshots of iCan’tCount.

Conclusions
Even though still in a prototype version, our application could be a starting point for improving the diagnosis and rehabilitation of dyscalculia. The app was designed to have a user-friendly interface and to be used by doctor, children and their families.

Qualitative Analysis of Responses to a Questionnaire via an EHR Patient Portal

Elizabeth A Marshall, MD, MBA, Suparna Qanungo, PhD, Jihad S Obeid, MD, James C Oates MD, Melissa L Habrat, BA, Bob Warren, MD, PhD, MPH, Leslie A Lenert, MD, MS
Medical University of South Carolina

Abstract: Obtaining and updating patient preferences for participation in research can be cumbersome for both patients and clinical investigators. A patient portal to the electronic health record (EHR) provides a suitable venue for patients to indicate and manage their preferences. However the process may be confusing at times to patients. As a result unplanned questions and concerns may arise. We report on the qualitative analysis of patient responses thus far.

Problem addressed: Low recruitment into clinical trials historically has been a problem, resulting in incomplete study recruitment and/or increased costs to study sites. Increasing the number of volunteers for potential participation in research helps address this problem. Patients seen at a hospital or clinic typically have no means of indicating their interest in research participation. However it is the responsibility of health organizations to collect the permissions from patients who wish to be contacted for participation in future research studies, especially if they can be matched to EHR phenotypes. The Medical University of South Carolina (MUSC) has historically recorded patient research preferences via a paper consent form completed at the time of registration. Due to issues such as transcription error and lack of accessibility to update research preferences, a new method was developed.

Informatics intervention: This solution involves the use of a questionnaire sent via the EHR patient portal (Epic MyChart). MyChart had only been used for clinical correspondence within the hospital system. This was the first attempt involving research. During the implementation of this new method for research preference collection, a new project evolved involving the qualitative analysis of the replied responses to the questionnaire.

Methodology and evaluation: A questionnaire with various parameters to address participant’s research preferences were designed and distributed via MyChart. Data was collected from the onset of the first message received to the MyChart questionnaire between December 15, 2014- February 15, 2015. Interestingly, a total of 1108 e-mail messages were received via MyChart. These emails were unplanned responses to the questionnaire. They could be categorized into two groups: first, those who completed the questionnaire and sent an e-mail response; and second, those who just sent an e-mail response with no questionnaire. In order to do a qualitative analysis of all the messages/responses, a random sampling will be done such that 25% of the 1108 messages will be selected in total. Since messages came in at various sections of the day, an even sampling of responses from three time frames of Morning (4am-noon), Afternoon (noon-8pm), Evening (8pm-4am) will be taken. A traditional content analysis will be done comparing responses of those individuals that completed the questionnaire and those that did not; we will focus on the areas of comprehension, access to care, computer/technology, and insurance. With this approach, our goal is to capture all the diverse perspectives of the patients as well as identify barriers and concerns of using a patient portal to indicate and manage research preferences. The primary outcome of this study is to assess patient responses towards a research questionnaire in order to improve MyChart operations.

Conclusion: Patient-centric care approaches leveraging remote monitoring and informatics support represent a promising approach to maintaining patient satisfaction and clinical quality while reducing overall care costs. We anticipate that this study will contribute to the further evaluation of addressing some of the barriers of the use of a patient portal such as MyChart for future resolution of this increasingly important approach to improve recruitment into clinical trials.

Bring Your Own Device: From PDA To Smart Mobile Devices
Karen Martinez, BSN, MSc; Karen L. Courtney, PhD, RN; Elizabeth Borycki, PhD, RN & Noreen Frisch, PhD, RN, FAAN,
University of Victoria, Victoria, British Columbia, Canada

Introduction
The mobile nature of healthcare made the concept of mobile technology use attractive in the clinical setting. Personal mobile devices use in the clinical setting generates perceived concerns and benefits. Over the last thirty years, the types and capabilities of mobile technologies have changed significantly; however some benefits and concerns have remained constant despite the changes in technology. This poster will present results of a literature search done to describe and compare the use of electronic personal devices in the healthcare environment from the historical Personal Digital Assistant (PDA) to the modern smart mobile devices (smartphones/tablets). The poster will also include the similarities and differences in perceived concerns and benefits over time and extrapolate lessons that may apply to the next generation of mobile technologies. Next generation mobile technologies will continue to move forward. There is a need to address the benefits and risk of the use of these personal technologies as it can have an impact on the practice of healthcare professionals and patient care.

Methods
A literature search was performed (2000–2015) using PubMed, Google scholar, and Google. Grey literature (Google) was included as we were interested in subjective perceptions of benefits and concerns and empirical literature was limited when the devices were first introduced into the healthcare environment. Specific keywords for mobile devices included: “Personal Digital Assistant devices” or “PDA” as used in a “clinical setting” or “hospital” (2000-2008) and “BYOD [Bring Your Own Device]” or “tablet/iPad” or “smartphones” in “clinical setting” or “hospital” (2008-2015).

Results
The principles behind the past use of PDA devices and the current use of smart handheld devices, when compared, are quite similar. PDAs and smart mobile devices provide real-time access to information by providing decision support, education, and data collection at the point-of-care. PDAs enabled healthcare professionals to organize their contacts, calendars, but also access journals electronically. Unique to smart mobile devices was their use as a replacement for multiple devices health professionals previously carried.

Both types of devices were recognized for the benefits of convenience, mobility, and efficiency. Consistent concerns with both devices were privacy and security. Further, there was also a perceived issue with productivity that varied with the different types of devices over time.

Conclusions
The consumerization of these powerful handheld computerized devices has resulted in their affordability and the use of these personal mobile devices in the workplace is visible to many. The core benefits and concerns noted above seem stable across the different technologies. These factors are likely applicable to future personal technologies that may be brought into the healthcare environment by healthcare professionals. Healthcare organizations need to address integration of such devices to meet practice needs safely.
Simultaneous optic disc and macula detection using template matching

Maria A. Martínez-Castellanos, MD1, M. Elena Martínez-Pérez2, Tzolkin Garduño-Alvarado2, Luvia Rodríguez-Quíñones3, Samantha M. Salinas-Longoria1

1Asociación para Evitar la Ceguera en México I.A.P. Hospital "Dr. Luis Sánchez Buldnes", México; 2Institute of Research in Applied Mathematics and Systems, UNAM, México.

Abstract- Automatic computerized segmentation of optic disc (OD) and macula (MC) is an everyday need for clinical applications. Our algorithm achieves such a task by means of cross correlation of a template with the image. It performs a k-fold cross validation loop. Each of its iterations is composed of a training and a validating stages. Results are reported on 37 fundus images obtained from a diabetic retinopathy screening program.

I. INTRODUCTION

Diabetic Retinopathy (DR) is a chronic disease that affects the eye. More specifically, it is the manifestation of diabetes mellitus in the eye retina. Fundus images are used by ophthalmologists to trace and locate lesions caused by DR. The OD is a retinal area mildly oval with the major axis in the vertical position. Its mean area is 2.7 mm2 and its horizontal radius of approximately 1.8 mm. A variety of methods for the location and segmentation of the OD have been implemented, [1], [2], [3], to mention some. The MC is an oval area in the center of the retina. It is located 3 to 4 mm (15 degrees) from the OD, slightly downward, and between the major temporal vascular arcades. Some of the methods used for MC location can be found in [4], [5], [6].

II. MATERIALS

The set of images used in this paper consists of 37 images corresponding to either left or right eyes from patients suffering from diabetic retinopathy, images being captured with a Carl Zeiss FF450 plus IR fundus camera, the field of view angle used is 50 degrees and the size of the images is 489*647 pixels. They have had the OD and MC structures segmented by two licensed ophthalmologists.

III. ALGORITHM

Before making the computation of the process, a preprocessing stage is performed. Afterward, a kfold cross validation is executed on the images. A loop of k iterations is carried out, in each iteration k-1 of the subsets are used for training, while the remaining one is used for validation. Before running the algorithm, a noise reduction median filter is applied to the green band of the images, kernel size being 5*5. A polynomial approximation of the background illumination was made using a basis of discrete orthogonal polynomials, [7], [8], the polynomials used for the present approximation were of third degree. Next, the approximation was subtracted from the original image.

The training step of each iteration receives images, output being a grayscale template of the region where the OD and MC are located along with its corresponding coordinates (x,y) and the template where it belongs. The coordinates represent the center of a rectangular region the size where the OD and MC are located in the image.

IV. RESULTS AND CONCLUSION

The evaluation of the algorithm is a process with which the optimal k for the fold is chosen. Optimal k is chosen as the one that yields the least error. The error in this case is the distance between manual segmentation and the result of the algorithm. Two databases where calculated, a private one consisting of 37 images and the DRIVE dataset[9] consisting of 40 images out of which 35 were used given 5 did not contain OD and MC at the same time. On both datasets optimal k=3 was obtained. Our results showed 100% optic disc centers located within the OD area and 90% macula centers located within the MC area. The results in the DRIVE dataset showed 97% of the OD centers located within the OD area and 77% of MC centers located within the MC area.

Abstract: This poster describes the study design for an innovative, pragmatic randomized controlled trial to evaluate the impact of a personalized, web-based patient portal, Inpatient myNYP. The federally funded trial is being conducted with cardiology patients at NewYork-Presbyterian Hospital/Columbia University Medical Center. The purpose of the intervention is to improve engagement and satisfaction in hospital patients.

Introduction: Patients who are better informed and more engaged in their healthcare have higher satisfaction and better health outcomes. While patient engagement has been a focus in the outpatient setting, strategies to engage patients while they are inpatient have been lacking. Patient-centered care can be improved in the hospital visit through better information management practices. We developed Inpatient myNYP, a personalized, dynamic web-based patient portal where patients can view members of their care teams, track current and historical vital signs, review their documented hospital medications and allergies, document pain scores, record personal notes, and send questions and comments to their care team members (Figure 1).

Methods/Results: We are conducting a pragmatic randomized controlled trial to evaluate the impact on patient engagement and satisfaction of giving patients access to Inpatient myNYP via tablet computers (Apple iPads) in 426 inpatient cardiology patients at NewYork-Presbyterian Hospital. Participants are randomized to one of three groups: 1) control group, 2) iPad with basic functionality, and 3) iPad with Inpatient myNYP. To date, 75 participants have been enrolled and randomized in the trial. We hypothesize that participants in arms 2 and 3 will have increased satisfaction compared to the control group, due to entertainment options provided by the tablet. We also hypothesize that participants in arm 3 will have higher patient engagement due to access to Inpatient myNYP. The primary outcomes of this trial are patient satisfaction (measured using a modification of Telemedicine Satisfaction and Usefulness Questionnaire [TSUQ]), and changes in patient engagement (measured by the Patient Activation Measure [PAM]). The secondary study outcomes include rate of changes to medication orders (e.g., if changes are requested by the patient), changes to length of stay, the rate of refusal by patients to accept medications, and the number of adverse events that occur during the hospital stay. The PAM score is collected at study enrollment, and all other outcomes, including the follow-up PAM score are collected between days 3 and 5 of the hospital admission.

Conclusion: We hypothesize that the use of the inpatient portal will identify and address patients’ information needs, enhance patient engagement, and improve satisfaction.

High Level Architecture and Evaluation of Patient Linkages for READY - An Electronic Measurement Tool for Rheumatoid Arthritis

Puneet Mathur, MS, MBA1; Leslie A. Southern, BS1; Aseem Bharat, MBBS, MPH2; Shunchao Wang, MS1; Chris Heckler, BS, PMP1; Omkar Lele, MS, MBA1; Peter J. Embi, MD, MS1; Jeffrey R. Curtis, MD, MS, MPH2
1Department of Biomedical Informatics, The Ohio State University, Columbus, OH
2University of Alabama at Birmingham, Birmingham, AL

Abstract
RhEumatoid Arthritis Disease activity (READY) is an electronic measurement tool for tracking Rheumatoid Arthritis (RA) to help physicians render better clinical care. It collects data using validated instruments to score longitudinal patient reported outcomes (PROs). We here describe the high level architecture of READY tool in a multi institution environment operating on the cloud platform along with evaluation of a mechanism for generating a hashed identifier for patient linkages internally and across external system.

Introduction
Tracking patient reported outcome (PRO) data is increasingly important to clinical research and healthcare improvement. The READY application captures PRO data via various generic and disease-specific instruments. Responses to these instruments allow calculation of scores that measure functional status and RA disease activity. One of the major goals for developing this tool was the ability to store and retrieve patients’ past visit occurrences and visually plot PRO data trends.

Methods and Results
The READY platform functions in a multi institution environment with multiple physicians’ office sites operating under a site ID. The application logic is provisioned by web services deployed over a centralized cloud platform (Figure 1). The challenge of leveraging cloud platform along with fulfilling HIPAA requirements for purposes of patient record linkages was met by creating a one way hashed patient identifier (using a SHA-256 function) from a combined string of selected Personal Identifying Information (PII) data. We evaluated various combinations of PII data elements against approximately 3 million patient records at The Ohio State University Wexner Medical Center in order to achieve the highest positive predictive values and to minimize collisions, or false positives. Results are summarized in Table 1 and show that first 2 letters of first and last name, date of birth, sex, middle initial & physician’s National Provider ID (NPI) number was able to link patients with very few collisions (0.15%).

Conclusion
The architecture and evaluation of patient record linkages has laid the foundation for implementing the application in a multi-site setting. This also opens new opportunities for interacting with external systems easily where linkages between health systems and patient registries (e.g. PCORnet) is desirable using a common hashed patient identifier.

Clinician Evaluation of Clinical Decision Support Alert and Response Appropriateness

Allison B. McCoy, PhD1,2, Eric J. Thomas, MD, MPH3, Marie Krousel-Wood, MD, MSPH1,2, Dean F. Sittig, PhD3
1Tulane University, New Orleans, LA; 2Ochsner Health System, New Orleans, LA; 3The University of Texas Health Science Center at Houston, Houston, TX

Abstract
Effectively evaluating the appropriateness of clinical decision support (CDS) alerts and responses is critical to improving patient safety through health information technology. Using a REDCap data collection tool, clinicians adjudicated the appropriateness of CDS alerts and responses. Of 397 alerts evaluated, 98.7% were overridden, 38.3% were appropriate, and 97.2% received appropriate responses. Further research is warranted and underway to identify predictors of inappropriate alerts, improve alert specificity, and reduce alert fatigue.

Introduction
Computerized alerts that warn clinicians about drug interactions or provide dosing guidance are commonly implemented forms of clinical decision support (CDS) to improve patient safety. Alert overrides can hinder provider effectiveness and result in adverse patient outcomes. Detailed evaluation of the appropriateness of alerts and clinician responses is necessary; however, few have performed these evaluations.

Methods
Based on a previously described alert evaluation framework, we developed an assessment tool using REDCap to facilitate reviews by clinicians in adjudicating the appropriateness of CDS alerts and responses. We extracted log data from the electronic health record (Allscripts Enterprise EHR) and imported alerts from 100 randomly selected patients who received an alert between January 1 and July 1, 2013 into REDCap to populate these fields prior to clinician reviews. Clinician reviewers then indicated whether the alert and response were appropriate, why the alert was inappropriate (if applicable), and what response(s) would have been appropriate. Each alert was reviewed initially by two clinicians, and a third clinician reviewed alerts when there was a disagreement. We report descriptive statistics on relevant alert, patient, clinician, and medication characteristics.

Results
The clinicians evaluated 397 medication alerts. Of these alerts, 392 (98.7%) were overridden. Clinicians adjudicated 152 alerts (38.3%) as appropriate; 149 appropriate alerts were overridden. Clinicians also adjudicated 386 (97.2%) of alert responses as appropriate; 381 (98.7%) of appropriate responses were overrides, although in 4 cases the medication was not actually ordered, and in other cases clinicians performed additional care, including removing duplicate orders, decreasing doses, ordering monitoring, and documenting awareness of potential interactions. Other causes for appropriate overrides included out of date medication and problem lists, history of patient tolerance despite reported allergies and interacting conditions, and low alert specificity (i.e., alerts about pregnancy contraindications for all women of childbearing age). Trends were similar for all alert types (i.e., drug-drug, drug-allergy, drug-dose, and drug-condition). The median numbers of historical patient alerts, medication orders, and recorded problems were lower for appropriate alerts than inappropriate alerts (16.5 vs 24, 7 vs. 10, and 17 vs. 18 respectively).

Conclusion
We identified low rates of appropriate alerts; most clinician responses to alerts were appropriate, though these were often justifiable overrides or additional provision of care. Poor maintenance of up-to-date patient charts and non-specific alert criteria contributed to inappropriate alerts. High rates of inappropriate alerts that merit overrides by clinicians may have a negative impact on patient care and should be eliminated. Further research is warranted and underway to identify significant predictors of inappropriate alerts, improve alert specificity, and reduce alert fatigue.

Stratification of Risk for Fall Resulting in Hospital Readmission through Medication Side Effects Profiles

Thomas H. McCoy, Jr., MD\textsuperscript{1}, Victor Castro, MS\textsuperscript{1,2}, Roy H. Perlis, MD, MSc\textsuperscript{1}
\textsuperscript{1}Center for Experimental Drugs and Diagnostics, Massachusetts General Hospital, Boston, MA USA; \textsuperscript{2}Partners Research Computing, Boston, MA, USA

Abstract

Fall related injury is a major source of morbidity and mortality. Stratification of fall risk is an important step towards targeted intervention. Epidemiological data suggest that dizziness, syncope, hypotension, and confusion contribute to a patient’s fall risk. Off-target effects of medications with these adverse effects may themselves impart detectable fall risk. Testing this hypothesis in a statewide database, we find that inclusion of medication side effects enhances predictions of hospital readmission due to falls.

Introduction

Falls-related injuries are important sources of morbidity and mortality\textsuperscript{1,2}. Patients’ physiological states, including weakness, dizziness, vertigo, confusion, and hypotension are implicated in the majority of falls\textsuperscript{3}. Off-target effects of medications may induce or exacerbate such states. The desire to target fall prevention efforts has motivated risk stratification attempts; however, to date these attempts have required evaluations that are difficult to translate into practice\textsuperscript{4}. Prior work suggests medication side effects can identify biological consequences of interest\textsuperscript{4,5}. This is appealing, as medication lists are readily available for translation to practice. The work presented here is an attempt to extend this method to enhance predictions of fall risk using side effect profiles in a large, heterogeneous clinical population.

Methods

Diagnostic and sociodemographic data from a statewide claims database were used to derive a logistic regression model of hospital readmission for injury related to fall at 180 days following discharge from the index hospitalization. This model was augmented with a medication side effect feature calculated using previously published medication side effect profiles that were hand annotated as predictive of fall risk\textsuperscript{5,6}.

Results

Of 193,000 identified hospital discharges, 1,900 resulted in readmission following falls. Older age at admission, index admission through the emergency department, higher age-adjusted Charlson Comorbidity Index, and higher calculated side effect profile were independently associated with hazard for fall after adjusting for sex and number of medications prescribed. This model resulted in an AUC of 0.72 for prediction of fall within 180 days of discharge.

Conclusion

Medication side effect profiles available in previously published databases can be used in conjunction with prescriptions and diagnostic claims data to enhance prediction of falls within 180 days of hospital discharge.

A Taxonomic Analysis of Programming Errors in Electronic Health Records (EHRs) which Lead to Clinical Decision Support Malfunctions

Dustin S. McEvoy, BS¹, Salman T. Hussain, BSc², Thu-Trang T. Hickman, MPH², Dean F. Sittig, PhD³, Adam Wright, PhD¹,²,⁴
¹Partners Healthcare, Information Systems, Wellesley, MA; ²Brigham & Women’s Hospital, Boston, MA; ³University of Texas Health Science Center, Houston, TX; ⁴Harvard Medical School, Boston, MA, USA

Introduction

With expanded implementation of clinical decision support (CDS) systems in EHRs has come increased concern over patient safety issues that may result when CDS functions improperly.¹ Cataloging and learning from these issues is essential to patient safety and the effectiveness of CDS. While a number of efforts to investigate HIT related safety issues exist, limited work has been done to explore CDS specific issues and their causes.² Given this, we sought to catalog CDS types prone to failure and the programming errors leading to these failures in the EHR.

Methods

We reviewed the Team Coordination System (TCS) database at Partners Healthcare which contains over 100,000 reports cataloging IT related dialog between analysts, developers, engineers and end-users of the Partners EHR. To identify CDS related reports, we queried the database for resolved issues containing terms such as “alert” or “DDI”. Reports related to CDS were analyzed to determine the CDS type and programming error involved. CDS type was classified using previously developed taxa³ while programming error type was classified using a subset of the taxa presented by Ko and Myers.⁴ Reports were classified with a single programming error type and up to 2 CDS types.

Results

Of the 4,941 reports meeting our search criteria, 1,500 have been reviewed to date and 93 (6%) distinct reports have been deemed related to CDS. The majority of these reports have involved point of care alerts and reminders (63%), while reports related to medication dosing support (18%), order facilitators (12%) and workflow support (12%) were also frequently observed. The types of programming errors observed varied more considerably. Among the reports where programming error type could be determined from the dialogue, omission errors (24%), trivial typos (19%) and imperfect design specifications (18%) were most common. Programming error type varied with CDS type, but there was insufficient data to determine a clear relationship between the two.

Conclusion

This is the first catalog of the types of CDS prone to failure and the programming errors leading to these failures in the EHR. Initial observations indicate that programming errors are major barriers to the proper implementation of CDS. Various programming error types were observed across the reports, suggesting that careful CDS specification development and intervention testing are essential in preventing patient safety issues. While the majority of the reviewed reports were related to point of care alerts and reminders, this may be due to bias introduced by the search terms used to extract these reports, which focused primarily on descriptions of this type of CDS. We are expanding on this work to further investigate causes, types, and inter-relationships that result in CDS malfunctions.

Partnering to Develop a Service-based CDS System for Public Health Reporting Specifications

Sunanda McGarvey, CBAP, CSM; Denisha N. Abrams, Janet Hui, MPH; Laura Conn, MPH; Catherine Staes, MPH, PhD; and the RCKMS Team

1Northrop Grumman Information Technology, Atlanta, GA., 2Council of State and Territorial Epidemiologists, 3Centers for Disease Control and Prevention, 4Department of Biomedical Informatics, Univ. of Utah, Salt Lake City, Utah

Background
In the US, selected conditions must be reported to public health authorities by physicians, hospitals, and laboratories to control disease and monitor population health. Currently, reporters must manually review various sources to determine reporting criteria, and often clinicians are unaware of reporting requirements (1). The Reportable Condition Knowledge Management System (RCKMS) project, supported by the Centers for Disease Control and Prevention and the Council of State and Territorial Epidemiologists, is focused on developing an infrastructure to allow public health authorities to author their logic and present reporting criteria in a human-readable and electronic format. The objectives of the project is to: a) describe variation in reporting specifications for 4 reportable conditions across 11 jurisdictions; b) define logic to represent the reporting specifications as machine-processable rules in a public health decision support system; and c) collaborate with a healthcare enterprise to use the public health decision support system to determine if a case is reportable to public health.

Methods
We convened a workgroup of public health experts from seven states (CO, DE, IL, NY, UT, VA & WA) and four counties (Houston, New York City, Southern Nevada & San Diego), subject matter experts, and experts from Intermountain Healthcare, and HLN Consulting, LLC weekly from Nov 2014 through July 2015. The workgroup assessed variability in reporting criteria, identified areas for harmonization and simplification, and proposed a default set of logic for each condition. In a parallel effort, vocabulary subject matter experts convened twice a week to draft standardized value sets and rules algorithms to support the default logic. To manage the reporting specifications and generate machine-processable rules based on the logic, the team worked with HLN Consulting, LLC (the Clinical Decision Support [CDS] implementers). Informaticians from Intermountain Healthcare engaged as an entity required to report to public health. They provided insight from the inpatient, outpatient, and laboratory perspectives. Weekly meetings were held with HLN Consulting, LLC and Intermountain to define implementable technical approaches that supported public health reporting requirements and moved existing manual text-based processes to automated machine-based processes. An interface for public health professionals to author reporting logic is being designed, and the logic implemented using the service-based CDS infrastructure will be tested and validated.

Results
Among the jurisdictions involved, we identified criteria with varying levels of specificity and different terms to represent common criteria. For tuberculosis alone, thirteen variations of clinical criteria could be rolled up under 6 common criteria. Similarly, for pertussis, the public health practitioners were able to harmonize and agree on a proposed set of logic that includes sixteen criterion (i.e., clinical, lab, epi, demographic criteria) grouped into 6 sets of logic. Similar results were achieved from harmonization of Chlamydia and Lead criteria. HLN, LLC is translating the sets of logic into computable rules that Intermountain will access through a service-based CDS infrastructure to determine if a report should be sent to public health, to which jurisdictions it should be sent, and what it should data elements it should include. The poster will include up to date progress on the development and testing of RCKMS.

Conclusion
Variation does exist among jurisdictions, however jurisdictions can reduce variability and logic can be implemented in a service-based CDS system. Collaboration across public health, and with healthcare, is vital to making automated case reporting a reality.
Visualization of Laboratory, Vital, Precaution and Patient Status Data to Optimize Time on Task and Use Related Hazards

Ray McKelvy,1 Nathan C. Gonzalez,1 Karol L. Fleming JD, MBA,1 William B. Webb BSPH,1 MBA, Robert L Shapiro MD, MSCI1,2

1 MEDarchon, Inc. 113 29th Avenue South, Nashville, TN 37212
2 Cardiovascular Division, Washington University in St. Louis School of Medicine, 660 S. Euclid Avenue, St. Louis, MO 63110

Background: Handoff incorporates a vast amount of data which is subject to use related hazards.1 Negating use related hazards and reducing time on task are significant factors for adoption. This study sought to test the time to comprehension, use related hazards and user satisfaction associated with various methods of visualizing handoff data.

Methods: Doctors and nurses with at least two years of clinical experience were selectively recruited based upon their role, specialty and patient population. After informed consent, subjects were presented with data visualizations for a sick patient and a healthy patient and asked to identify the healthy patient as quickly and accurately as possible. Visualizations tested included four chronological displays of lab and vital data, four displays of current and trend data ways of organizing laboratory findings, and two ways of presenting precautions and patient status (condition, airway, ambulatory, etc.). The order of the visualizations and placement of the sick vs. healthy patient was randomized. For each category, an electronic medical record visualization served as the control. A study administrator recorded and graded responses. Descriptive statistics and the Z test were used to summarize the findings. Results: 23 of 24 recruited subjects completed the study. Table 1 shows the mean time to comprehension, total errors and user preference for various graph formats tested, while Table 2 shows the same for the “graph-plus” format. There was no statistical difference in time to comprehension for organizing labs by the test type (p=0.651) or result type (p=0.412). Visualizing patient precautions (3.90 vs. 4.88 s, p=0.206) and status (4.01 vs. 7.39, p=0.053) with icons trended toward decreasing time to comprehension but did not reach significance. 78% and 61% of participants preferred the icon visualizations for precautions and status, respectively. Conclusion: This study has shown that the method of visualizing handoff-related data can reduce time to comprehension without negatively impacting use related hazards.

Born to Lose (the Call): Date of Birth Errors in Patient Identification in an Automated Adverse Drug Reaction Call System

Jeffrey Medoff, BA1; Alejandra Salazar, PharmD1; Elissa V. Klinger, MS1; Japneet Kwatra, BS1; Mary Amato, PharmD, MPH1,3; Patricia Dykes, PhD1; Jennifer S. Haas, MD1,2; David W. Bates, MD, MSc1,2; Gordon Schiff, MD1,2

1 Division of General Internal Medicine and Primary Care, Brigham and Women’s Hospital, Boston, MA; 2 Harvard Medical School, Boston MA; 3 MCPHS University, Boston MA

Introduction

Interactive Voice Response Systems (IVRS) have emerged as a method of reaching out to large numbers of patients in a cost efficient manner.1 We implemented IVRS for proactive identification of symptoms that may represent adverse drug reactions (ADRs). IVRS usability may be complicated by technological failures, operational challenges, patient acceptance or confusion with using this technology. One challenge, ensuring confidentiality, required that IVRS correctly identify the targeted patient. Using date-of-birth (DOB) verification is one approach we have used, but such a method can introduce unexpected complexities. After encountering various issues using DOB patient identification, we analyzed our experience to better understand reasons for IVRS DOB failures with the aim to improve system user-friendliness and response rates.

Methods

We implemented a randomized controlled trial to screen patients for adherence and ADRs associated with newly prescribed medications. After agreeing to participate, patients were asked to verify their DOB. Instances of unsuccessful verification (“DOB errors”) triggered an alert to research staff members, who manually reviewed the recording of each encounter. Errors were coded as one of three types: 1) patient response did not match DOB in the electronic health record; 2) response was inconsistent with format required; or, 3) response not correctly captured by voice recognition (background noise, delayed response). Some errors represented multiple types. DOB errors resulted in call termination (to protect against surveying unverified patients). Initially, DOB verification requested the entire date, but we later [pause]. Because high DOB-error rates continued, we reverted back to whole date format, allowing calls to proceed regardless of IVRS-DOB verification and instead had research staff manually confirm DOB for each patient.

Results

Overall DOB error rate was 34.0% (235 total errors for 691 patients who agreed to participate) with the majority (61.7%) due to inconsistent format. Surprisingly, patients experienced DOB errors at similar rates when prompted for whole date or sequentially (19.9% and 22.9%, respectively). Finally, when calls were allowed to continue without IVRS DOB verification, DOB error rates increased (44.1%). DOB error rates for Spanish-speaking patients (57.6%) were higher than English-speaking patients (30.1%).

Conclusion

We found high rates of technical DOB errors disqualifying large numbers of willing participants. The leading cause of DOB-errors was patient difficulty in comprehending and adhering to structured IVRS DOB verification format, with non-English speaking patients experiencing higher error rates. Restructuring IVRS prompts to parse birthdates into separate month, day, and year fields unexpectedly did not improve data capture. Requiring multiple attempts did result in increased success rates but not sufficiently to overcome this problem. More thorough pre-implementation piloting is warranted to ensure effective and equitable usability of such systems.

Exploring Gaps of Family History Documentation in the EHR

Saeed Mehrabi, PhD Candidate¹, Maya S. Safarova, MD, PhD², Iftikhar J. Kullo, MD², Hongfang Liu, PhD¹
¹Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA; ²Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN, USA

Abstract

In the era of precision medicine, accurately identifying familial conditions is crucial for providing target treatment. In this work, we studied the documentation of family history of stroke in clinical notes and compared it with patient-provided questionnaire (PPI). The agreement between patient-provided information and clinical notes on absence of family history information in PPI was higher compared to its presence.

Introduction

It has been shown that a wide range of adult conditions such as diabetes, cardiovascular diseases, Alzheimer’s and cancers have hereditary roots. Accurate family history information can be very helpful in precision medicine that tailors the treatment to the individual characteristics of patients.

Material and Methods

We have selected 27998 with family history of stroke or transient ischemic attack (TIA) and also retrieved their relevant PPI forms. We used our previously developed rule based NLP algorithm to extract family history information and associate family members and diagnoses¹.

Results:

The agreement between PPI and medical records was evaluated by randomly selecting 25 patients who reported having family history of stroke/TIA in their PPI form and 25 who did not. The positive and negative agreements are 0.653 and 0.7384 respectively.

Table 4. Positive and negative agreement measurements of stroke mentions in PPI forms and medical records

</tr>
</tbody>
</table>

We also evaluated our NLP performance by randomly selecting 100 sentences. There were 19 incorrect instances in 100 sentences resulting in accuracy of 81% of the NLP system. Majority of these errors (15 out of 19 or 79%) were due to incorrect family member associations.

Conclusion

We have identified that there are significant gaps in the family history documentation for making the correct diagnosis of familial conditions. Adequate family history information including detailed information such as affected family members and their social history, age of disease onset, and specific information regarding the disease in question are crucial.

Development of a Novel Application for Home Management of Chronic Low Back Pain

Brittany L. Melton, PhD, PharmD¹, Hannah J. Kevern², Jenna M. Stones², Neena Sharma, PT, PhD²

¹University of Kansas School of Pharmacy, Lawrence, KS; ²University of Kansas Medical Center, Kansas City, KS

Abstract

The objective of this project is to develop and test an iPad application for home-based therapy of chronic low back pain. Up to twenty patients will utilize the application instead of in-person physical therapy for six weeks. The application educates patients on pain physiology, fear avoidance, exercises, and pain management options. Patients will complete the Computer System Usability Questionnaire to assess usability, as well as questionnaires to evaluate changes in fear avoidance and pain control.

Introduction

Low back pain (LBP) is the second leading cause of disability in the United States, costing an estimated $560-635 billion annually, and the incidence is increasing.¹ ² Exercise therapy is the standard of care for chronic LBP but less than half of patients have been prescribed exercise, and only 30% have seen a physical therapist.³ ⁴ At the same time, exercise therapy does not address the psychological factors associated with chronic pain which can negatively impact pain management. Combining exercise therapy with pain education in a home-based program could improve patient outcomes and improve access for rural patients. An iPad may be useful in facilitating physical therapy access regardless of patient location and providing comprehensive care to manage LBP. The objective of this project is to develop and test an iPad application for home-based therapy of chronic low back pain.

Methodology

The patient education and exercise program is an iPad-based application. The initial prototype was developed by clinician study investigators by incorporating pain education and strategies for fear avoidance, stretching, strengthening and aerobic exercises, and relaxation techniques into a one hour session. The application reflects the frequency and duration of traditional physical therapy sessions, by providing three sessions a week for six weeks. After the first two weeks participants will have a virtual meeting with a study investigator to ensure their proper understanding of the exercise program and accessibility to the application content. Up to twenty adult participants with chronic LBP, will be recruited for the study. Both qualitative and quantitative measures will be collected. Participants will complete questionnaires assessing their depression, fear avoidance, disability, and pain at baseline and every two weeks during the study. Additionally participants will complete a telemedicine satisfaction questionnaire and the validated Computer System Usability Questionnaire after completing the program. Both usability results and participant reported changes in pain and fear will be evaluated to guide further application development. Participant comments during the virtual meeting will also be qualitatively analyzed for emergent themes to further guide development. This study was approved by the Institutional Review Board.

Results

Data collection is currently in process.

Conclusion

Testing is ongoing to design and optimize an iPad application to facilitate exercise and education for chronic LBP patients. Additional conclusions will be made once preliminary data has been collected and analyzed.

SCILHS Data Mart Creation Plugin

Michael E. Mendis, Janice Donahoe, Lori C. Phillips MS, Vijay A. Raghavan MS, Alexander Turchin, MD MS, Jeff Klann PhD, Shawn N. Murphy MD PhD

Partners Healthcare Inc., Massachusetts General Hospital, Harvard Medical School, Boston

Abstract

The Scalable Collaborative Infrastructure for a Learning Health System (SCILHS, pronounced “skills”) is a network of 11 health centers across the United States that will cover over 8 million patients. SCILHS is a Clinical Data Research Network (CDRN) in the Patient-Centered Outcomes Research Institute’s PCORnet.

Introduction

SCILHS has developed an Informatics for Integrating Biology and the Bedside (i2b2) information model that represents the PCORnet Common Data Model (CDM). This information model consists of an i2b2 ontology/terminology and process for mapping local data elements to the CDM. The ontology mapping is done without changing the underlying imported data. This approach highlights i2b2’s ability to separate the CDM from both information model and the underlying data format.

The sites will be able to programmatically generate i2b2 data marts that are based on the PCORnet CDM format, which will help assist in the patient clinical research. The DSD (Disease Specific Data mart) creation script assists the sites with creating a new i2b2 data mart based on an existing i2b2 query patient set.

For instance if a PI wants to do research on weight management, the first step is to run a query in i2b2 to find their set of patients. Using the plugin the PI can create a new disease specific data mart with only the patients in their defined i2b2 patient set. All of the data associated to those patients will be copied into the new data mart along with the ontology. The plugin has the flexibility to create either an Oracle or SQL Server script that contains the appropriate SQL statements that are needed for a DB to create the new data mart. Once the data mart has been created the PI can use the CT viewer within the i2b2 Workbench to manually review each patient to determine if they are suitable for the study.

The CT viewer provides the PI a friendly, user interface for rapid line-by-line viewing of patient attributes, and the ability to drill deep into an individualized view that can appear very similar to what an electronic medical record could produce.

Conclusion

The SCILHS data mart plugin assists the PI in fine-tuning a patient cohort for their study, by creating a data mart that contains only those patients who meet the specified criteria. Once they have this set, they can use the Clinical Trial (CT) viewer to determine if the patient is suitable for the study.

This work was (partially) supported through a Patient-Centered Outcomes Research Institute (PCORI) Award CDRN-1306-04608 (282364.5077585.0007)
Standardization of Ask At Order Entry Questions: A Prudent Question is One-Half of Wisdom

Riki Merrick, MPH\(^1\), Cynthia Johns, MLS\(^2\), Pamela Banning, BSMT\(^3\)
\(^1\)Vernetzt, LLC, Sausalito, CA, \(^2\)LabCorp, Burlington, NC, \(^3\)3M Health Information Systems, Murray, UT

**Problem:** The United States federal mandates for achieving Meaningful Use (MU) cause numerous work groups in the industry to discuss how to best represent actual content with standardized terminology. During the development of the Laboratory Orders Interface (LOI) and the electronic Directory of Services (eDOS) implementation guides in the Standards and Interoperability Framework’s (S&I Framework) laboratory related initiatives, the need for guidance, expansion and harmonization of Ask at Order Entry (AOE) questions became evident. Examples of such questions include: collection duration and volume of 24 hour urine for chemistries, and pregnancy/gestation questions for maternal serum integrated screening assays.

**Objective:** The primary goal is to provide a suite of harmonized standards for electronic messaging of laboratory data for the US realm for inclusion in MU regulations. A secondary goal is the reduction of variations in how the same AOE question is asked, for example, History of Down Syndrome (LOINC 53826-4) versus Prior Pregnancy with Down Syndrome. Use cases considered for this project were ambulatory laboratory test ordering as well as Public Health reporting, such as pediatric lead level reporting. Engagement of subject matter experts who help with consolidating duplicate AOE questions into a standard format for representation as a single concept provides further harmonization and enhanced interoperability. In addition, this project will establish a review process prior to submission for standard codes when new AOE questions are needed.

**Methods:** During the course of LOI and eDOS implementation guide development, commonly used AOE questions were collected from several national laboratories, Public Health laboratories and Public Health agencies. AOE questions were consolidated and standard codes were assigned from the Logical Observation Identifiers Names and Codes (LOINC\(^{®}\)) database, maintained by the Regenstrief Institute, where appropriate codes existed. AOE questions where the required information could be communicated in other parts of the HL7 message were also identified. Several of the AOE questions were asking the same questions in different ways and this duplication creates confusion and hinders semantic interoperability. The entire AOE collection was shared with the Laboratory Messaging Community of Practice (LMCoP), a forum comprised of laboratory and standards experts from state and federal Public Health laboratories, national clinical laboratories, the National Library of Medicine and professional organizations, whose purpose is to resolve lab related issues from a laboratorian’s viewpoint. The LMCoP, acting as a conduit to lab related professional organizations, provided its recommendations for subsequent review by appropriate laboratory domain content experts from the American Society for Clinical Pathology (ASCP), the Association for Molecular Pathology (AMP), and the College of American Pathologists (CAP) for completeness and proper LOINC\(^{®}\) code assignment, as well as identification of a preferred single concept representation where overlap existed.

**Results:** The current iteration of AOE questions contains 131 questions, a 37% reduction from the 210 originally collected. Fifty eight (58) new terms have been submitted to the Regenstrief Institute; in addition twenty three (23) existing LOINC\(^{®}\) terms were revised, removing trial status or survey-specific method information as result of this review. Specific test-related AOE questions will be grouped into LOINC\(^{®}\) panels in the coming releases.

**Conclusion:** The curated list of AOE questions, properly mapped to LOINC\(^{®}\) terminology, has been published in the eDOS Implementation Guide and is available to laboratories when implementing electronic data exchange. This project also established the review process for future new AOE questions for proper representation and evaluation of possible duplication, prior to submission for LOINC\(^{®}\) assignment by the Regenstrief Institute.

Intelligent Home Risk Monitoring Solution Enable Post Acute Care Surveillance

Hoda Moghimi, PhD, MSc., BEng1, Nilmini Wickramasinghe, PhD, MBA, GradDip, MgtSt, BSc.1,2, Jonathan L. Schaffer, M.D., MBA.3
1Epworth HealthCare Melbourne, Victoria, Australia; 2Epworth HealthCare and Deakin University, Melbourne, Victoria, Australia; 3Cleveland Clinic, Ohio, USA

Introduction

The advancing age of baby boomers, coupled with increased life spans, has led to a significant increase in the number of senior citizens in many countries. These populations are projected to significantly impact current and future healthcare resources. Providing care for this population in the acute care setting is only one aspect of the total care package that needs to be addressed. For those having been in the acute care setting for either medical treatment or following procedural based therapies, the discharge to home often provides an opportunity to continue the post acute care monitoring to ensure that complications or readmissions do not occur. Monitoring care and providing guidance and medical management at home will offer patients, families, facilities and providers with the opportunity to ensure recovery and return to a healthy steady state. To explore this issue further, the following examines the possibilities for monitoring post-operative clinical functions in the context of Total Knee and/or Total Hip Arthroplasty (TKA/THA). Specifically, this research in progress serves to proffer a conceptual model that can then guide a randomised clinical trial to test the presented Intelligent Home Risk Monitoring (IHRM) Solution.

Proposed Intelligent Home Risk Based Monitoring Solution

Decision-making regarding the treatment and surgery for patients under TKA/THA is especially multi-faceted and complex, including for example the clinical condition of the patients, their age and size. The decision to athroplasty treatments with either drugs, or surgery, or a combination of both depends on a large number of factors1. The decision making process in TKA/THA can be divided into six broad phases, as awareness program, outpatients clinic, pre-operative evaluation, day of surgery, post operative inpatient and post operative rehabilitation2. In the current process, nearly all patients receive post operative physical therapy and rehabilitative services in the hospital and despite the cost effectiveness of TKA/THA, rehabilitation costs in hospitals associated with these surgeries also place significant burdens on healthcare systems. Hence, it is understood that post operative home risk monitoring can be proposed to all patients who are identified in low risks or some patients with moderate post operative risks, through adopting a home based monitoring technology, as demonstrated in Figure1. The solution major functionalities include providing cause, effect diagrams and influence diagrams, showing the casual influences or relationships among variables and outcomes. Risk probability and impact assessment and risk categorization are further main capabilities of the solution.

Therefore, benefits of using the IHRM solution at home by both senior citizens and professional care providers can be summarised, as primarily clinical for optimal quality of care and access since these patients can now enjoy a post operative home care in a comfortable environment, early detection of post operative risk factors and also enhancing their autonomy through self-monitoring post operative conditions but also as economic benefits through saving rehabilitation costs in hospitals, logistics costs due to regular clinical visits and even environmentally friendly.

Conclusion

This research in progress has far reaching implications especially in light of the challenges facing many healthcare systems of an ageing population coupled with escalating healthcare costs and increases in chronic diseases as well as workforce shortage issues.

Improving Evidence-Based Migraine Management in VA Primary Care Clinics by Utilizing Informatics Tools

Amir Mohammad, MD, MPH, FACPM, Hamada Hamid, DO, Cynthia Brandt, MD, MPH
VA Connecticut Healthcare System, Yale University School of Medicine

Abstract
Migraine headaches are a common cause of impairment and lost employment productivity; people with migraines miss on average four days of work a year and cost the U.S. an estimated $13 billion a year. Veterans are particularly vulnerable to developing migraines because of their relatively high rate of traumatic brain injury. Having an immediate access to the evidence-based guidelines as a tool will assist in educating our clinicians to effectively manage migraine.

Introduction
Veterans are vulnerable to developing migraine headache. A study found that migraine headaches are more prevalent in service members who were deployed to Iraq. Another study found that the prophylactic medications to treat migraines were greatly underutilized in primary care settings. This study also highlighted the importance of enhancing the knowledge of general practitioners regarding the diagnosis of migraine, and to increase awareness of the headache guideline.

Methods & Results
Our baseline survey noted that the primary care clinicians were not consistently utilizing the evidence-based guidelines as only 65% reported utilizing American Academy of Neurology (AAN) guidelines when managing patients with migraine headaches. This survey also indicated that 75% of clinicians were prescribing anti-migraine prophylaxis and almost all of them (91%) were referring these patients to neurology clinics. This quality improvement project identified several non-value added steps. Since this project is currently being conducted in one of the primary care clinics, final results will be presented later.

Conclusion
Providing patient-centered care to veterans with migraine headaches require removal of non-value added steps in clinics and implementation of electronic tools. Utilizing the orders module in Computerized Patient Records System (CPRS), we will develop a Migraine Reminder Template and hyperlinks to Clinical Guidelines for Migraine.

Having an immediate access to the evidence-based guidelines as a tool will greatly assist in educating our clinicians, trainees, and nursing staff; and will subsequently promote timely and effective migraine management in VA Primary Care Clinics.

Assessing and Simulating Scheduling Processes in Community Health Centers

Iman Mohammadi, MS¹, Ayten Turkcan, PhD², Tammy Toscos, PhD¹,³, Amy Miller, MA¹, Kislaya Kunjan, MS, MBA¹, Brad N. Doebbeling, MD, MSc¹
¹Department of BioHealth Informatics, Indiana University, Indianapolis, IN; ²Department of Mechanical and Industrial Engineering, Northeastern University, Boston, MA; ³Parkview Research Center, Fort Wayne, IN

Problem. Community Health Centers (CHCs) are safety-net clinics providing primary care for underserved populations. Improving access to care is critical for establishing health equity, increasing quality, and improving health outcomes. In our ongoing research to improve access in CHCs, we found patients are concerned about long waiting times to get an appointment, not getting appointments at convenient times, and not getting appointments with preferred providers. Clinics face appointment scheduling challenges including provider shortage, limited provider availability, multiple patient visit types, appointment no-shows and cancellations.

Purpose. Effective scheduling processes can reduce clinic no-show rates and patient waiting time while improving continuity of care and overall clinic performance. We sought to develop a computer simulation model to assess and simulate the scheduling processes in CHCs, and provide a decision making tool for clinic managers to analyze the impact of a modified open access scheduling system, where some provider capacity is allocated for same-day appointments.

Methods. In this poster, we will describe the methodology used to develop the simulation model using clinical and operational data collected from CHCs. The data requirements, methods used for data collection, data analyses needed to represent the clinical practice realistically, and methods used for validation of simulation results will be characterized. Data requirements for the simulation model include provider characteristics, patient characteristics, appointment types, visit frequencies, and scheduling methods. Structured questionnaires and interviews were used to gather data about type of services offered in each clinic, number of providers, nurses and staff, access modalities, process to make an appointment, scheduling method and horizon, and enrollment visit processes. Clinic managers, staff, quality assurance directors, schedulers, financial advisors, nurse managers, call center staff and front desk staff were the key respondents. Workflow observations are necessary to fully understand the scheduling process in each CHC. The clinic staff working at the front desk (check in/check out), call center, scheduling and enrollment stations were observed to map the scheduling processes. Data from questionnaires and observations will be used to create a representation of patient flow and develop the scheduling algorithm. EMR data will be used to build patient population characteristics, and visit frequencies. No-show probabilities and cancellation rates will be estimated using statistical methods such as logistic regression. The simulation model will be validated by comparing the simulation output results with the CHC performance measures. The performance measures may include waiting times for appointments, number of patients seen by their primary care providers, and provider utilizations.

Preliminary Results. We have observed the scheduling processes in seven community health centers across state of Indiana. Our observations show that the scheduling process changes according to different patient types (new vs. established). Acute, non-acute, follow up and insurance enrollment (e.g. Medicaid and Medicare) visits are typically the four main appointment types. An agent-based simulation model was developed in AnyLogic in our earlier study¹. Here, the scheduling algorithm is updated based on our observations (e.g. scheduling enrollment visits for both established and new patients; scheduling enrollment and provider appointments on the same day; scheduling of patients with complicated conditions with physicians as oppose to nurse practitioners; and providing access through walk-in hours). For validation of the simulation model, the performance measures important for the CHCs are included in the model.

Conclusion. This project is part of a 3-year study funded by PCORI to understand and improve access to healthcare in Indiana through collaboration with seven community health centers in the state. Questionnaires and interviews for understanding overall operations of the partner clinics, workflow observations and EMR data analysis can be used to build the simulation model to identify effective scheduling processes and test alternate strategies to improve timely access to care.

Abstract

The use of electronic health records (EHRs) for the development of phenotype algorithms offers much potential, but is hindered in part by the lack of portable, standardized phenotype definitions. One solution is the creation of novel informatics tools to facilitate algorithm development. Here we develop design guidelines from potential end users of phenotyping software using qualitative methods. Results are presented as themes to inform the design of future software systems.

Introduction

Phenotyping is the process of systematic collection and analysis of phenotypic data.1 The implementation of electronic health records (EHRs) on the national level has a potential to tremendously scale the phenotyping process for clinical research through the creation of algorithms and tools to extract meaningful information from EHRs.2 However, one challenge is the lack of validated tools to author and apply standardized research phenotype algorithms across different sites and EHR systems accurately and efficiently. Towards this goal, participatory design enables designers and developers to learn user needs and preferences early in the design process through a workshop of diverse stakeholders. The results are early design ideas that can lead to the development of more accurate user requirements for research phenotype algorithm creation.

Methods

Following the process of participatory design, we invited 15 potential end users at Northwestern University and Mayo Clinic to use a prototype tool called “Phenotype Builder” prior to the design session. All participants provided informed consent to participate. Each participant was given access to the tool, two use cases and asked to create two phenotype algorithms. The use of the tool was recorded using screen capture software. After they completed the cases to the best of their abilities, all participants participated in a focus group to discuss their needs regarding the design of a future phenotyping tool.

Results

Most participants had experience with existing tools such as the Measure Authoring Tool (for creating electronic Clinical Quality Measures) and i2b2. Some had very little experience with tools, but had interest and/or experience in algorithm development. The primary usability requirements that emerged from the group were to (1) Present the algorithm in both graphical and technical form. (2) Provide a feedback system for the outcome of the algorithm. (3) Allow for flexible definitions. Since the main stakeholders of this platform are researchers, the definitions should be able to be extremely flexible for exploratory research design. (4) Provide built-in definitions. Electronic clinical quality measures usually have precise definitions of patient cohorts, however, this is less likely to be true in research. It could be useful to integrate the precise definitions from the quality-based work so that the researchers can cite directly if they want. (5) Develop detailed documentation for the platform. (6) Include search functions so that codes in standard vocabularies (ICD, RxNORM, LOINC, etc.) are searchable, and provide guidance toward which concepts are actually used.

Discussion

Participants provided requirements for the design of phenotyping tools that were related to the algorithm building activities and general usability. Developing a more useable system for building phenotyping algorithms can contribute to more robust research and clinic practice.

Acknowledgement. This work has been supported in part by funding from the NIH (R01-GM105688).

Using Natural Language Processing to Facilitate Medical Record Abstraction in Epidemiological Studies

Carlton Moore MD MS1,3,4, Kyle Shaffer BA3, Anna Kucharska-Newton PhD MPH2, Stephanie Haas PhD,3,4 Gerardo Heiss MD PhD2

1University of North Carolina School of Medicine; University of North Carolina at Chapel Hill; 2School of Public Health; 3School of Information and Library Sciences; 4Carolina Health Informatics Program

Introduction. The Atherosclerosis Risk in Communities (ARIC) study1 conducts ongoing surveillance of hospitalized cardiovascular health events and death in 4 communities in the United States (NC, MI, MN and MD). Diagnostic criteria for heart failure (HF) has been manually abstracted from medical records since 2005,2 including the presence of symptoms consistent with HF decompensation (new onset or worsening shortness of breath, edema, paroxysmal nocturnal dyspnea, and orthopnea) during patients’ hospitalizations. The manual chart abstraction process has high repeatability under a stringent quality control protocol, but is time consuming and costly. The goal of this study is to develop and test natural language processing (NLP) tools to extract information on complex symptoms of HF from free-text electronic medical records.

Methods. We used c-TAKES (clinical Text Analysis and Knowledge Extraction Tool), an open-source NLP software package3, to identify the presence of symptoms of new onset or worsening shortness of breath, edema, paroxysmal nocturnal dyspnea, and orthopnea in de-identified free-text electronic medical records from the ARIC study. We then created a program, written in Python, that processes the c-TAKES output to negate relevant concepts not consistent with new onset or worsening symptoms. For example, the shortness of breath concept in the text “the patient has chronic shortness of breath” is negated because the symptom is not new onset or worsening. Using an initial corpus of 112 medical records (representing 112 unique hospitalizations) adjudicated by ARIC nurse chart abstractors as the “gold” standard, we evaluated the recall and precision of the NLP system. We also investigated instances of discordance between the “gold” standard assessment and NLP results in order to identify areas for NLP algorithm improvements.

Results. The recall and precision of NLP vs. ARIC abstraction in identifying HF symptoms in the free-text corpus of 112 medical records is shown in Table 1. Recall was 100% for shortness of breath, paroxysmal nocturnal dyspnea and orthopnea; and 98% for edema. A review of instances in which NLP identified HF symptoms that ARIC abstractors had not (i.e., false-positives) suggests that NLP may be more sensitive than ARIC nurse chart abstractors (Table 2). For example, in one instance the medical record stated the patient “Has had runs of V-tach (ventricular tachycardia) overnight with shortness of breath”. This was correctly identified by NLP as new onset or worsening shortness of breath, but not by ARIC nurse abstractors. The precisions (Table 1) shown in parentheses are corrected for instances in which symptoms identified by NLP were overlooked by abstractors.

</tbody>
</table>

Discussion. We developed an NLP application that has close to 100% recall for identifying HF symptoms in free-text electronic documents. The NLP algorithm is being refined to further improve its performance characteristics and to extract additional ARIC HF symptoms embedded in free-text medical records. Our preliminary results indicate that, in some instances, NLP may be more sensitive than manual abstractors; and our results suggest that use of validated NLP technology holds the potential for improving the cost-effectiveness of epidemiologic surveillance.

The Everyday Practice of Health for Mexican Women in New Brunswick: Barriers and Opportunities

Miraida Morales, Ph.D. student, Xiaomu Zhou, Ph.D.
School of Communication and Information, Rutgers University, New Brunswick, NJ

Introduction
Half of New Brunswick residents are Hispanic, and yet not enough is known about this community (U.S. Census, 2010). A recent study showed significantly higher risk of problems of access to healthcare for Hispanic residents in New Brunswick (Stanley et al., 2008). Most of the existing research tends to lump Hispanic communities or Latinos into a homogenous group, resulting in a limited understanding of these communities. For instance, in the context of our study, many Mexican immigrants in New Brunswick, NJ, are of indigenous origins; grouping them with other Hispanic communities is not always judicious (Guarnaccia et al., 2012). Inspired by earlier studies, we seek to present a much more nuanced profile of the situation of this particular community in New Brunswick, in the context of their individual and community health practice. Due to women’s historical role in this community as primary caretakers for their families, they are the key for us to begin an exploration of the community’s health practices.

Objectives
The present study investigates (1) how Mexican immigrant women are able to continue to practice traditional or folk health practices when they settle in New Brunswick, and (2) how these folk health/medicine practices might be in conflict with health care programs, methods or treatment options they have access to in New Brunswick. Particular attention is paid to preventive health care methods, both as practiced by the community in their traditional or folk sense and as endorsed and promoted by the health care system in the United States, in order to identify when traditional methods clash or are modified vis-à-vis the dominant system as this group settles in the United States.

Method and Analysis
Several qualitative methods were used in this study including field observations, a structured survey questionnaire, and 2 focus groups. Theoretical sampling was conducted to identify study participants. In collaboration with community organizations, we conducted 2 focus groups with 14 Mexican immigrant women. Participants filled out a detailed demographic survey questionnaire. Focus group interviews were audio recorded to aid in transcription and analysis. Survey data was analyzed using descriptive statistics. Focus group qualitative data was transcribed and coded using a 2-step thematic analysis based on the Grounded Theory approach.

Preliminary Findings
Initial findings reveal several interesting themes related to the health practices of this community, including the role of food preparation and eating for maintaining health, how indigenous knowledge and cultural heritage influence members’ beliefs about health, and how members are able to maintain their health in their new environment (i.e. self-efficacy). Analysis uncovered the particular experience of rural and often indigenous immigrants in a large urban environment. Additionally, several institutional and systemic barriers emerged to community health practices, such as local agency policies, restrictions associated with the use of health insurance plans, local economic factors, interpersonal communication factors, and practices sanctioned by the local healthcare system.

Conclusion
The plurality of health practices in New Brunswick creates a complex environment that individuals must learn to effectively negotiate as they carry out the activities they associate with maintaining good health for themselves and their families. To better design and deliver health services to the Mexican immigrant community, we need to re-conceptualize health as a socio-cultural practice and to rethink the concept of “access” as these inform the context within which community health practices take place. Our research is still on-going, and we hope to further explore how culture and social factors determine health practices for the immigrant community, and how Health IT may help improve communication between the healthcare system and immigrant communities to support improved health outcomes through the development of socially and culturally relevant interventions. Health IT has the opportunity to address many of the communication and systemic barriers uncovered in the analysis.

Implementing Customizable Asthma Action Plans into an Electronic Medical Record

Stephen J Morgan, MD; Harley Z Ramelson, MD, MPH

1Partners HealthCare, Wellesley MA; 2Harvard Medical School, Boston, MA; 3Massachusetts General Hospital for Children, Boston MA; 4Brigham and Women’s Hospital, Boston MA

Abstract

An Asthma Action Plan is a written document that is provided to the patient in order to provide instructions on how to care for asthma symptoms at home and how to manage exacerbations. This poster describes the implementation of an electronic asthma action plan within a home-grown Electronic Medical Record and discusses some preliminary research data.

Introduction

The Longitudinal Medical Record (LMR) is an in-house developed ambulatory Electronic Medical Record used across Partners HealthCare. The LMR is a ONC-certified complete electronic health record. Included within the Patient Chart modules are actionable forms. The Asthma Action Plan (AAP) was first developed by the National Asthma Education and Prevention Program1-4 as a text based form that required manual entry of medications and specific instructions for the patient. This form is broken into three zones: green, yellow, and red, corresponding to the severity of respiratory symptoms. For example the green zone is a state of health with little or no symptoms while the red zone represents severe symptoms.

Features of the System

A text based AAP was initially developed in the LMR in 2007 and enhanced over time. The current AAP provides the ability to create the zones based on symptoms, predicted peak flow or personal best flow and to indicate the patient’s triggers. There is a direct link to the patients medication list, customizable favorite lists for each zone of the action plan, the ability to add of patient education forms and school based administration order forms, the ability to prescribe medications directly from the form, the ability to translate the form into Spanish and the ability to copy information from a previous AAP when creating a new AAP. Once completed, this form is made available in the Partners patient portal, Patient Gateway. An adult version of the form was recently released.

Results/Conclusions

Preliminary analysis of the usage data shows a steady increase in usage over the past 8 years. Overall, over 17,000 AAP forms have been created. As a result the future plans of this project are to assess the impact of adapting the form for adult patient use rather than primarily child health based. An additional area of research will be to investigate the impact on patient quality and improvement of asthma symptom control.

Extending the Project HealthDesign Experience via On-Line Public Data Repositories

Andrew J. Morland¹, Patricia Flatley Brennan¹, RN, PhD, FAAN
¹University of Wisconsin-Madison, Madison, WI

With the explosive growth in health tracking apps and the growing acceptance of their use in clinical care and self-management, app designers and developers are challenged to show validity and reliability of their tools. Indeed, the FDA Safety and Innovations Act calls for a risk-based regulatory approach to demonstrate app performance prior to their use in clinical practice. It is infeasible for every app developer to run a community-based clinical trial. Having access to data collected under similar circumstances would facilitate product testing and demonstrate app quality.

In Project HealthDesign five teams designed PHR apps that supported self-tracking of patient generated data. These teams generated thousands of data points representing time-stamped encounters used by patients to, for example, record mood or document meals. Grantee teams agreed in principle to deposit anonymized data generated by their apps into a public sharing repository. The Project HealthDesign National Program Office (NPO) selected ICPSR, the Interuniversity Consortium for Political and Social Science Research at the University of Michigan (www.icpsr.org).

ICPSR holds over 500,000 research data sets in the social sciences, including specialized data in education, aging and health among many other fields. ICPSR provides an efficient avenue for secondary data usage that allows researchers to bypass the onerous task of collecting primary data. The data sets that exist in the ICPSR repository are available to the public at no charge, and no registration or special credentials are required to view and use the data.

Creation, curation and use of data in research data repositories is more common in the bioinformatics research community than in the clinical informatics research community. Clinical informatics can contribute to and benefit from research data repositories. Primary investigations are expensive, and simply storing data after research questions are answered is wasteful. Research funding for individual investigators is becoming more challenging, necessitating investigators to seek new ways to answer research questions.

There have been notable efforts in the biomedical informatics communities to create large-scale data repositories. The Cancer Bioinformatics Grid (caBIG) espoused a bold vision to accelerate clinical trials and cancer research through a suite of data management, data storage and data sharing utilities. caBIG fell short of its intended goals and is defunct but the lessons about curation and data use policies remain valuable. NIH now maintains over 50 public repositories of research data. The Registry of Research Data Repositories (www.re3data.org) maintains an enumeration of over 1000 research data repositories and the APIs and related tools.

We prepared and deposited the Project HealthDesign data in ICPSR in Spring, 2015. The data pipeline is depicted in Figure 1. Each team collected the data according to their own research design and coding schemes. The NPO oversaw the curation of the data, which included over 12 months effort at standardizing variable labels, creating common code books and working with the individual teams to interpret data definitions. 13 data files including over 10,000 time stamped self-tracking events from over 100 unique patients were deposited.

The data deposited from Project HealthDesign has already been used in federally funded projects. Data from the BreathEasy project served as an initial data source for building a personalized prediction model.

Leveraging expensive field investigations through data sharing in public repositories can accelerate the development of high quality apps and contribute to patient centered care. (Support RWJF/NSF 1343969)

RECRUIT: Roadmap to Enhance Clinical Trial Recruitment Using Information Technology

Tasneem Motiwala, PhD; Chaitanya Shivade, BE; Satyajeet Raje, MS; Albert M. Lai, PhD; Philip R.O. Payne, PhD, FACMI
Biomedical Informatics, The Ohio State University, Columbus, OH

Introduction
Successful completion of randomized clinical trials, gold standards in medical research, is key to the progress of clinical and translational research. A major determinant of the success of a clinical trial is its ability to recruit the required number of participants. However, meeting the goals of trial recruitment is hindered by difficulties in identification of eligible patients that is, in part, due to complex nature of inclusion and exclusion criteria listed for trial protocols as well as the inability to efficiently match the criteria with patient’s clinical data. Despite efforts to alleviate obstacles associated with screening for eligible participants, statistics on clinical trial participation remain static. The purpose of this study is to automate the screening process through utilization of electronic tools coupled with a decision tree approach to sequentially narrow the search space in terms of all patients eligible for a specific clinical trial or vice versa.

Methods
Due to availability of clinical data for patients diagnosed with chronic lymphocytic leukemia (CLL), we will use CLL as a disease domain to test the feasibility of our proposed model. Records for all CLL trials conducted at The Ohio State University and listed in clinicaltrials.gov were downloaded as XML files. Eligibility criteria extracted from these records were segmented into individual sentences using the Stanford NLP tokenizer. Conceptual graphs were then used to identify similar concepts within the individual sentences (Fig. 1A) to determine their frequency of occurrence. Among these concepts, criteria that would be potentially useful in screening with the help of electronic medical records (EMRs) were identified and data corresponding to these criteria were classified as being present in discrete fields or in notes within the EMR.

Results and Discussion
In all, 84 relevant trials were identified from clinicaltrials.org. Some of the frequently occurring concepts for which data would be present in discrete fields within the EMR include pregnancy/nursing status, hemoglobin levels, HIV infection status, etc (Fig. 1B). Other frequently occurring concepts requiring extraction of information from notes include ECOG status (staging of CLL), presence of organomegaly, and fatigue levels (Fig. 1C). Some of the less frequent concepts were neutrophil counts, congestive heart failure, bilirubin levels, etc (Fig. 1D). Next steps would be to determine the populace of data within the discrete fields and the efficiency of extracting the necessary information from clinical notes. Based on these, a finalized set of useful criteria, including rare and frequently occurring ones, will be compiled and a CLL data mart will be created to hold data corresponding to these criteria. Algorithms will be developed to prioritize and order the eligibility criteria such that at every step the search space i.e. number of potentially eligible patients will be reduced. Data within the CLL data mart will be used to test these algorithms.

Figure 1: Example of a conceptual graph (A) and frequencies of frequent/discrete (B), frequent/notes (C) and infrequent (C) concepts.
An automated tool to replicate data between multiple versions of Profiles Research Networking Software’s (RNS)

Sukrit Mukherjee, MS, MSE, PhD¹, Sebastien Delta, BS¹
¹Charles R. Drew University of Medicine and Science, Los Angeles, CA, USA

Abstract

At Charles R. Drew University of Medicine and Science (CDU), we adopted different versions of Profiles RNS to use locally and to feed their data to other research consortiums. In order to synchronize information between different instances of Profile RNS which are architecturally different, we created an automated tool to implement replication of data involving complex cross-referencing, number of inner and outer joins and Node table lookup across different versions of Profiles RNS databases.

Introduction

At CDU, researchers are involved with clinical and translational research, especially focusing on health disparities. Center for Biomedical informatics provides investigators at CDU with state-of-the-art informatics solutions for their research projects. In 2011 We had adopted and heavily customized NIH-funded open source tool Profiles Research Networking Software (RNS) Beta Version and called it
Variation in EHR Implementations and the Impact on Safety of Test Result Follow-up

Daniel R. Murphy MD MBA\textsuperscript{1,2}, Michael W. Smith PhD\textsuperscript{1}, Dean F. Sittig PhD\textsuperscript{3}, Elise Russo MPH\textsuperscript{1}, Hardeep Singh MD MPH\textsuperscript{1,2}

\textsuperscript{1}Houston VA HSR&D Center for Innovations in Quality, Effectiveness and Safety, Houston, TX.
\textsuperscript{2}Baylor College of Medicine, Houston, TX.
\textsuperscript{3}University of Texas Health Science Center, Houston, TX.

Background
Breakdowns in the process of electronic health record (EHR)-based test result ordering and follow up are common and can negatively impact patient care. The causes of such breakdowns are multifactorial and include both organizational/social issues (e.g., workflow, training) and technical factors (e.g., EHR interface design). Increased understanding of these factors is needed in order to make test results follow-up and tracking fail-safe. As part of ongoing work to understand socio-technical factors involved in breakdowns of test results follow up, we sought to identify differences in EHR implementations that impact test result follow-up processes.

Methods
Employing an 8-dimension socio-technical framework for EHR implementation and use, we conducted literature reviews and gathered expert opinion from a multidisciplinary team to identify factors that could either positively or negatively impact fail-safe test result tracking and follow-up. We recruited 3 large healthcare facilities using commercial EHRs and one Veterans Affairs (VA) facility and performed EHR demonstrations at each site. For consistency and completeness, we developed and used an observation checklist and set of interview questions. Demonstrations were audio recorded, and detailed notes on each step were taken. The demonstrator (training staff) was asked to perform specific tasks related to the process of test ordering and result tracking and follow-up. For each step in the tasks, we ascertained whether certain factors were present and positively or negatively impacted fail-safe tracking and follow-up. Any between-site differences were noted, and the multidisciplinary team reviewed all differences to determine whether they provided better, worse, or the same level of safety as the features that existed at all other sites. A second round of demonstrations was performed to address any questions regarding survey items that emerged after the initial demonstrations.

Results
A total of 8 demonstrations were performed at each of 4 large healthcare facilities. Evaluations included two sites with Epic Hyperspace, one with GE Centricity, and one with the VA’s Computerized Patient Record System (CPRS). We found at least one ‘positive’ factor at each site not present at other sites, and only one site without any unique ‘negative’ factors. Positive factors* not present at all sites included: ability to track orders to completion (2 sites); ability to monitor results unopened by providers; use of structured data to code abnormal radiology reports; use of “Addended Alerts” to inform providers when original results were amended/modified; presence of useful contextual clinical information in the test result review screen (e.g., next visit date); on-site information technology (IT) staff support; and ability to send reminders to self at a future date (2 sites). Negative factors* not present at all sites included: presence of orderable items that do not lead to action (listed as “Do Not Order”); automatic removal of test results from the inbox after a pre-set time-period even if not reviewed by the provider; inability to determine if result is abnormal from the result review screen; laboratory result graphs that were difficult to interpret (2 sites); and inability to return a result to the inbox after it is removed without IT assistance (e.g., if a provider is interrupted during processing).

Conclusions
Real-world EHR implementations are accompanied by several factors that positively or negatively impact the safety of test results follow-up and tracking processes. Understanding of these factors can allow for the development of best practices for EHR design, implementation, and use that ensures safer tracking and follow-up of abnormal test results.

*Positive and Negative factors were identified at a single site, except were noted.
HDD Access – an Open Source Terminology Server with Publicly Available Healthcare Terminology Content

Senthil K. Nachimuthu, MD, PhD; Lee Min Lau, MD, PhD
3M Health Information Systems, Inc., Murray, Utah

Abstract

HDD Access is a publicly available terminology server published since 2012 by 3M with support from the Department of Defense (DoD) and the Department of Veterans Affairs (VA). HDD Access supports easy implementation, maintenance and use of both standard and local terminologies. It includes standard terminologies such as RxNorm, ICD-9-CM, ICD-10-CM, ICD-10-PCS and others. It also allows users to add their own terminology content. We will demonstrate the HDD Access terminology server, its terminology content, browsing, searching and authoring tools, web services API, and the lessons learned in creating a publicly available open source product. We will demonstrate how standard terminologies can be implemented easily, how users can create local extensions to support their own terminologies, and how applications can use terminologies through a web-services API based on HL7 Common Terminology Services.

Description of the System

HDD Access is a concept-based terminology server with content covering various domains within healthcare, which serves as an interlingua that spans the needs of several healthcare applications. HDD Access supports local extensions, permitting the users to integrate their local terminologies into their instance of HDD Access, which enables interoperability with standard terminologies. HDD Access enables semantic interoperability and terminology governance by following essential principles of terminology design, such as concept orientation, concept permanence, nonsemantic concept identifier, polyhierarchy, multiple granularities, multiple consistent views, graceful evolution, recognition of redundancy, and a framework for formal definitions, described in Cimino’s Desiderata (1998), and enables users to easily implement these best practices.

Innovative Features of the System

HDD Access is unique among publicly available free-of-cost terminology servers by including a concept-based terminology with about 500,000 concepts at present. HDD Access software is written in the Java programming language, supports multiple open source and proprietary relational databases (such as MySQL, PostgreSQL, Oracle, Microsoft SQL Server and H2) and works on both Windows and Linux operating systems.

HDD Access includes user-friendly web-based tools for browsing and authoring terminology content. It also includes an advanced search engine which helps to search concepts by finding synonyms, inflections and other variations of the input terms. HDD Access includes a RESTful web services API that supports both HL7 CTS v1.2 and 3M functions for querying and authoring the content.

HDD Access allows the users to load and integrate their own local terminologies as well as map them to standard terminologies while maintaining control over their content through a novel namespace design, which automatically manages inter-dependencies between various terminologies so that they can be authored, imported and exported while preserving content integrity.

Current Implementation Status

HDD Access was first released in August 2012 and monthly updates are published through the HDD Access website, located at www.hddaccess.com. The HDD Access terminology content and software are downloaded about 150 times per month on average. The HDD Access user community has more than 1,500 users as of February 2015. The entire HDD Access software package is distributed as open source under the Apache Software License version 2, which allows modifications and derivative works, including proprietary applications by end-users. The entire HDD Access terminology content is distributed free of cost under the HDD Access Content License, which permits commercial use as well as local extensions.
Large Scale Regional Medical Information Network Infrastructure

Naoki Nakamura, Masaharu Nakayama, Takuo Suganuma, Norio Shiratori, Teiji Tominaga
Tohoku University, Japan

Abstract
Since the Great East Japan Earthquake, we have been developing regional medical information network systems. The private cloud and network technologies were introduced to realize their pliability and scalability. In this paper, we describe network infrastructure essential for a large scale regional medical information network system.

Introduction
With the budget of the Japanese Ministry of Internal Affairs and Communications grant, we have been developing EHR (Electronic Health Records) systems named, Miyagi Medical and Welfare Information Network (MMWIN), where institutions, such as hospitals, clinics, pharmacy, and nursing homes upload medical treatment and health information records of patients and residents into the centralized storages. To realize a large scale EHR system over the whole prefecture, we built an advanced network infrastructure with pliability and scalability for this MMWIN system.

Large Scale Network Architecture for EHR
In MMWIN, various efforts are carried out to keep the system secure and stable at a lower cost. Figure 1 shows the overview of the network where firewalls are placed according to the security levels. Servers and switches, firewalls, load balancers, and routers are virtualized. Networks having different security levels are separated from each other by means of VRF (Virtual Routing Forwarding) technologies on both data center and branches. There are multiple virtualized routers and firewall on both data center and branches according to the security level so that each can be separated completely. As the tele-conference’s traffic passed through the internet, it can be completely separated from other traffic. In addition, VRF enables routers to run multiple routing instances, then it handles multiple network easily and securely as if there are multiple routers. DMVPN enables direct tunneling among branch’s IPsec routers. When a spoke router wants to transmit a packet to another spoke router, these two routers dynamically create an IPsec tunnel, and traffic is directly transferred to each other. With this technology, tele-conference traffic via data center can be diminished and as well as configuration of routers becomes simpler. System keeps high redundancy in both the access lines and network equipment becomes redundant, and that routing is controlled with dynamic routing, EIGRP. These technologies are essential for a large scale regional medical information network system in terms of pliability and scalability.

Evaluation
Unlike other EHR systems, MMWIN can not only provide multiple networks having different security levels, but also can cable of virtually closing secure networks. In addition, it is considered to be redundant configuration. To realize these networks according to different security levels, usually systems are very complicated. Although MMWIN can attain the simplification of system configuration effectively with advanced network technologies, such as DMVPN, VRF, and Dynamic Routing. Regarding scalability, we had verified the capacity, that this network infrastructure can run well with more than 700 routers in advance. Currently there are more than 450 branches of this network, problems such as congestion have not occurred and system can be kept stable.

Conclusion
We discussed about a network infrastructure for a large scale regional medical information network system. For more flexible operations, we are planning to develop management tools to provide services in a more effective manner.

Figure 1. Overview of MMWIN Network Constitution
A Prefectural Medical Information Network System Developed after the Great East Japan Earthquake

1Disaster Medical Informatics, International Research Institute of Disaster Science, Tohoku University, Sendai, Japan; 2 Medical Informatics Center, Tohoku University Hospital, Sendai, Japan; 3 Neurosurgery, Akita University Hospital, Akita, Japan; 4 Yamoto Clinic, Higashi-matsushima, Japan

Abstract
A medical network system, the Miyagi Medical and Welfare Information Network (MMWIN), has been in development since 2013. MMWIN allows the backup of medical information of hospitals, clinics, pharmacies, and care facilities. By the end of February 2015, more than 1.6 million registered patients and more than 42 million pieces of backed up data were recorded on it. Increasing patient registration and maintaining a balance between income and cost are critical to maintaining this project.

Introduction
The Great East Japan Earthquake of March 11, 2011, which devastated the northeastern coastal region of Japan and resulted in 15,890 deaths and 2,590 missing persons as of March 7, 2015, is one of the largest disasters on record. Many medical facilities were destroyed and medical information, whether on paper or on servers in hospitals and clinics, was lost. A shortage of medical information disrupted clinical activity. Japan recognized the importance of backing up patient data after the disaster.

MMWIN
In Miyagi prefecture, one of the areas most damaged by the Great East Japan Earthquake, a project to develop a network system among hospitals, clinics, pharmacies, and care facilities was launched in 2013. The system is the Miyagi Medical and Welfare Information Network (MMWIN). The government provided funding to the network throughout the prefecture for three years. The medical information of each facility has been backed up in case of a disaster. Moreover, the information has been shared among medical facilities, with the consent of registered patients. The backup system is based on the Standardized Structured Medical Information eXchange (SS-MIX), which enables data from medical record systems developed by different vendors to be stored in a similar format. As of February 24, 2015, the number of facilities with the MMWIN was 390. The number of registered patients was 1,697,850, or more than half the residents of Miyagi prefecture. Medical data—including patients’ basic information, disease names, blood tests, and prescription lists—included 42,578,989 items.

Problems
The MMWIN has encountered several problems. First, development has been dependent on the budget. Most income has come from the fees of medical facilities. However, the gap between income and the cost to maintain the system has remained large. Thus, sustaining the project is a great burden. Second, image data are not available, a shortcoming that distracts clinicians. Third, access to detailed clinical information is limited by the content that is required.

Conclusion
The MMWIN started in one area—Miyagi prefecture—after the Great East Japan Earthquake and has become prevalent throughout the prefecture. The number of registered patients and clinical data are increasing. However, several problems must be solved to maintain the system in the long term.

Evaluation of Perioperative Medication Errors and Adverse Drug Events

Karen C. Nanji, MD, MPH1,2,3, Sofia Shaikh1, Amit Patel, MD1, Diane L. Seger, RPh3,4, David W. Bates, MD, MSc2,3,4
1Massachusetts General Hospital, Boston, MA, Country, USA; 2Harvard Medical School, Boston, MA, USA; 3Partners Healthcare Systems Inc., Wellesley, MA, USA; 4Brigham and Women’s Hospital, Boston, MA, USA

Introduction: While perioperative medication administration presents particular patient safety challenges compared to other hospital settings, the literature on perioperative medication errors (MEs) is sparse and contains largely self-reported data.1,2 The validity and reliability of studies based on self-reporting of MEs in other patient care areas has been called into question.3,4 The purpose of this study is to assess the rates of perioperative MEs and adverse drug events (ADEs) in the perioperative setting, evaluate their root causes, and formulate targeted solutions to prevent them.

Methods: We iteratively revised a previously validated error detection framework to define what constitutes a ME and/or ADE. Anesthesia-trained study staff subsequently observed randomly selected surgical cases at a large tertiary academic institution to identify MEs and ADEs over a period of seven months beginning in November 2013. Chart abstraction was also performed to flag MEs and ADEs that may have been missed by observation. All events identified subsequently underwent independent review by two specially trained reviewers. Our primary outcomes were the incidence of MEs and ADEs in the perioperative setting.

Results: A total of 277 operations were observed with 3,671 unique medication administrations of which 193 (5.3%, 95% CI 4.5-6.0) involved a ME and/or ADE. Of the events identified 153 (79.3%) were MEs in which 32 had little potential for harm, 70 had potential to cause harm (near misses) and 51 resulted in patient harm (preventable ADE). Of the 91 (47.2%) identified ADEs, 40 (20.7%) did not involve a ME and 51 (26.4%) were due to MEs that resulted in patient harm. Of the 153 observed medication errors, 99 (64.7%) were serious in severity, 51 (33.3%) were significant and 3 (2.0%) were life threatening. The most common error types were labeling errors 37 (24.2%), wrong dosage errors 35 (22.9%) and omitted medications/failure to act 27 (17.6%). Medications most frequently associated with errors were propofol (30, 25.6%), phenylephrine (12, 10.3%) and fentanyl (11, 9.4%). Longer procedures, especially those greater than six hours, had higher total event rates (p = 0.000), ME rates (p = 0.000) and ADE rates (p=0.004) than shorter procedures. Also, procedures with 13 or more medication administrations had higher event rates (p=0.02) and ADE rates (p=0.002) than those with 12 or fewer medication administrations.

Discussion: We found that approximately one in twenty perioperative medication administrations included an ME and/or ADE. More than one third of these errors led to observed patient harm, and the remaining two thirds had the potential for patient harm. These rates are markedly higher than those reported by existing retrospective surveys in the literature.1 Based on the error types we found, we identified several strategies to minimize perioperative MEs and ADEs. These strategies include both technology-based interventions and process-based interventions. Examples of technology-based interventions include bar code-assisted syringe labeling systems, point-of-care bar code-assisted anesthesia documentation systems, specific drug decision support, and alerts. Process-based interventions include determining optimal timing for documentation, reducing opportunities for workarounds, connecting infusions to the most proximal IV port, rigorous vendor selection and strong training. Future analyses should target the implementation of process- and technology-based solutions that address the root causes of these errors in order to reduce their incidence.

Automated Approach to Extract Cardiovascular Phenotypes from Echocardiography Reports

Chinmoy Nath, PhD¹, Mazen S. Albaghdadi, MD², Siddhartha R. Jonnalagadda, PhD¹
¹Department of Preventive Medicine, ²Center for Cardiovascular Innovation, Northwestern University Feinberg School of Medicine, Chicago, IL, USA

Abstract
We developed an information extraction system, EchoInfer, using natural language processing (NLP) that extracts 66 cardiac structural and functional data elements from echocardiography report. Our automated approach to the characterization of cardiovascular phenotypes from reports containing structured, semi-structured, and unstructured data has important implications for the development of research studies and has the potential to impact patient care. EchoInfer is unique because of its comprehensive coverage of phenotypes present in echocardiography reports and an overall high accuracy of over 90%.

Introduction and Background: The goal of this study is to explore the feasibility and reliability of using natural language processing (NLP) for the extraction of multiple data elements from echocardiography reports. Echocardiography is one of the most commonly ordered diagnostic tests in cardiology. However, tools for the effective extraction of information from echocardiography reports that may inform clinical management and analysis of data for research purposes are lacking.

Participants and Methods: Echocardiography reports from 1547 patients (1053 men and 494 women, mean age 67.9±14.0 years) with a history of aortic bioprosthetic valve implantation were considered. Echocardiography reports contained four different sections: (i) report text, (ii) procedure components, (iii) measurement and calculations, and (iv) conclusion or summary. Sentences were separated from each other in echocardiogram reports and the sentences that do not contain any data element were discarded. We developed an array of regular expressions and rules based on initial set of data to extract 66 cardiac structural and functional data elements such as left ventricular ejection fraction (LVEF), valvular gradients and velocities from all sections of the report. A training set consisting of 5 batches of 20 randomly selected echocardiography reports were used to further modify the regular expression patterns. The output of the NLP analysis was then presented in a structured format that was amenable to analysis by the end-user for possible research and/or clinical purposes. The accuracy of EchoInfer was evaluated by an independent reviewer using another randomly obtained test set of fifty echocardiogram reports.

Results: The accuracy of EchoInfer was evaluated by an independent reviewer using another randomly obtained test set of fifty echocardiogram reports; i.e. 50*66 = 3300 phenotype values. EchoInfer was evaluated with widely accepted definitions of true positives, false positives and false negatives [1]; and it achieved a sensitivity (recall) of 94.03%, a positive predictive value (precision) of 95.64% and an F1-score of 94.83%.

Discussion and Conclusion: Previous attempts to characterize cardiovascular phenotypes using NLP from echocardiography reports have been limited by characterization of only a few cardiac data elements, such as LVEF [2]. We showed that NLP provides a powerful and reliable tool for the large-scale, comprehensive extraction of information from unstructured clinical notes such as echocardiography reports. The use of EchoInfer may have implications for the clinical management and research analysis of patients undergoing echocardiographic evaluation.

Development of a Methodological Protocol for Observing Pharmacist Information Needs While Using the EHR

Scott D. Nelson, PharmD, MS; Joanne LaFleur, PharmD, MPH; Guilherme Del Fiol, MD, PhD; R. Scott Evans, MS, PhD, FACMI; Charlene R. Weir, RN, PhD, FACMI

Introduction
The adoption of electronic health records (EHRs) has impacted how physicians, nurses, and pharmacists provide care for patients. Although many studies have examined EHR use by physicians and nurses, no studies have examined pharmacists' information needs or information seeking behavior in the context of EHR use. The Veterans Health Administration (VHA) is an ideal setting for studying pharmacists' information needs, as there is a long-established EHR as well as advanced clinical practice for pharmacists. However, standard methods of assessing information needs impose substantial challenges in this setting, including significant recall bias in interviews and surveys; the need for multi-media capture due to the rapid, dense, and variable nature of data in real clinical settings; restrictions on installing software (such as screen capture) in many institutions; and typical unavailability of access to log data along with the inability of log data to capture the use of external information sources (such as paper or whiteboards). Additionally, think-aloud techniques conducted in real life settings are very limited as experts have difficulty verbalizing their goals and tasks; and most people stop talking when they are thinking or processing complex information. Historically, eye-tracking tools have had variable success in the real clinical work settings due to their obtrusiveness and the granularity of data. To address these challenges, we developed and piloted a flexible method that could be used in other clinical settings, could capture gaze, and could minimize interruptions. The purpose of this poster is to describe the information integration benefits and challenges to this approach.

Methods
We observed seven clinical pharmacists in the inpatient setting while they reviewed patients in preparation for medical team rounds. The pharmacists were asked to prepare for rounds as they normally would in their work environment, evaluating real patients, and interacting with the medical team. To record the observation sessions and pharmacists' interactions, we used an eye-tracking camera from Pupil-Labs. During the observation, pharmacists were asked clarifying questions to better understand goals, mental models, responsibilities, perceived usefulness of different sources of information, and tasks. We would wait to ask the questions until subjects completed a task as to not disrupt the cognitive process of complex tasks. A researcher would also document field notes during the session and ask deepening questions about information needs and goals after the session. We used an iPad to record audio from the session that was merged with the video using Adobe Premiere prior to analysis.

Results
Overall, the study method was well received. Pharmacists were extremely supportive and excited to participate and use the eye-tracking device. There were no complaints of disruption, interference, or discomfort due to the device or study procedure, although it seemed somewhat distracting to other clinicians. Some of the benefits include the low cost of equipment; augmentation of observation and interviews with video-audio recording and probing questions; and immersion of the researcher in the pharmacists' environment with little disruption to the normal tasks. Some of the challenges included the lack of native audio recording with the Pupil-labs camera, video codec difficulties, and problems correctly correlating the pupil recordings with the actual location of the pharmacist's gaze. The video codec used by Pupil-Labs software (Matroska) is not natively supported on MacOS, so the video file had to be converted before importing into Adobe Premiere. While the pupil tracker did not provide the precise location of the pharmacist's gaze, it did provide a general area of gaze that helped in review of the verbal and observational data.

Conclusion
Using an eye-tracking camera along with contextual inquiry helped embed the researcher in the pharmacists' environment and overcome many challenges of studying VHA pharmacists' information needs in the EHR.

Early Detection of Heart Failure using Data Driven Modeling Approaches on Electronic Health Records: How far can one go without Domain Knowledge?

Kenney Ng, PhD1, Jianying Hu, PhD1, Yajuan Wang, PhD1, Walter F. Stewart, PhD2, Steven R. Steinhubl, MD3, Christopher deFilippi, MD4

1IBM Research, T.J. Watson Research Center, Yorktown Heights, NY; 2Sutter Health Research, Walnut Creek, CA; 3Geisinger Health System, Danville, PA and Scripps Health, San Diego, CA; 4Univ. of Maryland School of Medicine, Baltimore, MD

Abstract
This retrospective study on a 15K patient cohort investigated the feasibility of developing effective heart failure onset risk prediction models by applying data driven modeling approaches to electronic health record data. A predictive model built without using any domain knowledge about the data achieved an AUC of 0.802 (95% CI: 0.790-0.814).

Introduction
Heart failure (HF) is a major public health issue with increasing prevalence worldwide. Early recognition of HF pathophysiology prior to a clinical diagnosis would provide the means to implement lifestyle modification and pharmacotherapy interventions that may slow disease progression and improve patient outcomes. Developing knowledge driven models for disease onset risk prediction can take a significant amount of time and effort with data curation, data understanding, information extraction and modeling. It also requires domain specific expertise in all phases of the process. With the increasing amount of electronic health record (EHR) data available and advances in machine learning and data mining techniques, we examined how the use of generic data driven modeling techniques could be used to develop predictive models for incident onset of HF from EHR data without domain knowledge. The expectation is that such a data driven model can be used initially and later supported by domain specific knowledge to increase performance, improve interpretability and refine the clinical applicability of the model.

Methods
The study subjects consisted of 15,209 patients: 1,684 incident HF cases and 13,525 gender, age and physician matched controls. The longitudinal EHR contained demographic, vital, diagnosis, lab and medication data totaling over 32K unique variables. The creation of the case and control patient cohorts required domain knowledge, but the subsequent modeling did not use any domain specific knowledge about the patient data, i.e., the type and meaning of each variable was unknown. A feature vector representation for each patient was constructed based on the EHR data by specifying an observation window (two year duration, one year before the diagnosis date) and then aggregating all instances of the same variable within the window into a single value. Basic aggregation methods (Boolean, count, sum and mean) were used. Feature selection using the information gain measure was used to identify the top N features and predictive models (random forest classifiers with 100 trees) were trained using 10-fold cross validation. Performance was reported using area under the ROC curve (AUC) and 95% confidence interval (CI) metrics.

Results
Figure 1 shows prediction performance (in AUC) as a function of the number of selected features for five different feature construction aggregation methods: sum, count, Boolean, mean, and a type specific approach where mean was used for continuous numeric variables (labs and vitals) and Boolean was used for categorical variables (demographics, diagnoses and medications). For all aggregation methods, performance improved as more features were added (up to 500 variables) and then leveled off. The type specific aggregation method (●) performed better than the other methods and had an AUC of 0.802, 95% CI: 0.790-0.814 with 500 feature variables.

Discussion and Conclusion
Given a pre-defined set of case and control cohorts, an effective HF onset risk prediction model was developed by applying generic data driven modeling approaches to EHR data without using any domain knowledge about the data. As next steps, we want to quantify how much value (in terms of prediction performance) is added by incorporating successively more domain knowledge into the modeling process with a goal of trying to identify where use of domain knowledge would be the most productive in developing disease risk prediction models.
Role of Social Media in shaping public health messages regarding Human Papillomavirus (HPV) vaccinations

Lien B. Nguyen, MPH\(^1\), Priya Nambisan, PhD\(^2\)
\(^1\)College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI; \(^2\)College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI

**Introduction**

Human Papillomavirus (HPV) is the main cause of cervical cancer. Cervical cancer affects an estimated 14,000 women each year and 4,000 deaths annually in the United States (Center for Disease Control and Prevention, 2015). HPV is a common virus that is passed through sexual contact between persons. Cervical cancer is a preventable disease, when found early, through proper detection of health screenings and also through HPV vaccinations. The Internet, especially social media, has become a major platform for individuals to quickly access and share important information about health concerns. Social media sites such as Facebook and Twitter are utilized by millions of people each day for this. According to the Pew Research Center, a survey reported 81% of U.S. adults use the Internet and 72% say they have looked online for health information during the past year (2013). Information about cervical cancer and HPV vaccinations can be found, shared, and posted by different organizations and peers among popular social networking platforms. However, current research studies that are focused specifically on social media and cervical cancer prevention are limited and we do not know how social media influences the shaping of overall message regarding HPV vaccinations. The consistency of different messages posted every day on social media sites, which are accessible by massive groups of users, may impact the individual’s decision to take important steps towards preventative measures, such as to obtain HPV vaccinations, in order to help fight against cervical cancer.

**Objective** – The study objective is to determine how social media play a role in shaping public health messages especially in the case of HPV vaccinations.

**Methods** – The methods for this study included data collection from social media platform, Twitter, where we examined individual posts and comments discussing topics related to HPV vaccinations. Semantria program was used to perform Sentiment Analysis on data collected for a total of 4751 posts and comments, which ranged from June 2014 to May 2015. We classified them into positive and negative messages on HPV vaccinations. We further analyzed types of information and different sentiments shared among users about obtaining vaccinations for prevention against cervical cancer.

**Results** – This is a currently on-going research. Findings are expected to show how negative messages compete with positive ones in critical public health messages such as for HPV vaccinations. Detailed findings will be presented at the conference.

**Conclusion / Implications** – The study findings will reveal how current social media is used as a tool for communicating key information about HPV vaccinations to the online audience. From this, we will have an understanding of what types of actual information is being shared. The research findings will have important implications for future public health workers, online communications, and use of informatics to address public health problems.

Finding Similar Drug Classes using RxClass

Thang Nguyen, M.S., Lee Peters, M.S. and Olivier Bodenreider, M.D., PhD
U.S. National Library of Medicine, National Institutes of Health, Bethesda, Maryland, USA

Contact information: RXNAVINFO@LIST.NIH.GOV

Motivation
Drug classes constitute important information about the drugs and are critical to important use cases, such as clinical decision support (e.g., for allergy checking). Finding similar drug classes helps to identify important characteristics of drugs in different classification systems. RxClass, a web-based browser for drug classes, supports navigation between RxNorm drugs and drug classes from several sources (ATC, MeSH, DailyMed and NDF-RT), and allows users to explore similar classes.

Finding Similar Classes by Drug Membership
The RxClass application and its companion RxClass API offer functionality which allows users to retrieve similar classes relative to the selected class. Similar classes are defined here as classes which share a large proportion of drug members. The simple procedure for comparing two classes includes the following steps:

- Select a drug class (e.g., CALCIUM CHANNEL BLOCKERS (C08) in ATC) and display its members.
- Select the “similar classes” link above the list of drug members. A popup menu is displayed with the most similar classes (e.g., Calcium Channel Interactions in DailyMed). The class information along with the equivalence score is displayed for each similar class (here: 0.74).
- Select the “Venn” link to visualize shared vs. specific clinically significant drugs (ignoring base/salt distinctions) for the two classes as a Venn diagram, as well as a table. See figure 1.

In addition to retrieving similar classes for a given class, the RxClass API also supports the identification of classes from an arbitrary list of drug members (e.g., a drug value set).

Similarity Scoring
RxClass and the RxClass API similarity functions use equivalence and inclusion scores defined in prior work to find and rank similar classes. The equivalence score is based on the Jaccard coefficient, which we evaluated in previous work. The inclusion score identifies situations where a high similarity value is indicative of one class being included in the other.

Conclusions
Providing similar drug classes has been a missing piece of information in RxNav. With RxClass, we now provide a link between similar drug classes from various sources using its RxNorm drug membership.

RxClass is available from the main RxNav website (http://rxnav.nlm.nih.gov), along with additional information about RxNav and our APIs to various drug information sources.

Acknowledgments: This work was supported by the Intramural Research Program of the NIH, National Library of Medicine.

Figure 1. Sample screenshot of RxClass Similar Class Information
Multi-Agent (Team) Microworld Environments for Healthcare

Vickie Nguyen, MA, MS and Amy Franklin, PhD
School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX

Introduction

Much of healthcare relies on distributed clinical providers working together as a team to complete coordinated patient care tasks in complex clinical environments. However, these environments are not solely human based, but are socio-technical environments requiring interactions of humans with humans and human teams with technology systems. To create effective technology systems for clinicians to provide safe and high quality patient care, we believe it is vital to also design these systems according to team needs. Yet, how can we best evaluate how well these team-designed health information technology (HIT) systems actually fit team needs?

Creating a simulation of a multi-agent microworld may be the answer to effectively evaluating team HIT systems. To our knowledge, current healthcare team simulations mostly focus on examining training, levels of expertise, or individual technology system evaluations. This project is still in progress, but in this work, we briefly describe the creation of a multi-agent microworld of a complex clinical environment, the Emergency Department (ED), for the evaluation of team HITs and the microworld’s initial uses.

Methods

Microworlds are scaled-down simulations of the team task environment, are conducive for evaluating multiple participants simultaneously, have been utilized in other complex environment domains like aviation, and are created using cognitive engineering methods.

We based our ED microworld on a model derived from 226 hours of ethnographic non-participant observations and surveys of 485 Gulf Coast Trauma 1 Teaching Hospital ED clinicians. We focused on Attendings, Residents, Mid-Levels, and Nurses as they worked together to care for all patient types upon the patients’ entrance into the ED to their discharge or transfer from the ED.

From our findings, we created an ED environment where a team of clinicians must participate in multiple concurrent interactions with one another and a team HIT system to complete multiple coordinated patient care tasks. Figure 1 shows an example screenshot of our computerized ED microworld and its human to human and human to technology interactions.

We are currently in the process of evaluating how well a mobile application, designed to help facilitate ED clinical team communications, actually helps ED clinicians better manage interruptions in the ED. The ED microworld helps us simulate the necessary testing interactions.

Conclusion

Although still a work-in-progress, the multi-agent ED microworld seems promising in replicating real world interactivity and multitasking. Multi-agent microworlds can provide a helpful means for evaluating team HIT systems, and in turn, help create more effective technology systems for complex clinical environments.

Leveraging an Open Source Data Warehousing and Analytics Tool to Promote Longitudinal Research, Improve Knowledge Transfer and Avoid Redundancy Across Research Studies

Thomas Nutman, M.D.1; Alex Rosenthal, M.S.,M.B.A.1; Joe Croghan, M.S.1; Cathy Steel, Ph.D.1; Karla Feghali2; David Hardison, Ph.D.2

1NIH NIAID, Bethesda, MD; 2ConvergeHEALTH by Deloitte, Newton, MA

Abstract - A customized open-source platform designed to streamline research efforts for the NIAID / Laboratory of Parasitic Diseases (LPD) integrates data from multiple disparate data sources collected since 1974. Standardized data are organized around research subjects enabling scientists to perform retrospective analyses and plan prospective research studies. A customized individual patient profile provides a holistic and longitudinal view of research participants. Overall researchers experienced increased efficiency, accuracy, and cost-effectiveness of patient data management and analysis.

Introduction - The National Institute of Allergy and Infectious Diseases (NIAID) conducts and supports basic and applied research to better understand, treat, and ultimately prevent infectious, immunologic, and allergic diseases. The Institute manages and retains data collected from clinical and population health studies. As data collection and storage technologies evolved over time, data sets of different formats and structures have been dispersed across multiple sources including handwritten laboratory notebooks, Excel spreadsheets, and the NIH Biomedical Translational Research Information System (BTRIS).

Problem - To preserve existing clinical and scientific data for record keeping and potential re-evaluation and reproducibility, NIAID sought a flexible and extensible solution to store, maintain and extract diverse data sets from one centralized repository. Specifically, the Laboratory of Parasitic Diseases (LPD) was seeking a long-term solution to consolidate longitudinal data sets collected since the 1970s to avoid redundancy in re-running laboratory experiments and make any collected data available to current researchers and staff. Additionally, the integrity of data assets would be preserved for use in future research in the event that any scientist left NIAID, and thus, increase the ROI on the research funding that supported the initial data capture.

Solution - A customized version of the tranSMART version 1.2 Knowledge Management Platform, an open-source tool, was implemented that can integrate data from various clinical and field studies in a single standardized repository. This platform facilitates self-service analytics and is designed to help scientists develop and refine research hypotheses through a very user-friendly drag and drop interface.

The data in tranSMART is stored in a custom ontology or data hierarchy which was established in collaboration with researchers. This ontology allows users to quickly filter out their data of interest and perform various analyses by simply dragging and dropping patient cohorts into the interface provided by the tool. In addition, researchers are able to run rapid statistical analyses on data sets to support retrospective and prospective studies. An individual patient profile view was created which provides a temporal view of accumulated data, e.g., blood platelets assayed at multiple time points in a study of filarial infections. An incremental load feature allows researchers to upload new data to already existing patient records. This enables scientists to integrate their real-time findings with existing data. The tool also supports easy data selection and export enabling scientists to analyze their data using other analytical tools beyond the R-based selections in tranSMART. Both the data selection and analysis steps can be saved to a researcher’s personal workspace in tranSMART to facilitate reproducibility and collaboration.

Conclusion - Through data curation and loading into a central repository that is accessible through a self-service, easy to use interface, NIAID researchers can spend more time on scientific insight. Similarly, the Institute can achieve better returns on the funding applied to data capture, data management, and analysis while preserving its rich data assets for future use.
Development of Anatomical Radiology Ordersets

Kevin O’Bryan, MD, Charles H Andrus, MHA, Feliciano Yu, MD, MSPH, Phillip Asaro, MD, Stanley Paul Hmiel, MD, PhD

1St. Louis Children’s Hospital, St. Louis MO, and
2Washington University School of Medicine, St. Louis MO

Introduction

At St. Louis Children’s Hospital, orders for radiology exams are initiated from three disparate EHR systems (best-of-breed architecture). Each system has different exam nomenclature, causing inconsistencies and inaccurate orders. This led to delays in care due to clarification phone calls and inability to locate the appropriate orders. In 2013, through a hospital-wide multi-stakeholder process improvement effort (IS, clinicians, radiology staff), the disparate EHR dictionaries were harmonized with the existing Radiology protocols.

Intervention

After reviewing this problem with many trainees, who are the primary placers of orders in the institution, a solution was found in a standardized approach to radiology ordersets. To achieve this, a hospital-wide effort was launched to standardize the naming convention across multiple EHR systems as well as communicate with the clinicians ordering the exam. Synonyms were removed as they added confusion especially for trainees. Rather than an unending list of synonyms, the chief residents wanted the trainees to learn one standardized list of terms to use in the institution for radiology studies. Radiologist, orthopedists, radiology technologists, and pediatricians met on a regular basis to review terminology and agree upon naming standards. Through consistent naming of exams, trainees were forced to learn a specific set of terminology. To facilitate learning this set of terminology, ordersets were developed to assist order entry and facilitate education of these terms.

A radiology orderset was designed, initially for MRI orders and then CT and ultrasound orders. The order set was organized into a grid with rows and columns. Each row was a specific radiology study and there were 3 columns after each study for without contrast, with and without contrast, and with contrast studies. Studies were organized by clinical anatomy from head to toe. A sample is shown in figure 1.

Figure 1. Partial sample of MRI orderset organized anatomically and by contrast requirements.

Results

This intervention resulted in a 23.6% decrease in orders requiring corrections by radiology technologists. This rate of improvement was consistent for MRI, CT, and ultrasound orders. Currently approximately 30% of all CT, MRI and ultrasound orders are placed through these ordersets.

Conclusion

This approach to radiology orders was highly successful in both improving the accuracy of initial orders and teaching common terminology to the users based on usage rates. We believe this organizational strategy for radiology ordersets could be applied at other institutions as it was highly intuitive user interface that met the needs of the clinicians. We plan locally to expand our work to x-ray studies and other hospitals in our system.

Using National Database for Autism Research (NDAR) privacy-preserving record linkage protocol in the PEDSnet CDRN

Toan C. Ong, PhD¹, Michael G. Kahn, MD, PhD¹, Dan J. Hall²

¹Department of Pediatrics, School of Medicine, University of Colorado Denver, Colorado USA
²National Database for Autism Research, National Institute of Health, Bethesda, Maryland USA

Introduction: A national Pediatric Learning Health System (PEDSnet) is one of eleven Patient-Centered Outcomes Research Institute (PCORI) funded Clinical Data Research Networks (CDRNs), [1] In PEDSnet, a data-coordinating center (DCC) integrates clinical data from eight children’s hospitals nationwide into a centralized data warehouse and transforms the integrated data to the PCORNet common data model. PCORNet CDM v3 requires the inclusion of data sources other than the local electronic health records. So PEDSnet is integrating its current clinical dataset to external data sets by research subject. Because datasets are distributed among different institutions, a secure and efficient record linkage protocol is needed. A secure record linkage process must satisfy two security requirements: 1) No clear text personally identifiable information (PII) is sent to the DCC and 2) the hashing methods must be secure to protect against PII re-identification attacks.

The National Database for Autism Research (NDAR) project has developed a secure subject record linkage protocol based on centralized globally unique identifiers (GUIDs). [2] A GUID is a randomly generated unique string. The NDAR protocol comprises multiple steps, including locally encrypting PII using multiple one-way hash functions, transferring the hash codes to the NDAR server to assign common GUIDs to the same individual or to generate new GUIDs, and integrating distributed datasets at the data-coordinating center using the NDAR GUIDs. A brute force GUID generation attack is mitigated by stalling the user’s system response for 30 seconds following each 50 GUIDs returned and the GUID generation is continuously monitored. The current version of NDAR GUID tool generates SHA-512 hash with added salts, making collisions extremely rare, using a fixed set of linkage variables in multiple hash combinations allowing for common human factors entry errors to be identified. A future version of the NDAR linkage algorithm will be enhanced to incorporate more linkage variables.

Methods:

Discussion: The NDAR record linkage protocol can satisfy PEDSnet record linkage needs because this protocol 1) securely encrypts PII data locally using advanced hashing methods, 2) supports linking data from multiple partners and 3) gives the GUID back to the data partners. However, the current NDAR GUID generating tool has to be updated to separate the data encryption process from the data transferring process to transparently ensure that only hash codes are transferred to NDAR server. NDAR linkage algorithm must be modified to accept additional linkage variables, which will be used in case mandatory linkage variables are not available or incomplete.

Abstract: A National Pediatric Learning Health System (PEDSnet) integrates its clinical-based dataset with external data from various data partners. Because the datasets are distributed among different institutions, a privacy-preserving and efficient record linkage (PPRL) protocol is needed. A workflow to adopt a PPRL protocol developed by the National Database for Autism Research (NDAR) project is proposed to support these objectives.

Best Practices and Design Experiences in Health Information Technology (HIT) Systems: A Primer

Gloria A. Opoku-Boateng¹, MS, Anthony F. Norcio¹, PhD
Department of Information Systems, University of Maryland Baltimore County, Baltimore, MD, USA

Background: In healthcare where almost all Health Information Technology (HIT) systems are large and complex (based on tasks, users and environments), failure in design can result in both economical and human life losses.

Aims: There is the need to: re-evaluate the importance of planning in planning and system design, review recent successful and unsuccessful HIT system designs to find out how planning and design (alongside other practices) play a role in system success and positive user experience, and re-analyze design trends and come up with recommendations for better HIT system design.

Methods: This research is an exploratory study which is based on literature review of best practices, survey of subject matter experts and review of recent complex HIT systems for the above-stated research needs.

Results & Recommendations: This paper suggests six recommendations for incorporating best practices in system design of HIT software systems: 1. The need to fully understand the HIT domain; the healthcare, design and software development parts. 2. The need to understand the role and place of User-Centered Design and testing in HIT systems. 3. The need for a design team lead and/or expert in HIT (re-)design projects to help balance fuzzy logic versus structural IT logic. 4. The need to clearly distinguish system design vs user-experience for both development teams and users/clients. 5. The need for comprehensive analysis of any HIT system through planning. 6. The critical need for future work in the research and design process of HIT systems.

Conclusions: This paper is a call to arms to the HIT Systems community. A call to involve proper design processes and methodology in HIT systems. One cannot over-emphasize that fully planning and implementing the design of a HIT depends totally on a design team. Going through the system design cycle just like it is done for other complex IT systems does not cut it considering the risks and complexities involved in Healthcare IT systems. There is no doubt that a generally accepted convention for system design is to include both the feasibility and the requirements analysis phases but this should be an active phase where not only how viable a system is considered but how well do we know the current situation and proposed solution. Future research work is needed looking at bigger samples and also to test some of the theories and recommendations to see how they hold up.

Keywords: Health Information Technology (HIT), Software Development Life Cycle (SDLC) Feasibility Analysis, Requirements Analysis, User-Experience (UX), System Design.
Nurses’ Use of Electronic Health Records to Document Symptoms in Inpatient Settings: Preliminary Systematic Review Results

Mustafa Ozkaynak, PhD¹, Blaine Reeder, PhD¹, Lilian Hoffecker, PhD, MLS¹, Mary B. Makic, RN, PhD, CNS, FAAN¹, Karen Sousa, RN, PhD, FAAN¹
¹University of Colorado | Anschutz Medical Campus, Aurora, Colorado, USA

Introduction
Symptom management is one of the essential functions of nurses in inpatient settings. Electronic Health Records (EHRs) should support nurses in evaluating and monitoring symptoms. However, design and implementation of these technologies are critical factors related to the quality and quantity of this support. Moreover, suboptimal design and implementation of EHR technologies can hinder rather than facilitate the quality and timeliness of nurses’ documentation. Therefore, the purpose of this systematic review is to characterize the use of EHRs for documentation of symptom assessment and management in inpatient settings, and determine whether EHRs are more commonly used for specific symptoms. Understanding nurses’ use of EHRs for symptom management and documentation can give designers and researchers an opportunity to identify obstacles and facilitators to, as well as develop strategies to address, perceived electronic charting challenges.

Methods
The third author (a health sciences librarian) searched the Ovid Medline database (1946-2013) using MeSH and “free text” keywords that represented the concepts of electronic medical records, symptom documentation, and inpatient setting. For example, search terms for electronic medical records are represented by words, phrases, and acronyms like "chart," "medical records systems, computerized" and "EMR”. Space limitations precluded inclusion of all MeSH search terms. The last two authors provided nursing science and symptom expertise.

The search process yielded 274 studies. Studies that met inclusion criteria (a) were peer-reviewed; (b) explicitly mentioned EHRs; (c) their use by nurses; (e) to document patient symptom assessment and management; (e) in inpatient settings. Studies that were excluded described chart reviews but not the documentation process, physician-only documentation processes, nurses’ documentation processes but did not explicitly mention use of EHRs and/or were conducted in settings other than inpatient.

The first two authors conducted successive independent reviews and reconciliation of titles and abstracts, and full texts of downloaded articles. Reconciliation of title and abstract reviews resulted in 214 excluded studies, and full text reviews resulted in 50 excluded studies. Ten articles published from 2003-2012 were included. We conducted a preliminary analysis to identify symptoms, settings, challenges, and efforts to improve documentation.

Results
The most frequently documented symptoms were pain, breathlessness, fatigue, anxiety, nausea; and vomiting. Study settings described in included articles were post-surgery, oncology and palliative care settings. Reported challenges included: (a) the need for complex documentation of each symptom type; (b) lack of communication between staff; (c) fatigue while charting; and (d) inability of patients to fully communicate their symptoms (particularly pediatric population and those at end of life). Poor documentation results (e.g. missing essential details, lack of timeliness) were cited as a factor that led to patient safety and quality of care concerns. Interventions to systematize symptom management and documentation were cited as decreasing these concerns.

Conclusion
Full compliance with documentation of patient symptoms using EHRs in inpatient settings faces numerous barriers. EHR design should simplify documentation processes and decrease nurses’ data entry burden. Systematic approaches that account for individual, organization, task, and technology-related factors, and the interplay among them, could support nurses’ work and improve symptom management and documentation. The unique contribution of this review is that it narrows the gap in knowledge related to EHRs and nursing documentation. Full analysis of the completed systematic review will be presented at the AMIA Annual Symposium 2015.
Informatics Strategies to Address Cancer Worry of Urban Dominicans

Alsacia L. Pacsi, RN, DNS, CEN, CCRN, FNP¹ and Suzanne Bakken, RN, PhD, FAAN, FACMI¹,²
¹School of Nursing and Department of ²Biomedical Informatics, Columbia University, New York, NY

Abstract:
As part of the Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research (WICER) project, we conducted a survey that identified cancer as a worrisome health concern of urban Dominicans residing in Washington Heights/Inwood in New York City. Those who were married, younger, less depressed, and those who had received a cancer diagnosis previously were more likely to be worried about cancer. Survey data serve as a foundation to develop targeted informatics strategies to address cancer worry.

Introduction:
There is a paucity of studies centering on the correlates of cancer worry among Latinos from the Dominican Republic and the potential informatics strategies to address such worries. As part of the Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research (WICER) project, we conducted a survey that identified cancer as a worrisome health concern of urban Dominicans residing in Washington Heights/Inwood in New York City. The aim of this study was to generate potential informatics strategies based upon the correlates of cancer worry.

Methods:
The WICER sample comprised 3,079 Dominican respondents. Data were analyzed using descriptive and correlational statistics, and logistic regression with the dependent variable of cancer worry. Independent variables for the regression were: age, gender, marital status, education, socioeconomic status, previous diagnosis of cancer, anxiety, depression, sleep disturbance, and chronic burden. Potential informatics strategies were generated through brainstorming.

Results:
Most respondents were female and 63.9% identified cancer as a worry. Four variables significantly increased cancer worry: married marital status (OR = 1.19 [95% CI: 1.01, 1.40]), younger age (OR = .992 [95% CI: 0.987, 0.997]), less depression (OR = .96 [95% CI: 0.945, 0.982]), and cancer diagnosis (OR =2.269 [95% CI: 1.310, 3.931]).

Conclusion:
Study findings suggest that a high level of cancer worry exists in the community and that it is important to target messages about cancer based upon marital status, age, and whether or not someone has had a previous cancer diagnosis. This has several implications for informatics strategies. In terms of cancer worry, it may be useful to offer informatics-based tools in Spanish that will assist with calculation of risks for various cancers and culturally-relevant information related to level of risk. Given the Latino cultural value of familialism, it is not surprising that those who were married worried more. This suggests that informatics strategies should target cancer prevention for families, not just individuals. Personalism is also an important Latino cultural value. Thus, web-based video testimonials regarding cancer prevention that are targeted by age may be considered to be more relevant. The fact that those who had a previous cancer diagnosis were more worried suggests the need for tools that support cancer survivorship. Given that Latinos in general are most likely to access the Internet through their mobile phone than a desktop, it is important that cancer-related informatics strategies are suitable for mobile technology. Moreover, the relevance of SMS as an informational approach is also important given the predominance of basic rather than smartphones. The goal being to decrease cancer worry and empower the community to play more proactive role in making informed decisions and in turn promote their well-being.

Introduction: Sequence Pattern Mining discovers frequent sequential patterns in large sequential databases. Sequence pattern mining methods are applicable in a large number of applications and domains such as, analysis of DNA sequences, patterns in patient path, etc. In these applications, survey of medical data from multiple parties is important which leads to more accurate sequential pattern analysis. When doing sequence pattern mining across multiple parties, under the regulations of HIPAA, patient’s privacy should not be revealed. Therefore we need to propose new privacy preserving schemes to perform sequence pattern mining across different parties. Our proposed scheme can be applicable in healthcare industries to identify the patterns in patient path, patient health, disease, medication etc. as it involves multiple parties and needs to be done in a privacy preserving manner.

Problem Statement: The goal is to find out the most frequent sequential patterns held by two or more parties without disclosing any sensitive data to each other. Given n parties, each party I has a database D_I. The SLPMiner algorithm [1] is used to find frequent sequential patterns at each site, e.g., P_1, P_2, ..., P_L. Some pattern P_l may appear at different sites. Denote P_l^A the appearance of P_l at site A, and P_l^B at site B. \sigma(P_l) is the number of times of P_l being selected as a frequent sequential pattern at different sites. If it is over a threshold, P_l is one of the most frequent sequential patterns across the participating sites. Privacy preserving sequential pattern mining reveals only the most frequent sequential patterns to other participating sites. Any other original data is kept secret from other sites.

Overview of the Methodology: The overview of our methodology is shown in Figure 1. The main steps are listed below.

1. Each site applies SLPMiner algorithm to find the local frequent sequential patterns.
2. Each site encrypts the result of Step 1 using public key.
3. All sites send the encrypted frequent patterns to a randomly selected site R.
4. Site R calculates Jaccard similarity coefficients [2] between any two encrypted patterns, and calculate \sigma(P_l) for each P_l as \sigma(P_l) = [(A,B)](P_l^A, P_l^B) = 1, where A, B \in \{1, n\}. 
5. If \sigma(P_l) \geq \tau, P_l is considered as most frequent sequential pattern. The plaintexts of E(P_l)s are eligible to be shared/published among all sites.

Evaluation Results: We evaluate our solution using different datasets generated by the IBM Quest research group [3]. We used two datasets with different numbers of sequences (2,000 rows of data to 10,000 rows of data). Each sequence of data consists of eight itemsets on average. Fig. 2 shows the efficiency performance of our solution for Data – Time to get frequent patterns between two sites.

Conclusion: We propose a new privacy preserving sequential pattern mining algorithm across multiple sites. It keeps each site’s data hidden from other sites except the mining results.

Organizing Drugs in RxNorm by Therapeutic Classes

Matvey B. Palchuk, MD, MS1,2, Michael Kamerick1
1TriNetX, Inc., Cambridge, MA; 2Harvard Medical School, Boston, MA

Abstract

The therapeutic classification of drugs is used ubiquitously. In the public domain, NDF-RT’s “Drug Products by VA Class” provides the ability to organize medications mapped to RxNorm. We used it to group RxNorm ingredients by therapeutic class. The result, while useful for analysis, is missing 13% of the valid RxNorm ingredients.

Introduction

The adoption of RxNorm for representing medications is gaining momentum. However, RxNorm does not address one of the key use cases for working with medications – classification. NDF-RT, a “sister” standard developed by the Veterans Administration (VA) is distributed alongside RxNorm and goes a long way toward addressing this need, but it falls short in certain areas.

Clinicians and researchers commonly think of medications in terms of therapeutic classes. We are very used to classes like “antibiotics” and “beta-blockers.” A prototypical therapeutic classification that is certainly familiar to every clinician is found in the Epocrates app for mobile devices (Epocrates, Inc., San Francisco, CA), where users see therapeutic classes in an intuitive hierarchy of several dozen top-level nodes (e.g., Antimicrobials, Cardiovascular) and limited depth (only three levels). Organizing medications in this fashion facilitates electronic prescribing, use of medication information for reporting and business intelligence, and research.

While many software applications with user-facing medication information find it necessary to represent drugs in hierarchical structures, there is a paucity of therapeutic classification schemes in the public domain. The “Drug Products by VA Class” from NDF-RT is the most prominent1, but it is uncertain how frequently NDF-RT maintainers update this classification and its mappings to RxNorm; this presents a challenge in relying on this classification system.

Methods

Our goal was to group RxNorm ingredients by therapeutic class using NDF-RT. We downloaded RxNorm (http://www.nlm.nih.gov/research/umls/rxnorm/docs/rxnormfiles.html; accessed July 2014) and extracted the information into a relational database. NDF-RT therapeutic classification was derived from “Pharmaceutical Preparations/Drug Products by VA Class” parent node (NUI N0000010574). We traversed child-parent relationships to build our therapeutic classes hierarchy and “crossed over” into RxNorm at the level of clinical drugs (concept types SCD, SBD, GPCK and BPCK). Finally, clinical drugs were transformed into their corresponding ingredients using a “return the related concepts of specified term types” API call (http://rxnav.nlm.nih.gov/RxNormAPIREST.html).

To evaluate completeness of coverage, we obtained a list of all valid ingredients from RxNorm using a “return the RxNorm concepts for the specified term types” API call. We made certain that an ingredient had a corresponding clinical drug and excluded the ones that did not. We then compared the resulting ingredient list with the terminal nodes of the therapeutic class hierarchy we constructed.

Results

There are a total of 10,429 valid ingredients in RxNorm. The resulting NDF-RT therapeutic classification does not include 1,354 (13%) of them. This may be a reflection of the VA’s patient population – older and predominantly male.

Conclusion

Therapeutic classification in NDF-RT is very useful for organizing medications mapped to RxNorm, but it is incomplete. 13% of valid RxNorm ingredients – a significant number of medications – are not accounted for in this classification. Given how important therapeutic classification is for medication information, we would like to see it better addressed by standards in the public domain.

Perceptions of Health Information Technology Risks by Hospital Physicians

Sari Palojoki, M.Sc¹, Lasse Lehtonen, MD·PhD² and Kaija Saranto, PhD, RN, FACMI, FAAN¹University of Eastern Finland, Kuopio, Finland¹; University of Helsinki and Helsinki University Hospital District, Finland²

Introduction

Organizations can reduce the number and severity of electronic health record (EHR)-related safety events by anticipating the risk factors and an analysis of EHR-related safety concerns is a prerequisite for recognizing safety threats¹–².

We conducted a study to find out physicians’ perceptions of health information technology (HIT) risks. We identified all physicians employed in 23 different hospital facilities in Finland. Of these 2837 physicians, 650 were ineligible to participate in the survey because of absence from work or because they were not using EHR. Of the eligible respondents, 438 completed the survey, which yielded a response rate of 20%.

Materials, methods and results

A questionnaire based on Sittig and Singh’s theory and study findings¹–³ was constructed using a mixed-methods approach in several phases. A panel of experts in technology assessment, scientific background, clinical use of EHR and administration evaluated the face and content validity. Chronbach’s alpha was used for measuring internal consistency. The questionnaire consisted of eight set of questions, each with about five related questions about the design, development, implementation and the use of HIT. Statements were formulated with a five-point risk scale (from low [=1] to extreme risk [=5]). All responders were educated to use a standard risk matrix as a part of the hospital’s patient safety program.

The basic statistical analysis was performed by weighted average using the number of occurrences of each value as the weight. The highest perceived risk was the unavailability of the EHR (mean risk score 3.13). The second highest risk was in the failure to identify, find or use the most recent patient data. System-to-system interface errors were perceived as a high risk area e.g. due to the lack of direct interfaces between organizations (2.85). The highest risk scores were given by physicians working at emergency departments, operating rooms and intensive care units. The lowest risk was considered to be on the incorrect patient identification (2.39).

Figure 1. Mean risk scores of perceived HIT risks

Conclusion

HIT pose risks to patient safety. In our study, the physicians estimated that the HIT error types caused either a moderate or a high risks to patient safety. The study brings new data about perceived EHR risks: unavailability of the patients’ medical records, errors caused by miscommunication between applications and failure to find or use the most recent data were the most critical EHR safety concerns.

Measuring HIE in States and Factors Associated with States’ Success in HIE

Shriram Parashuram, PhD, MPH1, Seung Kim, PhD, MPH1,
Tianne Wu, MPH1, Prashila Dullabh, MD1
1NORC at the University of Chicago, Bethesda, MD

Research Objective
The State Health Information Exchange (HIE) Cooperative Agreement Program, enacted under the American Recovery and Reinvestment Act, expands the secure movement of electronic health information. As part of a multi-year evaluation of the program, we developed a composite measure of HIE progress for states in 2011, 2012, 2013. We studied the association between the composite state HIE measure in each program year, with program variables and pre-program contextual variables, to identify the key factors driving HIE in states.

Study Design
Development of a Composite State HIE Measure: We identified three priority domains of HIE: lab results exchange between hospitals and physicians, clinical care summaries exchange between physicians, and e-prescribing. From the American Hospital Association, National Ambulatory Medical Care, and SureScripts annual surveys in the three years, we identified provider-level measures that aligned with the three priority domains, and aggregated them to the state level for fifty-one states. After employing imputations to account for sampling variation in the three survey years, we standardized state-level measures and aggregated them domain averages for each state. The domain averages were appropriately weighted based on prior trends in adoption, complexity of exchange, and program goals, and aggregated into a composite HIE measure for each state.

Measuring factors associated with State HIE: Based on previous evaluation activities, we identified seven state program factors (e.g. laws to promote HIE under program, state-led HIE, availability of directed exchange services etc.) and eight state pre-program contextual factors (e.g. state size, population density, managed care penetration, level of hospital competition, pre-HITECH adoption of EHRs by hospitals and office based providers, etc.), conceptually associated with state HIE in the program years. We ran two sets of multivariate ordered logit models to study state contextual and program associated with states being in the highest HIE quartile: (i) multivariate models with contextual and program factors; and (ii) separate multivariate models with program factors and each endogenous program factor.

Principal Findings
States varied in their composite HIE measure across the three program years with changes attributable to state contextual factors in the early program years and program factors in the latter years. Smaller states, states with lesser competition among hospitals, and higher pre-HITECH office based-EHR adoption were likely to be in the highest HIE quartile. States that used query-based HIE with opt in consent models were likely to be in the lower HIE quartiles.

Conclusions
The results suggest that program factors became more important over the course of program implementation in their association with state HIE performance.

Implications for Policy, Delivery or Practice
Our objectives were to develop a state-level measure of HIE that was methodically robust, easy to compute and understand, accounted for program priorities, and was actionable, in that it allowed states to identify domains needing improvement. The composite measure also enabled us to study important contextual and program factors where states may want to direct their energies.
**Efficacy of Clinical Alerts to Decrease the Incidence of Contrast Induced Nephropathy**

Mark A. Parkulo, MD, Julia E. Crook, Ph.D, Launia J. White, B.S., Colleen S. Thomas, M.S. and March Rucci, M.H.A. Mayo Clinic, USA

**Introduction:** Contrast Induced Nephropathy (CIN) is a common and potentially preventable iatrogenic complication. We implemented Clinical Decision Support rules at Mayo Clinic in Florida between 2008 and 2010 to assist providers in identifying high risk patients and suggest alternative imaging or prophylactic measures to reduce the risk of CIN.

**Methods:** We compared the 12 month time periods before and after implementation of alerts with respect to the primary outcomes: (1) the proportion of patients with a creatinine test in the 30 days prior to imaging, and (2) the proportion of high risk patients receiving contrast. We secondarily examined the rate of CIN in patients for whom we had appropriate data. Fisher’s exact tests were used to compare the two time periods; graphical summaries were also used.

**Results:** Identification of high risk patients as evidenced by measuring of creatinine within 30 days of contrast use increased significantly for outpatients, both overall from 70% to 82% (P<0.001) and when focusing only on those who received contrast (see figure). However, there was no evidence of a reduction in the use of contrast in high risk patients. There was also no evidence of a drop in incidence of CIN, though this analysis was limited by (i) the fact that CIN incidence could be assessed only in those patients with appropriate pre- and post- creatinine measures, and (ii) the overall low CIN incidence.

**Conclusions:** The alert designed to increase the rate of creatinine measurement within 30 days of a potential contrast study was highly effective and sustainable as noted in the figure above, but the alerts designed to reduce the rate of contrast use were ineffective. This highlights the difference between actionable or nearly automatic alerts, such as ordering creatinine, as compared to alerts designed to inform or direct practice. The former alerts tend to be much more effective than the latter.
Building a custom lexicon for a large number of related concepts using templates

Olga V. Patterson, PhD\textsuperscript{1,2}, Matthew Freiberg, MD\textsuperscript{3}, Scott L. DuVall, PhD\textsuperscript{1,2}

\textsuperscript{1}VA Salt Lake City Health Care System; \textsuperscript{2}University of Utah, Salt Lake City, UT; \textsuperscript{3}Vanderbilt University, Nashville, TN

Abstract

Term recognition is the task of detecting the boundaries of a natural language expression in text that represents an underlying concept. Accurate term recognition relies on the availability of a comprehensive knowledge base that includes a representation of all text variations for a concept that can be potentially found in text. A data-driven lexicon generation results in a lexicon that more accurately matches the target corpus than an expert-driven approach.

This poster presents a method of developing a lexicon for a relatively large number of related concepts using patterns for a concept-value extraction of measurements in echocardiogram reports.

Background

Echocardiogram procedures result in a relatively large number (up to eighty) of heart function measures. In cases where these measures are not recorded in structured format, extraction from text of the report is needed. Concept-value pair extraction is a natural language processing (NLP) task that involves identifying occurrences of specific concepts in text and detecting the specific values mentioned in the document. In the case of extracting heart function measures, each measure is treated as a concept. The initial design challenge in creating such an NLP system is to identify the boundaries of terms for each concept. Abbreviations, spelling variations, word order variations, and misspellings create a large set of terms for each concept. An experienced clinician can create a list of some of these terms based on his/her personal knowledge because they are common. However, misspellings or less common variations require the list of possible terms to be determined by analyzing string occurrences in the text.

Methods

In the scope of a larger project aimed to extract heart function measures from clinical documents, a subset of the cohort was manually reviewed. It was noted that a large proportion of echocardiography reports followed one of several templates. While each of the templates used different words to express the same concepts, most templates contained similar patterns of concept and numeric value co-occurrence. These patterns are expressed as a linear sequence, in which a concept is followed by a short string of connective text and then by a numeric value with or without unit of measure, having one pattern per line of text. The text that appeared between terms and values was noted to be limited to a small set of expressions and to mostly contain punctuation or simple phrases. Since the number of the detected templates was quite large, manual annotation of all concepts in all identified templates was not feasible. However, templates prevalent in echocardiogram reports provided an opportunity for a semi-automatic acquisition of terms. We created an NLP pipeline that was able to extract potential terms from text. The system contains modules for: a) identifying phrases using regular expressions for finding numeric values with units and ranges of numeric values with units referred to as values [“0.4 mg”, “approximately 35%”]; b) identifying connective phrases using regular expressions that mark text typically found between terms and values [“is”, “=”, “!”, “found to be”]; c) using specialized annotation patterns that combine connective and value phrases using manually constructed patterns [“: 0.4 mg”, “ found to be approximately 35%”]; d) processing notes to identify strings in the concept slots as term candidates.

Results

A set of 445,487 documents was processed, and the term extraction resulted in a list of over 830,000 expressions. Most of these expressions were not related to any heart function concepts. However, the top 1000 terms of the most frequently encountered expressions were in fact representations of one of target concepts. The list of most frequent expressions was evaluated and a custom lexicon was compiled to link them to the concepts they represent.

Conclusion

Semi-structured documents allow for implementation of innovative approaches to building lexicons. The manual annotation burden can be eased leveraging templated sections of clinical documents through semi-automatic methods of term extraction.

Surveying Problem List Perceptions and Use in the Electronic Health Record

Darlene Peterson, MD1,3, Timothy Burdick, MD, MS2, Joshua Cohen3, Indra Neil Sarkar, PhD, MLIS3,5, Julie Lin, MD3,4, Dennis Plante, MD3,4, Elizabeth Chen, PhD3,5

1Maine Medical Center, Portland, ME; 2Oregon Health & Sciences University, Portland, OR; 3University of Vermont College of Medicine and 4University of Vermont Medical Center, Burlington, VT; 5Brown University, Providence, RI

Introduction
With the increased adoption of Electronic Health Record (EHR) systems, there has been renewed interest in the problem list and improving its use in the EHR. Several reports have described challenges for implementation and maintenance of problem lists, including the need for standardized coding, content, and use1,2. The goal of this survey-based study was to gain a better understanding of problem list perceptions and use at the University of Vermont Medical Center (UVMMC) for informing system improvements, user training, and policies.

Methods
A survey was designed and implemented using REDCap (Research Electronic Data Capture). Recruitment emails were sent to medical students and providers (physicians, nurse practitioners, physician assistants, fellows, and residents) at UVMMC in February 2013 and data collection was completed in March 2013. For closed-ended questions, basic statistics and graphs were generated; for open-ended questions, analysis involved developing and applying coding schemes for characterizing the contents of the free-text responses and identifying common themes.

Results
A total of 191 responses (~10% response rate) were received of which 160 (84%) were complete. Respondents represented a range of specialties with family medicine and primary care internal medicine as the most frequent; inpatient and outpatient settings; and, primarily attending physicians and residents/fellows. When asked to indicate where a particular condition should be documented in the EHR (problem list [PL], past medical history [PMH], past surgical history [PSH], family history [FH], social history [SH], or other), a variety of responses were provided for the 21 specified conditions. For example, 73% selected PL, 12% PMH, 73% SH, and 1% other for “ongoing tobacco use.” Several themes emerged from coding free-text responses to questions regarding problem list definitions, perceived barriers, and suggested improvements (κ>0.8 was achieved by two reviewers for a subset of responses). Overall, responses for definitions included the words “active” or “current” as well as referred to the problem list’s utility in healthcare decision-making. Some responses advocated for listing PSH, FH, or SH that have been deemed “important.” Overarching themes for perceived barriers included use of PL versus PMH, inconsistent use by providers leading to inaccuracy, and lack of ownership by providers. Overarching themes for suggested improvements included identifying one provider as “keeper of the list” (e.g., PCP) and building “hard stops” in the EHR to ensure that the list is updated by providers (e.g., at admission).

Discussion
The results from this survey are consistent with those reported in prior studies3,4. By evaluating both where in the EHR respondents would document specified conditions as well as their open-ended responses for problem list definitions and perceived barriers, varying perceptions and uses were observed. These findings provide further insights and guidance for standardizing problem list use, training, and policies.

Meta-Analysis of Ontology Applications in Healthcare

Kanitha Phalakornkule, MIS, MS, PhDc; Suhila Sawesi, PhDc; Josette Jones, RN, PhD
Indiana University, Indianapolis, IN

Abstract
This poster presents a meta-analysis of ontology applications within the last 15 years to evaluate the patterns of implementation processes and outcomes. The results showed that many studies needed to adjust the design of Ontology models in order to reach their long time goals. Upper ontology was absent in most of the applications even when their purposes was reuse and sharing. The role of upper ontology is to provide semantic interoperability of ontologies across applications (4). In addition, the majority of ontology implementations remain at strict research level and their long-term implementation plans were missing.

Background
Ontology is used to represent the conceptual structure of a specific domain by structuring its knowledge in hierarchal format. There is no right or wrong in ontological designing; however, the effectiveness of application is affected by the ontological knowledge model (1). Nowadays, the roles of Ontology in Information Science have been changing from an individual application like knowledge discovery, artificial intelligences (AI) and decision support systems (DSS) to a set of applications involving standardization, integration, reusability and interoperability connecting various unrelated applications to one another (2). The future of Ontology in healthcare tends to grow with the need of standardization and interoperability. Nevertheless, the current stage of Ontology in healthcare still requires more collaboration and understanding among applications in the domain (1) (3).

Method and result
To our knowledge, this is the first meta-analysis on ontology applications in the healthcare domain. In this study, our purpose is to analyze how Ontology has evolved in healthcare research and to discover what the outcome in Ontology implementation is. The PubMed was searched for studies published between 2000 and 2014 and potentially relevant studies were evaluated for eligibility. A total of 293 articles were met the predetermined inclusion criteria. During the data-analysis process, the patterns of ontology evolution in healthcare and the relations between their key attributes were evaluated.

In this meta-analysis, the purpose of integration is the most common (157 studies, 55.58%), while the purpose of reusability and prediction were the least common (19 studies, 6.48%). However, there were only 27 studies (9.22%) based on upper ontology models. Moreover, there were only 20% of the studies with the integration purpose were based on the upper ontology models.

The expectation is that this meta-analysis will lead us to better understand and to help us discover Ontological projects’ strength and weakness by presenting the relation between their proposes and their methodologies of the applications.

A Simulation Framework for Longitudinal Electronic Health Records Data

Matthew Phelan, M.S.¹, Benjamin A. Goldstein, PhD¹
¹Duke Clinical Research Institute, Durham, North Carolina

Abstract

Electronic Health Records (EHRs) are an increasingly utilized clinical data source. They are characterized by having multiple measurements on patients over time. Such longitudinal data present many analytic opportunities as well as challenges. These include: sampling analytic cohorts, modeling repeated measurements, and handling of missing and sporadic data. Having the ability to simulate realistic EHR data would allow researchers to study how different analytic approaches perform.

In this poster we present a simulation framework for EHR data. We model our simulation on EHR data derived from a large community hospital containing both inpatient and outpatient clinics. To motivate our example we consider laboratory measurements and biomarkers that are collected over time. We regard a patient’s presence in the EHR to be a function of several informative processes, namely an inpatient process and an outpatient process. We vary the rate of data collection depending on process state, mimicking the type of data one would observe in an EHR. Within this general framework, we consider such complicating scenarios as: data on multiple, correlated biomarkers, the presence of competing events, a cumulative effect of biomarkers on the probability of a given event, dynamic illness-to-recovery processes, and the presence of informative missing data. The final model is highly customizable allowing for varying degrees of prevalence of events, severities of illnesses and interactions among biomarkers.

Below, we illustrate how our simulation compares to real data. Figure 1a contains real glucose measurements on diabetics approaching a cardiac event, with a comparative control group. Figure 1b contains data from our simulated model illustrating how we are able to realistically capture the observed patterns.

Use of an Adaptive Agent-Based Model in Evaluating Patient Preferences in Healthcare

Andrew B. Phillips, PhD, RN\textsuperscript{1}, Margarita Sordo, MSc, PhD\textsuperscript{2,3,4}
\textsuperscript{1} MGH Institute of Health Professions, School of Nursing, Boston, MA; \textsuperscript{2} Clinical Informatics, Partners eCare, Partners Healthcare, Boston, MA; \textsuperscript{3}Department of Medicine, Brigham and Women’s Hospital, \textsuperscript{4}Harvard Medical School, Boston, MA

Introduction

The ability to effectuate change in healthcare increasingly relies on the skill of patients to make informed and intelligent healthcare choices. Whether these choices relate to the selection of providers, healthy behaviors, or insurance coverage, patients increasingly are at the center of healthcare reform efforts. Shared savings programs under the affordable care act reward improved patient outcomes through better patient management; meaningful use policies increase the information available to patients to manage their own care; wearable devices and the growth of mobile applications create additional sources of health data for patients. The goal is an “empowered” patient that efficiently navigates the healthcare system, making appropriate value-based decisions to reduce costs and improve individual and population health. New methods to model patient behavior are required for the design of technologies and policies that will successfully empower patients and transform care.

Methods

Complex systems science provides an opportunity to apply new tools to simulate and model patient behavior. A complex system describes a collection of agents that interact with each other to increase their individual health or fitness within a system. Each agent must make decisions based on individual preferences, values, and available alternatives within their environment. Due to the many interacting agents, complex systems do not behave linearly, but produce effects that are emergent and adaptive to changing circumstances\textsuperscript{1}. In the context of healthcare, patients can be considered one of the many agents interacting to maximize their health or fitness within a complex system. Three methods have emerged to simulate complex systems: system dynamics, network analysis, and agent-based modeling\textsuperscript{2}. System dynamics simulates system behavior through the operationalization of individual processes within a system to look at overall system behavior. Network analysis focuses on the relationships among agents within a complex system. Agent-based modeling simulates the complex system from the bottom up through the examination of individual agent behaviors based on discrete preferences, environmental factors, and interactions with other agents. Using agent-based methods we will develop a pilot computer-based adaptive model that identifies and operationalizes key health agents, agent properties, and interactions. Our model will potentially demonstrate the emergent behavior of patients in healthcare through the interaction of individual patients and other system agents.

Results

We hypothesize that an adaptive agent model will reflect the collective behavior and preferences of individual patients and their interactions with other agents in the system. By applying an adaptive agent model to simulate these patient behaviors patterns will emerge that potentially will improve our understanding of patient preferences, value perception, and decision-making.

Discussion

Healthcare continues to be modeled on provider-directed, evidence-based interventions that assume the patient is familiar and agrees on what is best for them – a provider centric top down model of care. The new roles envisioned for patients require bottom-up methods of evaluation to properly predict patient behavior. The development of an adaptive agent-based model allows for the consideration of the contextual, social, and other environmental impacts of the system on patients.

Data-driven identification of factors for appropriate selection of lab tests

Gouri Prakash, MISM, BE,
Independent Scholar, Mumbai, India

Abstract
The topic discussed in this paper is the systemic identification of lab tests that measure the same analyte from a data set, and the analysis and identification of heuristics that would guide the appropriate selection of lab tests.

Introduction
Enhanced decision support capabilities built into Computerized Physician Order Entry systems (CPOEs) at the point of entry of lab orders can ensure that clinician orders the right test at the right time for the right patient. It is no longer enough to give the clinician a laundry list of available lab tests to select from, in order to place the request for the lab test electronically vis-a-vis CPOEs. Building decision support, as an operational capability, involves identifying strategies that enable appropriate selection of lab tests at the point of entry for lab orders and LOINC can be leveraged to identify factors that enable the selection of appropriate test at the point of entry.

Methods
At the point of selection of lab tests, if two lab tests that measure the same analyte, are presented to the clinician, what factors drive appropriate selection of lab tests is the subject of this poster. LOINC has defined 5 parts for each lab test namely, component, scale, specimen, property, time and an optional sixth part, namely method. Component is the analyte of interest, or that biological, chemical or biochemical substance under measurement by the lab test. Scale indicates whether the lab test yields a qualitative or a quantitative result. Specimen is the source that contains the analyte, for example blood, urine, so on and so forth. Property refers to the property of the analyte under measurement, whether it is mass or volume concentration. The Top 300+ Commonly Ordered Tests hereby referred to as LOINC300+, which accounts for roughly 95% of all orders placed in the US, was downloaded from LOINC's official website and served to be the population of lab tests from which “matched pairs” were identified. Matched pairs are sets of two lab tests that measure the same analyte, however, exhibit variation in values for 0 or more for the other 3 LOINC attributes that characterize the test, i.e. Property, Specimen and Scale. All lab tests in the population had the value of ‘Pt’ (point in time) for Time and hence not being an attribute of discernment, it was excluded from the analysis. 41 panels present in LOINC300+ were excluded and for the 291 standalone tests, a JAVA program called LabTestAnalyzer was developed to extract ‘matched pairs’. Hence, a data-driven, systemic approach was devised to identify 2 lab tests that measure the same analyte from a standardized dataset. With the analyte (or Component), as the pivot, given the set of 3 attributes, {Property, Specimen, Scale} there were 2³ or 8 possible categories. Each matched pair was assigned to one of these 8 categories. Of the 24 matched pairs identified, 2 were excluded as 1 matched pair contained two tests which were identical and erroneously present twice on LOINC300+ and 1 matched pair had “XXX” as the value for Specimen. After the identification of the 22 matched pairs, the purpose and properties of each lab test were researched manually from the following sources of information on lab tests – (1) information provided in the Comment and Method_Typ LOINC supported fields (2) preamble available under the semantic category to which the lab test is assigned, in the Top 2000 Common Lab Test Results dataset (3) research papers in PubMed, indexed and retrievable by analyte name - to determine the differentiating factors that serve as a decision point for influencing test selection at the point of entry for lab orders.

Results and Discussion
22 matched pairs were identified which accounted for 44 of the 291 lab tests and each matched pair was assigned to one of 8 categories, for example, 7 pairs (31.8%) were assigned to Category 1, {Property, Specimen, Scale}, i.e. the values of all 3 attributes for both lab tests within the matched pairs assigned to this category were the same. Factors identified to be determinants for influencing selection between tests present within a matched pair were (1) purpose of test (2) sensitivity and specificity of test (3) analytical variation (4) processed versus unprocessed specimen (5) patient gender (6) different metric systems used in different countries (7) medication monitoring protocol as per clinical practice guidelines (CPG) (8) first line tests versus second line tests as per CPG. This poster highlights an application of data standardization different from interoperability - that of extraction of factors from standardized terminology to be used in the synthesis of lab test selection strategies at point of entry of lab orders.
Usability Testing of a Complex CDS Tool in the ED; Lessons Learned

Anne Press¹, Lauren McCullagh¹, MPH, Sundas Khan¹, MD, Salvatore Pardo⁴, MD, Andy Schachter¹, Thomas McGinn¹, MD, MPH

¹Department of Medicine, Hofstra North Shore-LIJ School of Medicine, Manhasset, NY, USA
²Department of Emergency Medicine, Hofstra North Shore-LIJ School of Medicine, Manhasset, NY, USA

Objective: Conduct usability testing to formulate an approach to successful implementation of the Wells criteria into the Electronic Health Record (EHR) in the Emergency Department (ED) of a large tertiary hospital.

Background: As the EHR becomes the preferred documentation tool across medical practices, healthcare organizations are pushing for clinical decision support (CDS) tools to be embedded into the EHR, to help bring evidence based medicine to the forefront of patient-physician interactions. However, often CDS tools are integrated into the EHR without an initial phase of usability testing, resulting in poor adoption rates. Usability testing is important because it evaluates an EHR CDS tool by testing it on actual users. An example of failed attempts to integrate CDS tools into the EHR, due to poor usability testing, is prior attempts to support appropriate decision-making regarding ordering CT (Computed Tomography) scans for the assessment of Pulmonary embolism (PE). This abstract outlines the usability phase of a study, which will test the impact of integration of a CDS tool for PE diagnosis into the EHR of a large urban Emergency Department, where workflow is often chaotic and high stake decisions are frequently made. We hypothesize that by conducting usability testing prior to the integration of the CDS tool into the EHR will result in increased physician adoption rates.

Methods: We conducted usability testing of a CDS tool that will be embedded into the ED EHR. The CDS tool consisted of the Wells rule for PE in the form of a calculator and was triggered off either CT orders or patients’ chief complaint and pertinent medical history. The study was conducted at a large tertiary hospital in Queens, New York. In addition to testing overall functionality, our specific usability question was whether a CDS tool with an earlier trigger (triage note) would be preferred to a later trigger at order entry. Seven residents were recruited and participated in two phases of usability testing. The number of participants recruited for this study was based on feedback from previous usability testing where a saturation of feedback was identified at approximately four participants. The usability testing employed a “think aloud” method, which called for participants to verbalize all thoughts as they interacted with the EHR and CDS tool, and “near-live” clinical simulation, where care providers interacted with standardized patients enacting a clinical scenario. Both phases were audiotaped, video-taped and had screen-capture software activated for onscreen recordings.

Results: Phase I: Data from the “think-aloud” phase of the study showed an overall positive outlook of the Wells CDS tool, in assessing a patient for a PE diagnosis. The subjects described the tool as “well-organized” and “better than clinical judgment”. Changes were made to improve placement of the tool into the EHR to make it optimal for decision-making, auto-populating boxes to minimize click fatigue and automation of the diagnosis into the documentation. Phase II: After incorporating the changes noted in Phase 1 participants noted improvements in the tool. There was less toggling between screens and the participants were able to complete patient visits more efficiently. Furthermore, it was clear from resident feedback that a triage note trigger assisted with decision making more so than the order entry trigger location.

Conclusion: This study successfully combined “think-aloud” protocol analysis with “near-live” clinical simulations in the usability evaluation of a CDS tool that will be implemented into a large emergency room
environment. Both methods proved useful in the assessment of the CDS tool and allowed us to refine the usability and workflow of the tool. The most effective point for triggering of the PE CDS tool was determined to be at the point of the triage nurse. In this manner we were able to prove the effectiveness of initial usability testing and its role in the implementation of CDS tools into the ED. Given the complex workflow of the ED, near-live testing and simulation environments are the most effective for this purpose.
Comparison of Knee Replacement Bundled Payment Pricing Variances Between Medicare, Medicaid, and Commercial Payers

Taylor R. Pressler, MS\(^1\), Thomas R, Gurgiolo, MA\(^1\), Scott Orme, PhD\(^1\), Robert Kershner, MPT MBA\(^2\), Jonathan D. Mathieu, PhD\(^2\),
\(^1\)Aver Informatics, Columbus, OH; \(^2\)Center for Improving Value in Health Care, Denver, CO

Abstract

Payment reform will include bundled payments. CIVHC is an all payer claims database within Colorado and presents a unique opportunity to compare costs and utilization patterns within an episode of care between payer groups. Episode analytics will provide an insight into providing clinically precise care that is financially efficacious.

Introduction

Bundled payments are defined as the reimbursement of health care providers (such as hospitals and physicians) "on the basis of expected costs for clinically-defined episodes of care"\(^1\). In 2013, Medicare started a pilot bundled payment program. Since then, several states, including Arkansas and Ohio, are starting bundled payment pilot programs for Medicaid populations. The Center for Improving Value in Health Care (CIVHC) is an all payer claims database for Colorado and offers a unique opportunity to examine claim and quality variances in care between different payer populations within the state. CIVHC is one of eleven such state claims repositories in the US. The focus of this paper will look at the differences between different payer groups (Medicare, Medicaid, and Commercial) and cost variations within a Knee Replacement episode.

Methods

The Knee Replacement episode was constructed using the Prometheus 3.6 definition. This definition provides codes and definitions for establishing which claims are part of a valid Knee Replacement episode, including which claims are considered Typical or Potentially Avoidable Complication (PAC). Episode results were compiled using the Aver Informatics platform and the results stratified by payer. In the case of dual eligibility, payer was determined by primary eligibility. Results to be included in the final poster presentation will include total allowed episode costs, average PAC cost, PAC proportion of total episode spend, and the ratio of PAC/Typical episode costs. Differences between groups will be compared using a Student t-test adjusted for multiple comparisons.

Results

Table 1 shows the results of the Knee Replacement episode. The Commercial payer grouping has the highest average episode costs, but the smallest proportion of PAC claims. This may indicate that providers have higher utilization of services during the episode. Additional analysis will be presented at the time of presentation to break out the differences in utilization patterns between payer groups.

Table 1. Results of the Knee Replacement episode comparing episode outcomes between payer groups.

<table>
<thead>
<tr>
<th>Payer</th>
<th>Total Episode Costs</th>
<th>Average Episode Costs</th>
<th>Average PAC Costs</th>
<th>Percent PAC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medicare</td>
<td>$7,172,911</td>
<td>$13,901</td>
<td>$3,359</td>
<td>24%</td>
</tr>
<tr>
<td>Medicaid</td>
<td>$7,763,544</td>
<td>$19,856</td>
<td>$7,564</td>
<td>38%</td>
</tr>
<tr>
<td>Commercial</td>
<td>$50,170,919</td>
<td>$28,013</td>
<td>$5,584</td>
<td>20%</td>
</tr>
</tbody>
</table>

Conclusion

Commercial payers have the least restrictions when it comes to the payment of fee for service claims. By utilizing the complete data within the CIVHC all payer claims database, differences in costs and utilization patterns can be examined between different payer groups for a large population. This will provide a unique opportunity for finding opportunities for optimizing payment reform by using a large claims data repository.

Clustering Health Data to Discover EBP Interventions for Sepsis Prevention and Treatment for Health Disparities

Lisiane Pruinelli, MSN, RN1; Pranjul Yadav2; Andrew Hangsleben2; Kevin Schiroo2; Sanjoy Dey, PhD-C2; György J. Simon, PhD3; Maribet McCarty, PhD, RN4; Vipin Kumar, PhD2; Connie W. Delaney, PhD, RN, FAAN, FACMI1; Michael Steinbach, PhD2; Bonnie L. Westra, PhD, RN, FAAN, FACMI1,3

1School of Nursing, University of Minnesota; 2Department of Computer Science & Engineering, University of Minnesota; 3Institute for Health Informatics, University of Minnesota; 4Hennepin County Medical Center

Introduction
According to the Center for Disease Control and Prevention, sepsis or septicemia has doubled from 2000 through 2008, and hospitalizations have increased by 70% for this diagnosis. Patients with this condition are sicker, have longer hospital stays, and are more frequently discharged to other short-term hospital or long-term care institutions than patients with other conditions. Furthermore, there is a high rate of death or permanent organ damage, increasing health cost and burden. Despite the increasing number of new interventions and treatments, the challenge is early detection and prevention of sepsis and related complications. Use of evidence-based practice (EBP) guidelines, such as the Surviving Sepsis Campaign, could lead to earlier diagnosis, and consequently, earlier treatment of sepsis. However, these guidelines have not been widely incorporated in clinical practice. The overall goal of this study is to analyze patterns of EBP guidelines use and changes in health status over time, particularly for patients with health disparities.

Methods
After IRB approval, data from the EHR of a health system in the Midwest was transferred to a clinical data repository at the University of Minnesota established through a Clinical Translational Science Award. All episodes of care for patients hospitalized between 1/1/09 to 12/31/11 with a sepsis diagnosis were obtained and de-identified. Data included in the study were encounters, demographics, diagnosis, flowsheets, laboratories, medications, problems lists, and social determinants. Propensity score matching is used to compare a patient’s propensity in receiving guidelines interventions or not for different complications. Data mining techniques are used to create clusters of patient characteristics and to analyze the trajectories of these groups. Trajectories for EBP guidelines and groups conditions will be compared through survival curves.

Results/Discussion
The cohort contains 1,215 patients with ICD-9 codes for sepsis, SIRS, septic shock, laboratory associated sepsis, septic pulmonary embolism, and urosepsis. The risk for death for this sepsis cohort was 26.6%. However, when considering the risk for each of the ICD-9 codes, it was found that septic shock had the highest risk 46.9%, while septic pulmonary embolism had the smaller risk of death 11.3%. The majority of the patients are white (45.3%), followed by blacks (31.6%), and other ethnicities (23.1%). With respect the payer type, 13.44% were Medicaid, and 85.56% were no-Medicaid. Descriptive results comparing actual care to the EBP guidelines for the population as a whole and for those with health disparities, such as ethnicity and payer type, and other variables from the clustering analysis will be reported. Mining techniques applied to this cohort provide a better understanding of differences in predictive factors among septic populations that have different health outcomes. This study can contribute to better design and implementation of EBP guidelines to enable prevention, earlier detection and, better treatment of sepsis in specific disparate populations.

Blood Flow Model for Improved Decision Support

Charles Puelz, M.A.¹, Beatrice Riviere, Ph.D.¹, Craig G. Rusin, Ph.D.²
¹Rice University, Houston, TX; ²Texas Children’s Hospital, Houston, TX

Description

This work is focused on improving clinical decision support and critical care provided to children impacted by Hypoplastic Left Heart Syndrome (HLHS). This congenital heart defect renders the left side of the heart useless; in turn, affected children undergo a sequence of three surgeries altering their cardiovascular plumbing to an abnormal state that functions with a single right ventricle pump.¹

We hope to improve critical care by building a mathematical model of this physiology, coupling the model with physiological data from Texas Children’s Hospital in Houston, Texas, and then interrogating the model with clinically relevant questions. In this way, clinicians and caregivers providing care to these patients at the bedside will be armed with enhanced knowledge about this complex physiology.

The mathematical model will be constructed with a network of one–dimensional elastic vessels representing the arterial and venous circulations. Zero–dimensional models for the organ beds and heart will be incorporated as boundary conditions into the vessel network. We will simulate these equations with a method similar to the one detailed by Sherwin et al.² Lastly, the data we will use for model calibration and development will come from the Catheter Lab at Texas Children’s.

Data Integration Opportunities and Challenges for the ADVANCE Clinical Data Research Network

Jon Puro, MPA¹, Vance Bauer, MA¹, Jennifer E. DeVoe, MD¹,², DPhil, Rachel Gold, PhD², MPH, Erika Cottrell, PhD, MPP¹, Andrew Brickman, PhD³, Christine Nelson, PhD, RN¹, Kenneth H. Mayer, MD⁵, Abigail Sears, MHA, MBA¹, Scott Fields, MD¹,², Pedro Rivera

¹OCHIN, Inc., Portland, OR., ²Kaiser Permanente Health Research, Portland, OR Inc., ³Health Choice Network, Portland, OR., ⁴Oregon Health and Sciences University, Portland, OR, ⁵The Fenway Institute; Boston, MA.

**Objective:** The Accelerating Data Value Across a National Community Health Center Network (ADVANCE) Clinical Data Research Network (CDRN), funded by the Patient Centered Outcomes Research Institute, is “horizontally” integrating outpatient electronic health record (EHR) data for federally qualified health center (FQHC) patients, and “vertically” integrate hospital, health plan, and community data for these patients. The CDRN serves as a “community laboratory” for engaging vulnerable patients in Patient Centered Outcomes Research (PCOR).

**Design:** ADVANCE is engaging multiple stakeholders, focusing on three project pillars: the Data Pillar will develop and implement plans to normalize, validate, and expand a clinical data repository; the Cohort Pillar will develop and implement systems for engaging patients by collecting patient-reported data; the Regulatory Pillar will streamline existing policies for data security, privacy and confidentiality. ADVANCE’s work will also be supported by the Acuere Quality of Life (AcuereQOL™) data aggregation system to help FQHCs across the country achieve EHR Meaningful Use.

**Setting:** OCHIN, an Oregon-based health information network, Health Choice Network (HCN), a Florida-based health information network and Fenway Health, a Boston-based community health center.

**Participants:** ADVANCE CDRN includes FQHCs in 22 states that serve over 2.3 million patients, mostly women and children, low-income and either uninsured or federally insured.

**Results:** The increased data collection and integration supported by the ADVANCE Clinical Data Research Network will facilitate rich, impactful PCOR. Collecting and integrating multiple sources of data (ambulatory, hospital, claims, patient reported outcomes, and community data) raises many challenges. Some challenges are surmountable while others require workarounds or even changes of scope. Details of these challenges will be discussed.

**Conclusion:** Increasing numbers of FQHCs are embracing quality improvement and research as an integral part of care delivery. ADVANCE is committed to supporting these innovation efforts in FQHCs across the country, and ensuring that PCOR is aligned with the priorities of patients, clinics, and communities in our network.
To be discontinued: CPOE medications orders discontinued with reason being “error (erroneous entry)”

Arbor J.L. Quist¹, Thu-Trang Hickman, MPH¹, Alejandra Salazar, RPh, PharmD¹, Mary Amato, PharmD, MPH², Lynn A. Volk, MHS³, Adam Wright, PhD¹³, David W. Bates, MD¹³⁴, Gordon D. Schiff, MD¹³⁴

1. Brigham and Women’s Hospital, Division of General Internal Medicine, Boston, MA. 2. MCPHS University, Boston, MA. 3. Partners HealthCare, Information Systems, Wellesley, MA. 4. Harvard Medical School, Boston, MA

Background:
The Institute of Medicine estimated that over 1.5 million people are harmed by medication errors each year, making efforts to reduce medication errors important for improving patient safety¹. Implementation of computerized prescriber order entry (CPOE) systems has reduced medication error rates by creating legible prescriptions and incorporating clinical decision support, but these systems may also introduce new types of errors². The FDA funded this study to better understand how CPOE systems may cause medication errors.

Methods:
We examined a previously untapped database of more than 20,000 CPOE outpatient orders discontinued annually with the discontinuation reason “error (erroneous entry)” selected by the clinician. Retrospective review of over 180 instances of medications discontinued for error between 2011 and 2013 uncovered no documentation as to why prescribers made this selection, leading us to design a prospective study to capture first-hand information. We created a program that ran daily to email prescribers who had discontinued a medication clicking (err

Results:
During the four month prospective study period, we sent 542 emails to physicians. They responded to 58% of these query emails (n=312). We categorized the responses using a taxonomy classifying what happened to the patient and what went wrong in the CPOE system³. The top categories of “what happened in CPOE” included medication ordered for wrong patient (19.2%, n=60); wrong drug ordered (12.8%, n=40); and duplicate order placed (9.9%, n=31). Prescriber responses highlighted confusing aspects of the CPOE system and look-alike/sound-alike drugs, and also indicated the differing reasons for selecting “error (erroneous entry).”

Conclusions:
Data regarding erroneous medication entries represent an important source of “intelligence” about how CPOE systems are malfunctioning. Real-time queries to physicians placing discontinuation orders were remarkably more useful than chart review for rich details about reasons for errors in the original orders, with wrong patient and wrong drug errors being leading causes. Wrong patient errors may occur more in CPOE systems than non-CPOE settings as CPOE systems often allow prescribers to have multiple tabs open simultaneously for different patients. Prescribers also need education for better shared understanding of operational definitions for drug discontinuation check-box reasons. CPOE and clinical decision support developers may want to consider designing prompts for optional or required responses to provide details of the reasons when such a check-box category is selected. We found that most medications discontinued in error were discontinued within a minute of order, but future work should include full analysis of time between placing a medication order and its discontinuation to gain a better temporal understanding of when errors are identified and how CPOE interfaces play a role.

Predictors of Medical Records Violation Punishments Filed with the Texas Medical Board (TMB) Before and After the HITECH Act
Mehdi Rais, PhD Student, Kavoos Eilami, MS Student, Craig W. Johnson, PhD
The University of Texas Health Science Center at Houston (UTHealth)
School of Biomedical Informatics, Houston, TX, USA

Introduction: Key Capabilities of EHR’s include health data and information management, results management, orders management, decision support, electronic communication and connectivity, patient support, administrative process and reporting1. Providers have adopted and are using EHRs in their practice settings at high rate since the seminal event of the passage HITECH Act in 2009. With wide-spread adoption of EHRs, changes have occurred in the way with which providers manage their medical records with these new technologies. Researchers hypothesized that such changes in the way with which medical records are maintained would have an impact on a subgroup of disciplinary actions around record keeping with state medical boards. To examine these differences in this virtually non-examined subgroup of disciplinary actions2, this research looked at physician violations due to inadequate medical records as filed with the Texas Medical Board between 2001 and 20143.

Methods: Cases targeted for the study were clinicians with an issued violation by the Texas Medical Board for Inadequate Medical Records occurring between January 2001 and October 2014. A sample of 1353 physician’s records containing characteristics for each individual that included age, gender, birthplace, medical degree, primary specialty, number of specialties, years in practice, and the type of disciplinary actions levied against the provider was obtained from the Texas Medical Board. From this data, it was determined that the two primary punishments issued by the Texas Medical Board were temporary period of probation or permanent license revocation.

Using SPSS 22, we performed hierarchical binary logistic regression and correlation analyses employing model building (1100), and cross-validation (253) samples. The dependent variable was the severity of punishment (Penalty Severity), with punishment being dichotomous (probation vs license revocation). The independent variables were age groups, gender, birthplace, degree type, before or after implementation of HITECH Act, primary specialty, and multi-specialty. Independent variable predictors were categorical in nature. The researchers reliably coded the occurrence/non-occurrence of license revocation versus non-license revocation for all issued violations.

Results: Using backward elimination, we identified age group, birthplace, and multi-specialty to be significant predictors for license revocation. Odds of a license violation recorded between January 2001 and October 2014 resulting in license revocation for inadequate medical records, controlling for other model predictors appear below:

- **Age Groups:** Clinicians in their 70’s had odds of license revocation 6 times those of clinicians in their 30’s; clinicians in their 50’s had odds of license revocation 3 times those of clinicians in their 30’s.
- **Birthplace:** Foreign born clinician had odds of license revocation 2/3 those of US born clinicians.
- **Multispecialty:** Multispecialty clinicians had odds of license revocation 1.6 times single-specialty clinicians.

Conclusions: The variables age, birthplace, and multispecialty have independent predictive value when evaluating license revocations for inadequate medical records. Findings were substantiated by significant (p < .05) odds ratios, Cox & Snell and Nagelkerke R² statistics, as well as significant (p < .001) R² statistics for models’ predicted probability of license revocation versus observed license revocation (Penalty Severity).

Automated Citation Retrieval System for Clinical Knowledge Management

Kalpana Raja, PhD, Andrew J. Sauer, MD, Melanie R. Klerer, Siddhartha R. Jonnalagadda, PhD

1Division of Health and Biomedical Informatics, Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL
2Bluhm Cardiovascular Institute of Northwestern Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Abstract

Novel information retrieval methods to identify relevant citations on a clinical topic can overcome the knowledge gap between scientific publications and online clinical resources. We present a retrieval system that implements PICO framework, Vector Space Model and relevance based ranking module to support clinical knowledge management. The system achieved F-score of over 70% on preliminary analysis compared to baseline F-score of less than 5% and retrieved several new citations for new evidences.

Introduction and Background: The ever-increasing number of scientific publications has posed a challenge in maintaining up to date knowledge summaries in online clinical resources such as UpToDate. Our previous work to provide the best knowledge to clinicians prioritized the journals relevant to a clinical topic. Here we present a citation retrieval system for managing the clinical knowledge available in online clinical resources. Our approach retrieves both previously known citations and potentially new citations, which are not yet cited in online clinical resources, and all citations for new medical topics that are not present in online clinical resources.

Methods: An initial baseline, which is part of our existing system, for a given query is achieved using query expansion with NLM’s E-Utilities. A novel approach using PICO framework is introduced to filter citations with query related intervention or disease name in title and patient information in abstract. The relevance between MeSH (related to query) of citation and query is calculated using Vector Space Model. The citations are ranked based on Journal relevance, MeSH relevance, and VSM relevance.

Results: The input query is an UpToDate article and the output is a list of MEDLINE citations. The performance is evaluated using precision (P), recall (R) and F-score (F) on a gold standard (GS) consisting of citations from the article. The system achieved >70% F-score on a preliminary analysis with three UpToDate articles and retrieved a median of 6 potentially new citations as confirmed by a domain expert. The performance reported by the system is remarkably high when compared to baseline F-score of <5%. A very low precision of 1-2% due to large number of retrieved citations by the baseline decreased the F-score in spite of achieving 70-90% recall.

<table>
<thead>
<tr>
<th>Input query (UpToDate Article)</th>
<th>Citations in Gold standard</th>
<th>System performance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Retrieved citations</td>
<td>New citations</td>
</tr>
<tr>
<td>Anticoagulation in older adults</td>
<td>74</td>
<td>71</td>

<td>58</td>
</tr>
<tr>
<td>The use of antithrombotic therapy in patients with an acute or prior intracerebral hemorrhage</td>
<td>73</td>
<td>76</td>
</tr>
</tbody>
</table>

Discussion and Conclusion: Information retrieval using PICO framework as one of the modules achieved good performance. To our knowledge, PICO framework is used for the first time to filter retrieved citations. The analysis on UpToDate articles reveals that citations without abstract (PMID: 20962419) and MeSH (PMID: 24722803) are not identified by the proposed system. A performance evaluation with additional articles is needed for validating this work on automated maintenance of clinical knowledge in online clinical resources from scientific publications.

Closing the Loop with an Enhanced Referral Management System
Harley Ramelson, MD1, 2, Amanda V. Taube3, Pamela M. Neri, MS3
1Partners Healthcare Systems, Inc., Wellesley, MA, United States; 2Internal Medicine, Brigham and Women's Hospital, Boston, MA, United States; 3Clinical and Quality Analysis, Partners HealthCare, Wellesley, MA, United States

Introduction: Outpatient referrals made by primary care physicians (PCPs) involve multiple sequential steps requiring provider-to-provider and provider-to-patient communication. Analysis of malpractice claims has shown that the referral process in the ambulatory setting is prone to incomplete follow-up and communication break-down. An enhanced electronic referral management system (ERMS) was developed in an ambulatory EHR to meet a series of best practice steps for referral management. The objectives of this study were to assess PCP and staff satisfaction with the ERMS and to evaluate whether PCPs and their practice staff would find it easier to complete individual steps in the referral process and whether they would find it easier to identify when a problem has occurred in the process.

Methods: The ERMS was launched in two separate releases in 2014. The first release focused on functionality to create, transmit and track referrals as well as the ability to indicate that a referral was complete (“close the loop”) and to identify when a referral was overdue. The second release primarily focused on a series of reports allowing retrospective analysis of referral patterns. This study enrolled nine ambulatory primary care practices affiliated with an integrated delivery system in the Northeast. Approximately 100 practice staff members, including physicians, medical assistants, nurses, and administrative staff involved in the referral process were recruited across these practices to participate in surveys and interviews conducted pre-and post-implementation of both releases. Data reported here reflect results of the surveys conducted at baseline and following the first release. Ease of use and usefulness of specific functions were evaluated on a five-point Likert scale while satisfaction was evaluated on a seven-point scale.

Results: In the first 5 months following the release of the new ERMS module in the EHR, almost 3000 total referrals were generated. At baseline, 74% reported that it was easy or fairly easy to create a referral. This increased to 91% on the follow-up survey. At baseline, 33% reported that it was easy/fairly easy to schedule an appointment with a specialist. This increased to 64% on the follow-up survey. At baseline, the percent who reported that it was easy/fairly easy to identify when an appointment was not made with the specialist, when an appointment was missed or when an appointment was cancelled was 34%, 22% and 12% respectively. These increased on the follow-up survey to 54%, 45% and 36%, respectively. When asked about their overall satisfaction with the referral process, 36% of respondents reported they were satisfied or very satisfied at baseline compared to 92% at follow-up. The new functionality was also assessed in the follow-up survey to determine the usefulness of 15 major new functions in the module. Nine functions were found by 90% or more of respondents to be useful or somewhat useful. These include: 1. Ability to refer to a practice in addition to an individual specialist 2. Search functionality for a specialist 3. Favorite list of specialists and practices to whom PCPs commonly refer their patients. Supporting the intra-practice workflow of a staff person creating the electronic referral and sending to the PCP to authorize 5. Ability of the system to automatically fill in the appointment date based on interfaces with scheduling systems 6. Ability of the system to automatically link the specialist’s consult note to the referral based on the linkage with the notes module in the EHR 7. Ability of the system to identify when a referral is overdue at various stages in the referral life cycle 8. Ability to acknowledge the consult note in the referral module 9. Ability to document the closing of the referral. Conclusions: The results from the surveys after the new release of the ERMS show there is an increase in user satisfaction with the referral process and that most of the functionality was considered to be useful by a majority of the respondents. Users of the module found that previously difficult tasks such as the ability to identify when an appointment with the specialist was not made, missed or cancelled became easier with the new module. The implications for quality of care and patient safety are clear: when practice staff are able to track referrals in a more effective and efficient way and be able to intervene when appropriate, fewer patients will experience delayed specialty care potentially leading to improved patient satisfaction and patient safety.

Problem list problems: A look into data integrity

Gilbert H. Ramirez, M.D., Hyeon-eui Kim, R.N., Ph.D., M.P.H., Robert E. El-Kareh, M.D. M.P.H., M.S.

1University of California- San Diego, San Diego, CA

Abstract
Maintaining accurate problem lists for patients can be important for patient care, driving clinical decision support and identifying appropriate cohorts for research. However, problem lists are often inaccurate and out of date. We took the problem list data from 32,965 patients in our medical system and described issues with their data integrity.

Introduction
Accurate problem lists in electronic health records can support fast and efficient clinical care, clinical decision support and identification of research cohorts. We sought to look at the data integrity of these lists at our institution.

Methods
We created descriptive statistics for the types of providers who entered and revised problems, durations of problems before resolution and number of duplicates on the problem lists. As an example of an acute issue, we describe how long “urinary tract infection” remained on problem lists.

Results
Our preliminary results show 4941 (15%) patients with duplicate problem list items, which may be a considerable underestimation as we did not account for similar ICD codes in the initial analysis. We also found that only 5% of problem list items were resolved overall. For urinary tract infection, the average time to resolution in the problem list was 859 days 95%CI (753.16 to 964.84).

Preliminary data on those modifying problem list data (Figure 1)

![Figure 1. Types of providers modifying data in the problem list.](image)

Conclusion
Our preliminary data shows that attending physicians update problems most often, but these lists are inaccurate or out-of-date for many acute issues. Further study of practice style and data entry habits will help identify solutions.
Automating Maintenance of Care Team Relationships from Electronic Health Administrative Data to Decrease Variability of Care Coordination using the Health Information Exchange Infrastructure

Pallavi Ranade-Kharkar, PhD, MS1,2, Greg Gurr BS3, Darren Mann BS1,
Sidney N. Thornton, PhD1,2
1Intermountain Healthcare, Murray, UT; 2Department of Biomedical Informatics, University of Utah, Salt Lake City, UT; 3Agilex Technologies Inc., Chantilly, VA.

Abstract
Primary care physicians refer one in three patients to specialty care. Yet, care coordination between primary care and specialty care lacks adequate information transfer and referral tracking. We propose an intervention that analyzes electronic health administrative data, extracts and curates relevant care team relationships and uses the health information exchange (HIE) infrastructure to automate care coordination for specialty care referrals enabling rule-based, standardized clinical data transmission.

Introduction
An integral aspect of care coordination is the “exchange of information among participants responsible for different aspects of care”1. For effective care coordination, the health system must understand the who, when, what and how of information exchange. Automation can reduce variability associated with manual processes2. Communication between primary care physicians and specialists is often inadequate, late and/or missing in about half of the referrals3. Insufficient time and logistical barriers were cited as hindrances for less than desired level of communication. Poor referral tracking and information transfer can lead to wasteful re-referrals, delays in diagnosis or treatment, diminished patient and physician satisfaction and poor quality of care. Intermountain Healthcare (IH) has built multiple connections for health information exchange (HIE) with state and national-level partners with interposed services that provide a platform for authoring logical processes for bi-directional data transmission.

Method
We created a system to process real-time health administrative data from multiple source systems, to link relevant patient visits, and to create a list of potential recipients responsible for different aspects of patient care within our trust framework. We curate this list based on patient’s current visit reason and create a distribution list of care team members. We have extended the existing HIE infrastructure to: 1) create triggers by intercepting the multi-source HL7 ADT transactions; 2) derive a care team of clinicians based on the incoming data and a rules repository that defines what relationships are pertinent; 3) build subscription services for clinicians to specify their preferences for types of documents of interest and frequency of exchange; and 4) send the requested document to the members of the curated care team using the HIE infrastructure at a pre-determined time and/or interval based on the visit context.

Results and Discussion
Building relevant care team relationships from source systems in addition to our EHR enables care coordination across organizational boundaries. Our approach to repurpose the HIE infrastructure to automate the communication between primary care and specialty care for referrals reduces the variability of information transfer by providing just-in-time and consistent solution that does not require manual intervention. The ability to subscribe/unsubscribe delivery preferences gives autonomy to clinicians to fit the type and frequency of communication to their needs.

Conclusion
Rule-based automation of data transmissions supporting care coordination eases the operational burden of busy clinicians and offers a predictable workflow. Creation and curation of relevant care team relationships from past and current administrative data provides a reusable resource that can enable additional service development.

Children's National Medical Center, Washington, DC

Introduction

Electronic prescribing (eRx) directly to pharmacies is associated with increased fill rates, improved clinical outcomes, decreased medication errors, and cost savings1,2. The Centers for Medicare and Medicaid Services includes eRx in the meaningful use criteria used to evaluate hospitals and providers. Studies suggest that non-physician providers (NPPs) provide equal or better care compared with physicians3. However, adoption rates of eRx by NPPs compared to physicians are not known.

Objective

To determine if non-physician providers e-prescribe at higher rates than physicians in a pediatric emergency department (ED).

Design/Methods

Retrospective analysis of discharge prescriptions from 2 pediatric EDs between 12/2013-10/2014 after implementation of a commercial eRX platform. Prescriptions without a designation of print or eRx were removed from the analyses (1.3%). Bivariable and multivariable regression analyses were used to determine associations between provider type and eRx status. Covariates included shift, day of week, calendar quarter, location (hospital ED vs. satellite ED), and medication type. Analyses included physicians (pediatric emergency medicine (PEM) attendings, general pediatricians, and fellows) and NPPs (nurse practitioners and physician assistants).

Results

There were 45,752 prescriptions from 128 ED providers: 33% eRx and 67% printed. NPPs and physicians had eRx rates of 41% and 31%, respectively (OR 1.5, 95% CI 1.46-1.61). The difference remained significant after adjusting for covariates (aOR 1.6, 95% CI 1.56-1.73). Daytime shift (7am-3pm) (aOR 1.4, 95% CI 1.31-1.47), Tuesday (aOR 1.2, 95% CI 1.11-1.29), and satellite ED (aOR 2.4, 95% CI 2.33-2.54) were associated with greater eRx rates. Oral antibiotics and NSAIDs accounted for 47% of the total prescriptions and had eRx rates of 37% and 28% (aOR 1.6, 95% CI 1.54-1.74). PEM attendings prescribed 13,917 of the total prescriptions; those with 5 years or more experience eRx at 41% and those with <5 years experience at 31% (aOR 1.7, 95% CI 1.56-1.84).

Conclusion

Non-physician providers e-prescribe more frequently than physicians. This difference may reflect more rapid adoption of new technology by non-physicians and is an area that deserves further investigation. In addition, if these increased eRx rates by non-physicians prove true in multiple settings, it may suggest utilizing non-physician groups as champions of eRx and targeting additional educational efforts at physicians. Daytime shift, Tuesday, satellite ED, and PEM attending with 5 years or more experience were all associated with higher rates of e-prescribing. We had expected more senior PEM providers to have lower eRx rates and were surprised to find the opposite. Future studies could explore this issue and qualitatively assess the factors and medication types associated with different eRx rates.

Social Media use for Drug Repurposing: Understanding the consumer perspective

Majid Rastegar-Mojarad, MS12, Hongfang Liu, PhD1, Priya Nambisan, PhD2
1Department of Health Sciences Research, Mayo Clinic, Rochester, MN; 2Department of Health Informatics and Administration, UW-Milwaukee, Milwaukee, WI

Introduction
Drug repurposing is the process of discovering new indications for existing drugs and is becoming an important component of drug development as success rates for novel drugs in clinical trials decrease and costs increase. In the period 2007-2009, drug repurposing led to the launching 30-40% of new drugs. Typically, a new indication for an available drug is identified by accident. However, new technologies and huge amount of available resources enable us to develop systematic approaches to identify and validate drug repurposing candidates with significantly lower cost. A variety of resources have been utilized to identify novel drug repurposing candidates such as literature, clinical notes, and genetic information. Another valuable resource in drug repurposing is patient experience and incidence of consumer drug repurposing. Social media is providing a platform for patients to share their experience with their illness and medications. One example of such drug repurposing by consumers through social media, is the use of Stilnox, an insomnia medication for brain injury. These kinds of consumer drug repurposing happens in many online forums and good examples of such forums are PatientsLikeMe and WebMD, both allow patients to freely share their experience with their treatment and medications. However, there haven’t been any studies to understand how and what kinds of drugs are being repurposed by patients in these online forums. In this study, we are focusing on WebMD to identify all events of drug repurposing.

Materials and Methods
First a list of commonly searched drugs in WebMD is retrieved. For each drug, we retrieve 1) known indications from DrugBank 2) side effects from a side effect resource called SIDER 3) patients’ reviews in WebMD which contain at least one disease name (except known indication and side effect). The list of disease names is retrieved from UMLS and finding disease name in the reviews is done by co-occurrence search. For the drugs with low number of retrieved reviews, we manually analyze them. For the rest, we implement a code to automatically detect patterns such as “I use drug for disease”. Each review has three rates a) Effectiveness b) Ease of use c) Satisfaction, and some information about the reviewer such as age, sex, and how long on treatment. This information uses to classify and prioritize the reviews.

Results
We started a list of 180 top searched drugs in WebMD. The average of number of reviews for each drug is 751. The maximum number of reviews is for Cymbalta with 4433 reviews and the minimum number is 41 reviews for Hydrocodone HD. Our initial analysis showed in 1800 reviews (10 for each of the drugs), 472 unique disease names (some of them are false positive because of disambiguation), 2973 mentions of disease names. The most frequent disease name is depression with 133 appearances in the 1800 reviews. Some of the other frequent disease names are migraine, itching, rash, arthritis, and dry mouth.

Implications
When patient use social media to share their experience with medication, most of time they talk about effectiveness of medications or side effect. Sometimes they share experience of using a medication for not FDA-approved indication. In this study, we try to identify these comments and detect the new indications. There are some limitations in this approach. First, this type of findings is not for serious and long-term diseases. In fact, patients can’t recognize effect of unrelated medication on a long-term disease. Second, as the reviews are informal comments and they contain misspelling and grammatical errors, developing a Natural Language Processing (NLP) system to analyze the text automatically is problematic. The first step in developing the NLP system is implementing a disease named entity recognition (NER). For obtaining preliminary results, we used a simple dictionary-based NER, in which false positive rate are high because of disambiguation. Some examples of disambiguation are: ‘still’, ‘down’, and ‘little’ which could also be disease names. Solving this issue in formal text with proper grammar and spelling is relatively easier than informal reviews in social media written by non-expert people. We plan to use machine learning NER. To assess the feasibility of using social media for drug repurposing, we will review the comments manually.
Web-based Patient-Centered Toolkit: Demographics of Enrollment

Sucheta S. Ravindran, MS, 1 Anuj Dalal, MD, 1,2 Conny Morrison, 1 Julie Fiskio, 1 John Hanna, 1 Diana Stade, 1 Kelly McNally, 1 Eli Mlaver, 1 Patricia C. Dykes RN, PhD 1,2 1 Brigham and Women’s Hospital, Boston, MA, 2 Harvard Medical School, Boston, MA

Introduction: In busy acute care settings, the utility of bedside patient portals for engaging patients in their care has great potential for enhancing patient education, facilitating communication with providers, and improving the patient experience. 1 With a diverse patient cohort in mind, we implemented a web-based patient-centered toolkit (PCTK), optimized for standard-sized tablet computers (e.g., iPads). The PCTK was designed to be easily usable by patients and caregivers, regardless of prior exposure to tablet functionality. 2 In performing this analysis, we aimed to analyze patient demographics by enrollment status (enrolled vs. declined to enroll), and to identify correlations between patient participation and key demographics.

Method: Patients admitted to medical intensive care and oncology units were approached for enrollment during the study intervention period. Demographic information, including age, race, gender, and education level, was retrieved from the electronic health record. We compared average age of enrollees versus non-enrollees using the t-test method. We measured correlations between demographic markers and patients’ willingness to participate using Spearman rho test. We calculated frequencies of various educational levels for enrollees and non-enrollees. These data were analyzed to identify differences between patients who participated and those who declined.

Results: Of 410 patients approached, 147 patients enrolled and 263 patients declined to participate. The average age of all patients was 58.5 ± [15.98] years; 240 (58.5%) were male; 308 (75.1%) were Caucasian; and 102 (24.9%) were non-Caucasian. The average age of patients who declined compared to that of enrollees was 60.5± [15.6] versus 54.9± [16.1] years [p = 0.0001]. There was a weak but statistically significant negative correlation between age and participation in use of the bedside toolkit (Spearman rho = -0.167; p = 0.001; alpha = 0.01). One-hundred and seventy-eight (43.4%) patients were graduates of college or postgraduate school, 82 (20%) had some college or vocational schooling, 114 (27.8%) were high school graduates or had a GED, and 17 (4.1%) had some high school education. Of the 147 enrollees, 90 (61.2%) were graduates of college or postgraduate school, 30 (20.4%) had some college or vocational schooling, 24 (16.3%) were high school graduates, and 3 (2%) had some high school education or less. Of 263 who declined to enroll, 90 (34.2%) were high school graduates/GED, 88 (33.5%) were graduates of college or postgraduate school, 52 (19.8%) had some college or vocational schooling, and 33 (12.5%) had some high school education or less. The most common reason why patients declined to enroll was a self-reported lack of need (110 patients; 41.8%). Other common reasons for declining were that patients did not speak English (42 patients; 16%) and that patients felt the toolkit involved “too much technology” (15 patients; 5.7%). Ninety-six patients (36.5%) declined for other reasons.

Discussion: In designing technology-driven bedside tools, accessibility and ease of use are important considerations, especially given diversity in patient demographics. In spite of tailoring our tool with a diverse patient population in mind, lack of previous experience or familiarity with bedside tools and personal willingness to participate are potential barriers to using technology as a means of engaging in one’s plan of care. Our analysis shows that the largest proportion of patients who both enrolled and declined enrollment had the highest education level. This is consistent with our finding that the majority of the patients approached was more educated. It is thus apparent that an analysis of a larger and more representative patient population might generate further insight into the goals of this particular study. Our results, however, do shed some light on important considerations for the use of informatics as a tool for improved patient engagement. Though we found a negative correlation between toolkit enrollment and age, it was not as strong as anticipated; in fact, this finding indicates greater success at enrolling older patients than initially expected and suggests more potential for varied enrollment. With regard to education, our findings suggest that, particularly with less educated patients, perhaps presenting the toolkit as a means of more actively engaging in one’s care plan may result in greater willingness and an improvement in patients’ perceptions of their need to utilize the toolkit in the future.

Acknowledgments: The BWH PROSPECT study is funded by the Libretto Consortium supported by the Gordon and Betty Moore Foundation

Gaussian Processes for interpreting Multiple Prostate Specific Antigen
measurements for Prostate Cancer Prediction

Narges Razavian\textsuperscript{PhD,1}, Saul Blecker\textsuperscript{MD,2}, David Sontag\textsuperscript{PhD,1}

\textsuperscript{1}Computer Science Department and \textsuperscript{2}Medical School, New York University, New York City

Background and Introduction:
Prostate cancer is the second leading cancer cause of death among US men. Prostate Specific Antigen (PSA) is currently the primary approach used for prostate cancer screening, but the recommended cutoff (\( \geq 4.0 \text{ng/mL} \)) is limited by low sensitivity\textsuperscript{1}. In this work, we present a machine learning approach based on Gaussian processes\textsuperscript{3} that is able to better use repeated PSA measurements in detecting prostate cancer. Gaussian Processes are semi-parametric methods, which use a distance measure to construct a kernel matrix and approximate a function from possibly noisy and irregularly measured observations. They enable inference of the function value at new data points, and provide confidence of the inferred values.

Methods:
We use an initial cohort of 4.1 million beneficiaries, enrolled in a major insurance company between 2005 to 2013. We included male beneficiaries age\( \geq 50 \) who had at least two PSA readings. The primary outcome was prostate cancer, defined by a prostate cancer diagnosis, AND either having at least one PSA measurement\( > 10 \text{ng/mL} \), or having gone through cancer treatment (bilateral orchiectomy, chemotherapy, cryotherapy, external beam radiation therapy, prostatectomy, radioactive seed implants, brachytherapy, or hormone therapy). A male patient was defined not to have cancer if no evidence of any prostate cancer (diagnosis or treatment) or PSA\( > 10 \) were ever observed in their records. We excluded patients who were not in our positive or negative class. We used as the index date (i.e., the “prediction time”) the first date at which a patient was observed to have a PSA of above \( 4.0 \text{ng/mL} \), or before the time of the cancer diagnosis (the earliest of these two dates). We used PSA values and velocity feature using slope of the \( \log(\text{PSA}) \) over the past years\textsuperscript{3}. We then use two methods of linear regression (in log space), and Gaussian processes(with linear and cubic kernel functions)\textsuperscript{2}, to transform PSA observations to a fully observed time series, and classify the time series using logistic regression and support vector machines. We train the models using randomly selected 60% of the data. We use 20% of the data to tune parameters of the model, and use the remaining 20% as the validation set.

Results and Discussion:
Of the patients that matched inclusion criteria, 1018 developed prostate cancer. Table 1 shows the quality of the cancer detection for different methods. Our results confirm previous findings that multiple observations of the PSA values improve the prediction sensitivity\textsuperscript{4}, while retaining high specificity. However, we conclude that interpreting the multiple observations is important. Velocity features\textsuperscript{3} help with the sensitivity, however they suffer from low specificity. By using Gaussian process (both linear and cubic) we can improve the downstream cancer classification accuracy. Two major classifiers (SVM and logistic regression) show similar quality for classification, with logistic regression model slightly better, but our major gain was achieved from better modeling of patient’s all previous PSA observations.

Identification of Variables that Predict Visit Times for Analyzing Ophthalmology Clinic Workflows

Sarah Read-Brown\textsuperscript{1}, Michelle R. Hribar, PhD\textsuperscript{2}, Grant Aaker, MD\textsuperscript{1}, Leah Reznick, MD\textsuperscript{1}, Thomas Yackel, MD, MPH, MS\textsuperscript{2}, Michael F. Chiang, MD, MA\textsuperscript{1,2}

\textsuperscript{1}Ophthalmology and \textsuperscript{2}Medical Informatics & Clinical Epidemiology; OHSU, Portland, OR

Introduction
Patient flows in clinical ophthalmology are complex and multifaceted which leads to the accumulation of patient wait times, affecting patient satisfaction\textsuperscript{1} and future care\textsuperscript{2}. Being able to predict variability and patient exam times has potential to greatly improve scheduling strategies\textsuperscript{3}. We propose using observational data, electronic health record (EHR) data, and provider’s perceptions of patients to identify variables that predict visit lengths.

Methods
This study took place at OHSU, in a single ophthalmology provider’s clinic (LR). Two authors (SRB, MRH) observed a clinic for 8 days, using time motion methods and electronic forms to record the times that patients spent during each part of their exam. After each exam, the provider was asked to categorize patients as complex vs. non-complex in regard to their medical diagnosis and encounter interactions with the provider. We then combined observed times and perceptions with timestamps and patient characteristics recorded in the EHR (Epic; Verona, WI). We calculated the length of the total interaction time with the provider and staff (total exam time) as well as the total length of the office visit (total visit time). The total visit time includes the total exam time plus wait times.

Results
Table 1 shows the total exam and visit times based on provider perception, age category, and dilation. The factor that most strongly predicted total exam time was the provider’s perception of a complex vs. non-complex encounter. The factor that most strongly predicted total visit time was dilation.

Table 1. Influence of various factors on mean total exam time and total visit time

<td>66 (100%)</td>
<td>27</td>
</tr>
</tbody>
</table>

Conclusion
Secondary use of EHR timestamps and observed clinical data can help understand workflow by predicting exam time and wait time, and may be used to increase office efficiency in scheduling. In addition to traditional patient demographics, provider perception may be a useful indicator of the total exam and total visit times.

Novel Template Identification from VA Text Integration Utility Notes

Andrew M. Redd, PhD1,2, Guy Divita, MS2,3, Adi V. Gundlapalli, MD, PhD1,2, Le-Thuy Tran, PhD2, Mathew Samore, MD1,2

1Division of Epidemiology, Department of Internal Medicine, University of Utah; 2IDEAS Center, VA Health Care System, Salt Lake City, Utah; 3Department of Biomedical Informatics, University of Utah;

Abstract
Templates in text notes pose challenges for information extraction. We are developing a system that identifies novel templates in plain text notes included in Veterans Health Administration (VA) Text Integration Utility (TIU) notes. The system is comprised of two parts. The first clusters documents according to groups that are likely to have been derived from the same template. The second attempts to identify elements of the template from these documents.

Introduction
For the purpose of this project we define template to be a set of textual elements where additional information is inserted by a care provider. A common example of this kind of template would be a form for recording a patient’s vital signs, heart rate, blood pressure, etc. Templates pose a particular challenge for information extraction (1). For example, templates can cause an excessive number of false positives (2). These challenges were the inspiration for developing a tool that identified templates without the assumption of knowing the form or content of the templates.

Previous Work
The most relevant work that relates to this are algorithms related to plagiarism detection including detecting copy and paste sections. Also a relevant area of research is document section identification which overlaps in the goal of trying to tag information to text.

Methods
The system we are developing separates the process into two parts. First we identify groups of documents that are similar, with the premise that these documents are likely to contain the same template. To accomplish this, documents are tokenized on whitespace, case sensitive with punctuation attached to the word if there is no whitespace between. To handle the large number of tokens possible, tokens are reduced using cyclical redundancy check as a many-to-one dimension reduction map, with 512 possible bins words could be grouped into. Hashed tokens are counted and a hierarchical clustering algorithm used to create groups. The logic behind this is that documents created from the same template will show similar token counts.

The second process takes groups of similar documents and extracts the relevant templated text. Under the assumption that templates are text with other text inserted, if all the documents in a group do indeed contain the same template, the common elements of all documents are likely to be the template. We implemented a longest common subsequence (LCS) to extract the elements of documents that were common to all documents and in the same order in all documents.

Results and Next Steps
We applied the methods to a 750 document corpus, a random selection of notes from many different note titles, and will present results. We are scaling the methods to run on a larger corpus with approximately one million documents. This will result in a new catalog of templates with statistics regarding use across documents and type of use, in addition to being able to be used as a tool for identifying documents that use the template. The long term goal is to complement ongoing efforts in improving information extraction techniques for VA big data.

Preserving Semantic Content of Narrative Clinical Information in the OMOP Common Data Model Format

Grant Reed, PhD and Carol Friedman, PhD
Department of Biomedical Informatics, Columbia University, New York, NY

Abstract

To date, little research has been performed on how to preserve the semantic content of relevant clinical information that is contained in narrative clinical notes, while representing the information in the format of a common data model, such as the Observational Health Outcomes Partnership common data model (OMOP CDM).

Introduction

In order to detect adverse event signals, effective pharmacovigilance research requires a vast amount of clinical patient data. A common data format facilitates the analysis of large data sets from disparate data sources. For example, Observational Health Data Sciences and Informatics (OHDSI) researchers utilize clinical information originating from claims data and electronic health record data, which is mostly structured, that has been transformed into OMOP CDM format. However, common data models are typically constructed to accommodate fairly simple structured clinical data, not fine grained structured data obtained from narrative clinical information, which is semantically rich and includes many different types of modifying information. As a result, there is potential for loss of semantic content upon transformation into the CDM format.

Methods

We converted narrative clinical notes to structured content using MedLEE, which is a natural language text processor that captures comprehensive clinical information that includes qualifiers such as certainty, severity, temporal information and family history. We then established how to represent the rich structured form in the OMOP CDM format. One aim was to compare the data content of the structured data obtained from natural language processing to the type of data content that is accommodated by the OMOP CDM. A second aim, which is future work, is to tailor the extraction-transformation-load (ETL) in a manner that minimizes loss of semantic content.

Of particular interest is how to preserve the broad range of qualifiers found in narrative clinical text in the OMOP CDM format. For example, certain qualifier types of information can be stored in the OMOP CDM Observation table, as foreign keys to standard concept identifiers corresponding to qualifiers. However, what must be determined is whether or not the fields can accommodate the complexity and comprehensiveness of qualifier information contained in the rich structural form of MedLEE output. Also of interest will be to demonstrate that the fine grained data is useful in pharmacovigilance research.

Conclusion

This research should preserve semantic content in narrative clinical data upon transformation into the OMOP CDM format, and should be useful for increasing the amount and richness of clinical information available to OHDSI researchers. This research may also lead to recommendations for enhancing the CDM format to accommodate more complex data useful in pharmacovigilance research.

Adapting a Mobility Monitoring Protocol for Sensor Studies with Functionally Vulnerable Older Adults

Blaine Reeder, PhD¹, Angela Richard, PhD, RN¹, Jason Falvey, PT, DPT¹, Roger Paxton, PhD¹, Jennifer Stevens-Lapsley, PT, PhD¹
¹University of Colorado | Anschutz Medical Campus, Aurora, CO

Introduction
Mobility is a strong predictor of hospital readmission in older adults after acute hospitalization. However, little is known about the mobility levels of this population after discharge home. In-home sensor technologies have great potential to monitor mobility levels in support of independence for older adults. However, some older adults live with multiple morbidities that limit their capacity to engage in research. This challenge has resulted in few large-scale sensor studies that enroll older adults. Therefore, the purpose of this presentation is to describe how we adapted a mobility monitoring protocol previously employed with healthy community-dwelling older adults to reduce participant burden for functionally vulnerable older adults that enroll in sensor studies.

Methods
Adaptation of the mobility monitoring protocol to a short form was informed by experiences from a feasibility study with functionally vulnerable older adults who received a progressive multi-component (PMC) physical therapy intervention after discharge home from an acute hospitalization. The original mobility protocol totals 74 items and comprises physical, psychosocial, and cognitive parameters intended to correlate self-reported and sensor-based measures of mobility. We used the PMC protocol as criteria for instrument substitution to reduce the total number of participant-completed items in these parameters.

Results
Instrument replacements reduced the total number of items from 74 to 43, a total reduction of 31 items. Table 1 shows specific changes made for physical and psychosocial parameters. No changes were made for cognitive parameter measurement. Monthly paper fall calendars were replaced with a single weekly Y/N question about falls or near-falls using a tablet computer. Two semi-structured technology interviews (60-90 minutes), at study midpoint and end, were replaced with a 15-question technology acceptance survey and a short interview (30 minutes), to be administered at study end.

Conclusion
Our next steps are to pilot the short form mobility monitoring protocol in a feasibility and acceptability study that tests the use of in-home sensors in support of a progressive multi-component physical therapy intervention for functionally vulnerable older adults. The authors would like to thank Drs. Hilaire J. Thompson and George Demiris from the University of Washington as the originators of the original mobility monitoring protocol.

Identifying Patterns Indicative of Copying/Pasting Behavior in Patient Generated Online Content

Tera L. Reynolds, MPH,1 V.G.Vinod Vydiswaran, PhD,2,4 Yuting Wu,3 Qiaozhu Mei, PhD,1,4 David A. Hanauer, MD, MS,5,1 Kai Zheng, PhD6,1

1School of Information; 2Department of Learning Health Sciences; 3College of Literature, Science, and the Arts; 4Department of Electrical Engineering and Computer Science; 5Department of Pediatrics; 6School of Public Health Department of Health Management and Policy. University of Michigan, Ann Arbor, MI

Background
Providing patients with ready access to, and ownership of, their clinical information (e.g., laboratory results, discharge summaries) through technologies such as patient portals has been a much anticipated paradigm shift in healthcare. However, existing research provides evidence of several barriers to the adoption and use of patient portals, with one of the primary barriers being low numeracy and poor health literacy among patients.1 Online health forums provide an opportunity for researchers to gain insights into the questions that patients ask about clinical information on peer-to-peer communication channels, which is indicative of the struggles that they may have in understanding the information. The types of questions posted in online health forums vary greatly; from requesting emotional support to posting detailed clinical information that appears to be copied and pasted or transcribed (referred to below as copying/pasting behavior) directly from a patient’s medical record (e.g., laboratory results). In order to further study the challenges that may arise when patients are presented with clinical information, we considered the latter type of question and, as an initial goal, focused on identifying instances of copying/pasting behavior related to laboratory test results.

Methods
We downloaded all questions and threaded comments from a popular online health forum, MedHelp.org, in February 2013. The full dataset contains 1.4 million questions and 4.6 million answers/comments generated by over a million unique users on various health-related topics. We utilized the live MedHelp.org website in the development and testing of various keyword searches (e.g., “Lab result help”) by viewing 90 posts of the results of each search for: (1) the number of instances of copying/pasting behavior, and (2) the “Related Discussions” section for additional words/phrases to test. We then translated the keyword searches with the highest proportion of relevant posts to complex queries in the Indri Query language.2 The queries were run against an inverted index built over all the MedHelp.org question posts. We manually reviewed the top 20% (600) of the retrieved results to identify patterns indicative of patient copying/pasting behavior. During the review of the last 100 results, no additional general patterns were added, suggesting saturation had been reached.

Results
Among the MedHelp.org question posts with evidence of copying/pasting behavior (n=184), seven general patterns were identified: (1) 93% specific test name and numeric result (e.g., TSH 0.11), (2) 47% lab normal/reference range, (3) 38% “results below”, (4) 27% units (e.g., 1000.0 IU/L), (5) 23% specific test name and categorical result (e.g., HCV RNA: Positive), (6) 16% tabular, and (7) 4% quotation marks (e.g., “Herpes simplex type 2 isolated”).

Conclusion and Future work
We identified several patterns indicative of patient copying/pasting behavior in a popular online health forum. We intend to continue this work by: (1) comprehensively extracting all instances of copying/pasting behavior, (2) searching for themes in the extracted posts in an effort to better understand the underlying questions in the posts, and (3) based on this understanding, suggesting ways to improve patient portals to help patients better understand their data. In addition, future research may include developing methods to identify instances of copying/pasting behavior from other sources of clinical information (e.g., discharge summaries and clinical notes).

An Analytics Approach for Adverse Drug Event Discovery

Mohammadreza Rezaie1, Kenji Yoshigoe, Ph.D.2, Umit Topaloglu Ph.D.1
1Division of Biomedical Informatics, University of Arkansas for Medical Sciences, Little Rock, AR; 2Department of CS, University of Arkansas at Little Rock, Little Rock, AR

Abstract
Healthcare organizations generate massive quantities of data which are often convolved with valuable hidden insights. In order to discover new adverse drug events (ADEs) the data mining techniques are employed extensively, but the computational complexity of the traditional data analytics platforms makes the need to migrate to a scalable analytics platform. The goal in experiments was predicting the possibility of certain interactions given a prescribed set of drugs. In this work, we used Spark platform and MLlib library as an alternative scalable solution that we found them scalable, easy to work with and with reasonable modeling accuracy.

Introduction
Discovering the drug adverse effects in both trial and post marketing phase is important for patient safety and efficacy of drugs. Data mining and predictive analytics proposes a promising solution to deal with this task. From the predictive analytics perspective, the goal is to predict the possibility of different symptoms given a prescribed set of drugs. However, due to the massive scale of the dataset, the traditional analytics tools and methods are no longer applicable or very time consuming. Magnitude of data (e.g. the FDA Adverse Event Reporting System [FAERS] dataset) to be analyzed urges us to exploit big data technologies and platforms, such as NoSQL.

The FAERS dataset contains patients’ demographic and drugs usage history information along with the symptoms associated with their prescription. We propose a prediction model, which attempts to find correlations between drugs and drugs to symptoms. The model is then used to predict the chance of exposure to different interaction given a prescription. It also generates alerts in case that the probability is higher than preset threshold value.

Our approach
We utilized Apache Spark to process the data and MLlib to perform the predictive modeling task. Spark is a parallel computing framework that is well suited for processing the large scale distributed data on large clusters. MLlib is a machine-learning library developed on top of Spark and contains many widely used algorithms for predictive modeling and data mining. We prepared a dataset from the most seen interactions and drugs in FAERS dataset (the top 10 interactions and top 30 drugs, based on their popularity) and imported it into Spark with a readable format for MLlib.

The result of many experiments we conducted on the dataset, proved to be promising. We have run Naive Bayes, Decision Tree and Random Forest Classifiers on the FAERS dataset and the Random Forest performed better in accuracy with 75.99%. The measure of accuracy here is the mean of correctness of interactions predictions compared against the model trained over 60% of data, and tested on the remaining 40% in a cross-validation type of analysis.

Conclusion
Predicting possible interactions between drugs over the FAERS dataset is crucial for the post-marketing surveillance program. The large size of dataset can result in high computational complexity that might not be tolerable for traditional data analytics tools. That fact strengthens the argument for the use of Spark and MLlib as a reasonable choice for predictive modeling. Throughout our experiments, we found Spark and MLlib to be scalable, easy to work with and well documented.

Visualizing High Dimensional Clinical and Tumor Genotyping Data

Matthew J. Rioth, MD1,2, Jeremy L. Warner, MD1,2
1Vanderbilt Department of Biomedical Informatics, Nashville, TN; 2Division of Hematology/Oncology Vanderbilt University Medical Center, Nashville, TN

Introduction

The increasing use of next-generation sequencing in the treatment of cancer produces multiplying amounts of genotyping data1. However, the representation of population-level genotyping data within a clinical context for operational, quality-improvement, and research purposes is difficult given their high-dimensionality and poly-hierarchical representation2. We describe novel interactive visualizations of these data that make them more intelligible, intuitive, and useful.

System description

We utilized data from targeted exome tumor sequencing results transmitted from a 3rd-party laboratory, in a standardized extensible markup language (XML) format. These XML documents were parsed for clinical as well as genomic data and aggregated into a relational database to enable population-level depiction for secondary uses. The data contained in this database were depicted with interactive visualizations using off-the-shelf data analytics products as well as custom scripted interactive web-based documents. The utility of these visualizations are becoming apparent to clinicians, administrators, and researchers and we are continuously improving and refining them based on feedback and evolving needs.

Figure 1. Example interactive bubble-plot visualization of population level genetics across tumor types.

Automated Prediction of Human Mobility Patterns in International Humanitarian Response

Nicholas Robison¹,², Anne M. Turner, MD, MPH, MLIS¹,²
¹Division of Biomedical and Health Informatics, University of Washington, Seattle, Washington
²Department of Health Services, University of Washington, Seattle, Washington

Introduction: Over the past decade international response to humanitarian emergencies has increased in its operational complexity involving the collaboration of multiple organizations, governments, and private individuals to provide supplies, infrastructure, and aid workers to address the emerging crisis. However, the amount of information regarding population dynamics, available resources, and immediate needs, made available to these responders is severely limited and has not kept up with changing needs. One particulate challenge is in understanding the underlying dynamics and distribution of affected populations. After a disaster, populations go through a period of tremendous fluctuation and realignment as individuals move away from damaged areas. This dynamic migration creates challenges for providing necessary resources. Aid workers often find themselves relying on out of date population counts and maps, which are rendered obsolete in the face of mass population movements.

Description: With the rise mobile communications and powerful data processing systems initial efforts have been undertaken to evaluate the use of cellular communication patterns to plot and predict population movements in near real-time (¹–³), these studies have, through simulation, found an achievable predictive accuracy of around 88% (²); however, efforts to translate the theoretical findings into a working system suitable for deployment into a disaster situation are lacking. To address this need, we present Cascade, a unified analytics system designed to integrate call data records (CDRs), determine the geographic distribution of individuals within the affected areas, predict their future movement patterns, and present the findings in a user-friendly way that can facilitate decision making on aid distribution and allocation. The process begins with inputting CDRs, provided by the local telecom operators, into a dynamic Bayesian network (⁴), which is then used to make real-time predictions of incoming events streamed from the telecom network. This system allows for both robust machine learning training, and rapid analysis of emerging information and movement patterns.

Conclusion: By combining historical data and new events, and mapping them with an adaptive kernel density estimation (⁵), we can provide synthesized information suitable for use by emergency responders to better understand population dynamics and provide improved resource allocation.

The CDS Collaborative: Goals, Deliverables, and Future Directions

Salvador Rodriguez, PhD,1 Emory Fry, MD,2 Tadesse Sefer, MS,2 Phillip Warner, MS,1 Claude Nanjo, MAAS, MPH,2 Jerry Goodnough,2 David E Shields,1 Steven Elliott,2 Esteban Aliverti,2 Kensaku Kawamoto, MD, PhD, MHS1

1Department of Biomedical Informatics, University of Utah, Salt Lake City, UT
2Cognitive Medical Systems, San Diego, CA

Introduction

Standards-based clinical decision support (CDS) holds significant potential for enabling CDS at scale across institutions. To enable such standards-based CDS, several organizations have been focusing on the development and dissemination of open-source, standards-based CDS tools and resources, including the OpenCDS initiative (www.opencds.org), coordinated by the University of Utah, and the Socratic Grid initiative (www.socraticgrid.org), coordinated by Cognitive Medical Systems. The tools and infrastructure established by these groups are in use in a number of healthcare systems and electronic health record (EHR) systems. For example, Cognitive Medical Systems is currently leading the development of CDS capabilities in the next-generation EHR platform of the Veterans Health Administration using OpenCDS as a core component. To accelerate progress in this area, the CDS Collaborative was established to serve as a common home for organizations committed to open-source, standards-based CDS. Here, we describe the goals, deliverables, and future directions of the Collaborative.

Goals and Deliverables

The goal of the CDS Collaborative is to accelerate improvements in health and health care through the leveraging of open-source, standards-based CDS tools and resources. The deliverables of the Collaborative include the following:

Defined High-Value Use Cases. Given that the end goal for the Collaborative is to improve health and health care, the Collaborative has defined an initial set of high-value use cases needed by its current implementation partners. Further definition of use cases is ongoing based on the identified needs of members of the Collaborative.

Common, Standards-Based, Service-Oriented Architecture. Collaborative members are establishing a common software architecture based on the loose coupling of functionally independent Web services compliant with standard service interfaces, including the Health Level 7 (HL7) Decision Support Service, HL7 Common Terminology Services, HL7 Unified Communication Service, and HL7 Event Publication-Subscription Service standards.

Encapsulation of Software Components in Cloud-Ready Containers. Individual services and other components of the overall architecture are being encapsulated in Docker (www.docker.com) containers to enable cloud-ready deployment with minimal need for configuration. Services and components that have been encapsulated as of June 2015 include the OpenCDS Decision Support Service, several knowledge authoring environments (e.g., those based on the JBoss Guvnor and the JBoss KIE frameworks), and terminology management solutions leveraging the Unified Medical Language System and the Apelon Distributed Terminology System. These cloud-ready containers can be deployed on local servers as well if desired.

Sand-Box Environment with EHR Integration and Synthetic Data. In order to provide a productive and hands-on environment for the development and validation of CDS tools and resources, the CDS Collaborative is establishing sand-box environments complete with sample EHR systems (e.g., VA VistA and CPRS), CDS tooling, and sample CDS knowledge content. Synthetic data generation mechanisms are also being used to populate representative patient records. These sand-box environments are being deployed on virtual servers in a manner that can be replicated easily onto other servers.

Future Directions

Moving forward, the CDS Collaborative will be focused first and foremost on improving the scope, depth, and value of the tools and resources available through the collaborative. The Collaborative is also reaching out to interested collaborators who share in the Collaborative’s vision for improving care through open-source, standards-based CDS.

Conclusion

The CDS Collaborative provides a community, tools, and resources for the scalable deployment of open-source CDS solutions to improve health and health care.
A Case Study on the Effectiveness of an In-house Physician Rating Tool in Outpatient Clinics

Liu Ruijue1, Jiang Junhui, BEng1, Nadee Goonawardene, BSc1, Sharon S L. Tan, PhD1
1Department of Information Systems, National University of Singapore, Singapore

Introduction: To improve service quality and patient experience, healthcare institutions are placing increasing emphasis on providing patient-centered care, which ensures that patient value, preference and needs drive clinical decisions. Recent years have seen a surge in third-party healthcare rating websites as well as an emergence of in-house rating systems that aim to provide evaluations and feedback on clinics and physicians. While the effectiveness of myriad quality and outcome measurements has been studied, research on evaluating the effectiveness of rating tools in healthcare setting remains scant. The aim of this study is to evaluate the effectiveness of an in-house developed physician rating tool. In particular, we examine how patients’ perceptions and concerns about the rating tool affect their responses and how physicians’ perceptions and concerns affect their acceptance and use of the rating tool.

Methods: A multi-method study was conducted at a private medical center providing out-patient specialist services. This medical center uses an in-house developed clinical rating tool for customer experience monitoring and physician rating. The rating tool was designed based on a survey of various physicians rating tools and brainstorming sessions with the research team. After each visit, patients are invited to provide their feedback on an iPad which involves giving an overall recommendation score, and rating several dimensions including doctors’ listening, explaining, consultation time, as well as staff behavior, clinical environment, obtaining appointment, waiting time, and price performance. Qualitative analysis was based on interview data of patients and physicians which explored how they perceived and used the tool. Interviews were conducted in five clinics: 1) LASIK, 2) Eye, 3) Wellness, 4) Orthopedic, and 5) Obstetrics and Gynecology (OBG). From each clinic, 5 to 10 patients who have used the tool and 1 to 2 physicians being rated were randomly invited for a face-to-face interview. Each interview, which was audio-taped with the permission of the participant, lasted around 10-15 minutes and each participant was given a $10 grocery voucher. The interviews were then transcribed, coded and interpreted by researchers. Quantitative analyses involved conducting linear regression on archival rating data from the rating system. Results from both quantitative and qualitative analyses were triangulated to inform our findings.

Preliminary Results & Discussion: Our preliminary findings provide some interesting insights. First, based on quantitative analyses of the rating data, patients’ recommendation score for physicians is highly correlated with their physician’s explaining ($β=0.260$, $p<0.001$), listening ($β=0.162$, $p<0.001$), time spent ($β=0.114$, $p<0.001$), waiting time ($β=0.080$, $p<0.01$) and price performance ($β=0.078$, $p<0.01$). Based on qualitative analyses of interview data, patients were found to value different healthcare service dimensions. For example patients in OBG emphasized more on the interactions with physicians whereas patients in LASIK emphasized more on price performance and waiting time. Such differences were found to be rooted in two underlying factors: the outcome uncertainty of the treatment (i.e. experience-oriented – when medical outcome is more certain versus outcome-oriented – when medical outcome is less certain) and the time-horizon of the clinical interaction (i.e. short-term vs. long-term).

Second, majority of patients felt the rating tool was useful and were willing to participate. However, some concerns pertaining to three types of question sensitivities – threat of disclosure, question intrusiveness, and social desirability existed. For example, in terms of the “threat of disclosure”, patients who chose to be anonymous were found to give a lower average recommendation score to their physicians than patients who left their email addresses ($β=0.111$, $p<0.001$). Interview results also corroborated with this finding where some patients shared that they might artificially inflate their ratings if their identities were being disclosed for fear of affecting the relationship with their physicians.

Third, physicians were found to differ in their acceptance of the rating tool depending on their attributions of the ratings they received. Based on the interview data, physicians who attributed low ratings to unstable, internal or relational causes (e.g. lack of understanding or physician effort) were found to be receptive towards being rated by patients and as they felt that ratings could provide useful feedback for improvement. Physicians who attributed low ratings towards stable and external causes (e.g. patient incompetency rate or tool deficiency) expressed resistance toward being rated as they felt that low ratings were due to factors beyond their control.

Our findings provide useful implications on how to design an effective physician rating tool and increase patients’ participating and physicians’ acceptance.

Use of Diagnosis Related Groups to Predict All-Cause Pediatric Hospital Readmission Within 30 days

Victor M. Ruiz, MS¹, Amie J. Draper, BS¹, Ye Ye, MS¹, Andrew Urbach, MD², Fuchiang (Rich) Tsui, PhD¹

¹Real-time Outbreak and Disease Surveillance Laboratory, Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA
²Children’s Hospital of Pittsburgh of UPMC, Pittsburgh, PA

Abstract
This study assessed the contribution of diagnosis related groups (DRGs) in predicting all-cause pediatric 30-day readmissions. We used machine-learning techniques to identify predictive DRGs, and built a Bayesian classifier from a training dataset of 64,075 inpatient visits between 2007 and 2011. The model had an area under the ROC (AUROC) curve of 0.76 (95% CI 0.75-0.77). We believe that DRGs can be used to target post-discharge interventions aimed at reducing readmission rates.

Introduction
Unplanned 30-day hospital readmissions have been increasingly used as an indication of poor quality of care. Since 2012, the Centers for Medicare and Medicaid Services (CMS), under the Affordable Care Act, started penalizing hospitals with higher-than-expected rates of 30-day readmissions. These penalties caused hospitals to lose up to 1% of Medicare inpatient revenue in 2013.

Identifying patients at high risk of 30-day hospital readmissions is key for targeting costly care-transition or post-discharge interventions, aimed at lowering readmission rates. Unfortunately, predictive models have shown poor ability to identify 30-day all-cause readmissions.¹ In this study, we aim to assess the contribution of All Patient Refined (APR) and the CMS DRGs in predicting all-cause 30-day readmissions.

Methods
Data collection: We retrieved CMS-DRGs and APR-DRGs from inpatient visits to the Children’s Hospital of Pittsburgh of UPMC (CHP) between 2007 and 2013, excluding deaths during admission and visits missing DRG codes. Eligible visits comprised 13,645 readmission cases and 77,716 non-readmission controls.

Datasets: We used visits from 2007 to 2011 (9,547 cases and 54,528 controls) to train a naïve Bayes (NB) model, and visits from 2012 to 2013 to test its performance. A readmission-reduction program began at CHP in 2013; thus, we divided the testing data into two sets comprising visits from 2012 (2,119 readmissions and 11,676 controls), and 2013 (1,979 readmissions and 11,512 controls).

Modeling: We conducted a two-phase feature selection. First, we ranked features in the training dataset using the information gain score, which measures the reduction of uncertainty after observing an attribute. We discarded features with no discriminative ability. Second, we added features incrementally to a NB classifier in order of rank. At each step, we measured the 10-fold cross-validation AUROC after adding a feature to the current best model, and discarded those that did not increase the AUROC.

Results
The training dataset had 283 and 749 distinct APR-DRGs and CMS-DRGs, respectively. The best model included 14 APR-DRGs (along with their risk-of-mortality and severity-of-illness scores), and 7 CMS-DRGs. The model had an AUROC of 0.76 (95% CI 0.75-0.77) on both testing sets, and a Brier skill score (calibration metric) of 0.12.

Conclusion
We predicted pediatric 30-day hospital readmissions with high accuracy from DRGs. Although DRGs are available after discharge, they can be used to target post-discharge interventions aimed at reducing readmissions. Future work will include an assessment of the predictive power of data available before discharge, followed by a pilot at CHP to validate our prediction strategy in a production environment.

Representation of Genetic Variants in Genomic Sequencing Reports

Evelyn Rustia, MD1,2, Chunhua Weng, PhD2, Carol Friedman, PhD2
1 Division of Pediatric Hematology/Oncology/Stem Cell Transplant, Columbia University Medical Center, NY; 2 Department of Biomedical Informatics, Columbia University, NY.

Introduction In the past, the high cost, high labor, and slow turn around time had prevented genotyping to directly impact patients at the point of care. Although we are rapidly approaching the reality of a $1000 genome and seeing breakthroughs in technology that can return exome-sequencing results in a matter of days,1 there are still great challenges in incorporating this genomic information into daily practice. For instance, there are currently no standards for the reporting of genetic variants discovered from genomic sequencing in clinical documents returned to the provider. This results in an inconsistent reporting practice across institutions.2

Our research goal was to represent the elements that are routinely found in genomic reports at our institution.

Methods This is a retrospective study of 100 genomic sequencing reports in the electronic health record (EHR) for patients performed at NYP/Columbia University Medical Center, NY from 2013-2014. Examples of test types include “Whole Exome Sequencing (WES),” “Columbia Combined Genetic Panel (CCGP),” “Cancer Whole Exome Sequencing (CWES),” etc. The corpus content was manually analyzed and an information model was created to adequately cover concepts described in these reports. This study was approved by the Institutional Review Board at our institution.

Results Variant reporting is very complex and the summary of the finding often has a many components. We have created a model to represent how genetic variants are reported at our institution (figure 1). For example, the variant reporting contains the gene name in where the variant is found, a variant frequency (proportion of the abnormal copies of the variant among all the normal copies of the gene, reported as a percentage), and a modifier. The modifier generally indicates whether or not the variant has previously been reported in the literature.

Conclusions Our model represents the elements described when reporting genetic variants at our institution. These variants are crux of the reports; they are what most clinicians are looking to read. By creating this model, our goal was to attempt to standardize reporting within our institution and add to existing efforts to standardize genomic variant reporting in sequencing reports returned to clinicians. Our model includes some common elements3 as reported by other institutions however there still needs to be a universal consensus. Future work necessary includes collaboration with outside institutions to increase the generalizability of our model.

An Exploratory Analysis of Inpatient Satisfaction and Usage Pattern of Personalized Bedside Station

Borim Ryu, MS, Seok Kim, MS, Kee-Hyuck Lee, MD, MS, Hee Hwang, MD, Ph.D.
Soyoung Yoo, Ph.D

1Center for Medical Informatics, Seoul National University Bundang Hospital, Seongnam, South Korea

Abstract

The Smart Bedside Station (SBS) is a screen that is installed on the bedside for the personal use and provides a variety of convenient services for the patients. This study aims to identify information needs, satisfaction degree and current system use status of SBS at the tertiary general university hospital. We examined inpatient response by satisfaction survey and system log data of each patient. The experimental result indicates the system importance and inpatient satisfaction.

Introduction

With increasing technological development, mobile devices and related applications have been modernized, and high-performing bedside terminal devices with numerous features have been introduced for hospitalized patients. The design of such devices takes into account the device performance, quality of contents, and user-friendly structure and is based on the user experience. The main purpose of this research is to (a) explore the end-user satisfaction in hospital information systems and (b) derive patient information needs in order to improve SBS system. Preliminary results can be expected to support patient-centered healthcare service.

Methods

The SBS terminal OS was equipped with Android version 2.3 and integrated with Electronic Health Record (EHR) system. The SBS system provided patients with several services and we grouped these services into three representative menus; 1) My Menu that supports laboratory test, prescription explanation, operation, meal, admission/discharge and doctor round, 2) Information Support which consists of education contents, message checking, medical expenses and hospital guide, and 3) Convenience Service such as meal ordering, nutrition information, satisfaction survey and other convenient service ordering.

We conducted direct user interviews, patient online survey and log analysis of bedside terminal system for a year. A total of 1,860 patient survey and 11,240 user log data were explored in this study, from December 2013 to 2014. All experimental method has been done in hospital settings and with multiple users simultaneously.

Results

With the experimental data analyses, we could derive system usage patterns by month/year and functional needs from the patients in clinical setting. Survey respondent relationship with the patient, age, gender, education status and degree of familiar with the smart device were examined. Especially, education status and degree of familiar with the smart device were statistically significant with the overall satisfaction. Above many SBS services, Information Support was the most frequently used menu except entertainment (TV/Internet) that provide general health information, message notice, hospital bills inquiries and hospital guide information. The experimental results suggest that there are many opportunities to improve the efficiency of information delivery and task performance to reduce system complexity, improve service quality and improve user satisfaction.

Conclusion

Recently, bedside terminal systems have been increasingly adopted in hospitals due to the rapid growth of advanced technology in healthcare. Further study should be directed at developing sophisticated patient service with the potential aspects of information seeking and usage patterns.

Demographic Predictors for Completion of an Interactive Voice Response System Survey Coupled with a Real Time Transfer to a Pharmacist

Alejandra Salazar, PharmD1; Elissa V. Klinger, MS1; Jeffrey Medoff, BS1, Mary Amato, PharmD, MPH1,3; Patricia Dykes PhD1, Jennifer S. Haas, MD1; David W. Bates, MD, MSc1,2; Gordon Schiff, MD1,2

1 Division of General Internal Medicine and Primary Care, Brigham and Women’s Hospital, Boston, MA; 2 Harvard Medical School, Boston MA; 3 MCPHS University, Boston, MA

Introduction
In a previous study we demonstrated that an automated call-based pharmacovigilance system that integrates patient data from Electronic Health Records (EHRs) with an Interactive Voice Response System (IVRS) permitted primary care providers to identify drug related symptoms experienced by their patients (1). The purpose of this analysis is to study the demographic characteristics that predict a successful real time transfer to a pharmacist using an active pharmacovigilance system that incorporates data from the EHR into an IVRS.

Methods
A system was designed to collect patient demographics and medication related information from the EHR and upload them into an IVRS. Patients were invited to participate in an automated survey designed to screen for ADRs. At the end of the IVRS survey patients were transferred in real time to the study’s Clinical Pharmacist. The main demographic characteristics of interest for this analysis included age (18-30 years of age; 31-49 years; 50-74 years; and 75 years or older); sex; primary language (English or Spanish); and race as coded in the EHR (white, black, Hispanic/Latino).

Results
From the 11,945 eligible patients that were identified over 15 months, 5574 patients were randomized into the intervention. From that group, 4,847 patients received 5 to 10 IVRS call attempts and 3,301 patients (27.6%) answered the phone call. From those who successfully initiated the automated phone survey (609), 70.6% (n=430) patients were live transferred to the study pharmacist representing 13.03% of those contacted by the system.

Of the 430 patients who were transferred to the pharmacist to discuss their symptoms, 284 (66.04%) were female and 146 (33.95%) male (compared to 62% of females in the overall study population); 383 patients (89.07%) were English speaking and 41 (9.53%) Spanish-speaking. The racial distribution corresponded to: 45.12% White (n=194), 11.16% Black (n=48), 10% Hispanic, 1.16% Hispanic (n=5). Whites were most likely to finish the survey and progress to the real time transfer to the pharmacist (p=0.0079) compared to the other racial groups.

The age allocation of this cohort tallied: 59.77% (n=257 patients) were 50 to 74 years old, 22.09% (n=95) were 31-49, 11.16% (n=48) were 75 and older, and 6.98% (n=30) were 18 to 30 years old. In this category, the group most likely to be transferred to the study Clinical Pharmacist was the one corresponding to patients 50 to 74 years old (p=0.0095).

Discussion
We found that white race and age 50 to 74 were significant predictors of IVRS completion and real time transfer to the pharmacist for discussion of possible medication related problems. The highest overall rates of survey completion coupled with the live transfer were found for the group of English-speaking females in the aforementioned race and age category.

These results could have implications for the design and usability considerations of IVRS outreach calls in similar urban primary care settings.

This study was funded by grant # 5U19HS021094 from the Agency for Healthcare Research and Quality (AHRQ).

A Multi-Dimensional Consumer-Oriented Approach to Evaluate Patient Portals

Mandana Salimi, BS, Adriana Stanley, BS, Vickie Nguyen, MS, Sahiti Myneni, PhD, MSE
The University of Texas Health Science Center at Houston, School of Biomedical Informatics, Houston, TX, USA

Introduction
Patient portals are used to promote well-being and facilitate communications between patients and their providers. Although mobile technologies and health options are growing rapidly, patient portals are still not well used. We investigate how patient portal applications, both on mobile and web platforms, currently function from a behavior change technique, persuasive design principle, and usability perspective while taking into account various Gestalt principles, such as simplicity, that improves the quality of the interface.

Research Methods
Two patient portal applications were evaluated. The patient portal mobile app of a mid-sized medical facility was downloaded from the Google Play store. The web-based app was also accessed through a website log in page. The link to the apps and websites were provided by the staff of the medical facilities. Our evaluation of behavior change techniques was based on those developed by Abraham et al. To evaluate whether or not the patient portal apps had successfully adhered to persuasive design principles suggested by the persuasive systems design (PSD) model, we mapped the functions, features, and content of the patient portal applications to each persuasive design principle. Two health informatics graduate students separately evaluated these two patient portal applications according to the above principles. After completing the mapping of functions, features, and content of the applications to these factors, the evaluators assessed their reliability of agreement. The evaluators had a reliability of $k=0.65$, indicating fairly strong consistency and reliability in our evaluations. To evaluate these apps based on the persuasive design principles, we took each category and divided the total number of principles that each patient portal was positively marked for by the total number of principles suggested for that category. Similarly, we evaluated the patient portal applications based on their adherence to the fourteen heuristics of usability guidelines and on Gestalt principles – principles that describe different ways in which we tend to visually perceive individual elements into groups.

Discussion and Conclusion
Patient portal applications can help patients better manage their health and maintain healthy behaviors. As shown in Figure 1, we found that none of the patient portal applications employed behavior change techniques and have an overall low adherence, 46%, to persuasive design elements. However, on the positive side, we found patient portals had an overall high percentage of conformity, 90%, to usability guidelines.

Figure 1. The patient portal adherence based on our three evaluation principles.

Changing Physician Changeover: How adopting a tool in the EMR impacts the perception of paper handoff tools

Jonathan D. Salisbury MD, Indiana University School of Medicine and Emily C. Webber MD, Indiana University School of Medicine and Riley Hospital for Children at IU Health

Background
Resident physicians change over care of their patients frequently. Poor communication during these handoffs is the most common cause of serious safety events in the hospital setting. Standardized handoff tools have been shown to improve resident handoffs and improve patient safety. Electronic medical records (EMR) have been widely adopted and have been identified as one way to optimize physician changeover. Paper handoff tools and checklists generated from EMRs are still frequently utilized by physicians, but have not been widely studied. The objective of this study is to identify the impact of the EMR implementation of a consistent, standardized handoff tool on resident changeover.

Methods
The study period began in October 2014. Investigators identified champions for the handoff project and presented the project at multiple faculty forums. A previously validated handoff methodology was adopted which focused on standard use of fewer fields, clear expectations, and increased situational awareness (a ‘watcher’ status). Resident physician education regarding the change consisted of a resident conference along with electronic versions of the educational materials. The change in the structure of the EMR handoff tool (Fig 1, Fig 2) was built, validated and implemented in December 2014. Impact of the implementation was assessed in two methods during this study. First, in the month preceding and immediately after the intervention, EMR generated resident changeover sheets were collected and assessed for added information and deleted information (strikethroughs), in addition to other study endpoints. Second, residents were surveyed electronically to gauge their perceptions of physician handoffs prior to implementation of standardized changeover.

Results
The Wilcoxon rank-sum test was used to compare the distributions of the additions per patient and strikethroughs per patient in the pre- and post-implementation conditions. The count of additions per patient is significantly lower after implementation than before implementation (p = 0.035). The count of strikethroughs per patient is significantly lower after implementation than before implementation (p = 0.005). For our second method of analysis, nonparametric Wilcoxon rank-sum tests were again used to compare resident perception of changeover. Residents were found to be significantly more likely to believe that they have adequate information (p=0.018) and that they were prepared (p=0.019) in the post-implementation period compared to the pre-implementation period. The overall length of the paper changeover tool per patient did not change significantly nor did the amount of time residents changed over face to face.

Discussion
Analysis of resident use of EMR generated changeover tools after implementing a standardized method for handoff was found to significantly decrease the amount of additional information residents add or delete. We believe that the consistency of a standard handoff tool, as well as more limited, well delineated fields in the guide, helped improve the accuracy and completeness of both the verbal and paper changeover tools. At the conclusion of the study period, we identified ways to optimize resident physician changeover and improve patient safety in the hospital setting.

Figure 1. Pre-intervention sign off guide generated by EMR (5 fields for physicians to edit).

Figure 2. Post-intervention sign off guide generated by EMR (3 fields for physicians to edit, plus status and synthesis question).
MAC Annotator: An interactive tool for translating medication appropriateness criteria into structured form

Hojjat Salmasian, Carol Friedman, PhD

Department of Biomedical Informatics, Columbia University, New York, NY

Introduction

Inappropriate use of medications (IUM) is a global problem leading not only to excessive cost of care, but also putting patients at risk of avoidable harm. Traditionally, to identify IUM, clinicians use a set of guidelines, commonly referred to as Medication Appropriateness Criteria (MAC). Previously, we developed a framework for structured representation of MAC.1 To facilitate translation of MAC into structured form, we developed and validated a tool we call MAC Annotator, an interactive tool for annotation of MAC.

Methods

MAC Annotator is a client-side web-based program using the jQuery library. It allows the user to highlight a part of the narrative string, and to associate it with a concept in an existing biomedical terminology. It interacts with the NCBO Annotator application programming interface (API). It first uses the API to “pre-annotate” the MAC by identifying mentions of medication names and disease names using three terminologies (MeSH, RxNorm and SNOMED CT). It then allows users to add, modify or delete annotations, and facilitates this by providing a straightforward search mechanism for all terminologies available. We measured how many of the concepts could be automatically identified using the pre-annotation, how many could be found only by the user, and how many had to be defined manually (i.e. could not be found in any existing terminology). We also measured the time spent for each of these activities. To measure the agreement between annotators, we divided twice the number of concepts that were identically annotated by both raters to the total number of concepts identified by both annotators. This proportion can range between 0 to 100%, where higher numbers indicate more agreement between annotations.

Results

Six experts each annotated six MAC using MAC Annotator. The average time spent to complete the task was 121 seconds, of which 0.50 was spent for automated pre-annotation. Pre-annotation resulted in identification of 75 concepts, from which experts modified seven (9%) and accepted the remainder as correct. In the end, 180 concepts were annotated in the MACs, of which 107 referenced a concept in a terminology while the remainder were manually defined by the experts. The agreement between annotations was 77.3%. Agreement between annotators was 100% for medication names, and 100% for medication class names. With disease entities, agreement was only 50%. The main reason for disagreement was that annotators used different approaches when the disease was mentioned along with a modifier. For instance, one annotator broke down New York Heart Association Class III or IV heart failure to several concepts but the other used a manual definition for the entire term (in both cases, no terminology contained an equivalent term hence definitions were manual). Also, one reviewer provided a manual definition for the term uncomplicated pulmonary embolus while the other mapped pulmonary embolus to an existing terminology and provided an explanation for the term uncomplicated. The definition of certain terms was context-dependent. Examples include uncomplicated (as a modifier before a disease name) or monotherapy (which can be translated as “excluding other therapies for the same disease”), where the other therapies change for each disease. While some annotators provided context-specific definitions, others provided abstract definitions (e.g. defining uncomplicated as “with no complication”) that would be context-agnostic but not objective or computable.

Discussion

MAC Annotator facilitates the annotation of MAC through the pre-annotation step as well as through providing an easy to use, interactive interface for searching existing terminologies. It also helped identify content that is not well-defined in the original MAC, which can lead to different interpretations. Traditionally, annotation of biomedical text is done by a small number of expert annotators over extended periods of time.2 Previous work on creating structured versions of decision support rules also relies on manual annotation.3 MAC Annotator may help this process by speeding up the translation of these narratives into structured form. Pérez-Pérez et al have recently conducted a thorough review of public and well-known annotation tools. Compared to existing tools, MAC Annotator has the advantage of pre-annotating the text in a time-efficient manner with high accuracy, allowing annotators to define terms that are not explicit, and platform-agnostic design which doesn’t require any software installation by the user.

Integrative Informatics and Predictive Modeling Support for Population Health

Mary M. Saltz, MD, Joel H. Saltz, MD, PhD, Janos Hajagos, PhD, Andrew White, PhD, Charles Boicey, MS, RN-BC, Jim Murry BS, Ivan Crnosija, BA, Tahsin Kurc, PhD, Erich Bremer, MS, Jonas Almeida, PhD
Department of Biomedical Informatics Stony Brook School of Medicine, Stony Brook, NY

Introduction
This project targets development of proactive population health informatics methods in a geographically distributed medically and culturally heterogeneous population. The informatics infrastructure will be generally applicable to population health clinical informatics efforts, and is being developed in the context of the Center for Medicare and Medicaid (CMS) funded, 450,000 life (Medicaid and Uninsured), 3000+ organization New York Suffolk County DSRIP Performing Provider System (PPS). Future payments to the PPS will be directly tied to the overarching metrics of 25% reduction in potentially preventable hospitalizations (PPR) and emergency department visits(PPV) [3M Health Information Systems] and to improvements in patient quality indicators such as Agency for Healthcare Research and Quality (AHRQ) Prevention Quality Indicators (PQI) and Pediatric Quality Indicators (PDI) metrics. The complex interactions of each stand-alone project and the overall DSRIP metrics is such that changes to any part of this ecosystem will impact others. To this end, it is not enough to merely identify outcomes and trends, but also to design an in silico test bed to evaluate and thus steer proposed interventions or changes to the system.

Methods and Objectives
In order to plan, coordinate and steer population health activities, we need to assemble a 360 degree view that: 1) encompasses patient health, co-morbidities, geographic location; 2) takes into account each provider’s patient population, 3) is able to attribute PPRs, PPVs, PQIs and PDIs to health care systems and to providers. Creation of 360 degree health care views requires us to integrate multiple site electronic health records, New York State data from Statewide Planning and Research Cooperative System(SPARCS) and public health data including US Census Bureau, Behavioral Risk Factor Surveillance System(BRFSS) and American Community Survey data, along with data from deployed smart phones, mobile sensors such as Fitbits, Apple Watch and instrumented home medical devices.

Data integration pipelines, data quality control pipelines, data dictionary and data products are being created using a variety of tools, including a novel open source, streaming JavaScript based OpenHealth platform (https://github.com/mathbiol/openHealth). The tools are designed and configured to take secure advantage of a combination of open and protected data sources. Data products encompass clinical/computational phenotype generation - e.g. validated co-morbidities, treatment history and demographics. In the near future, data will also characterize patients by provider with respect to quality indicators such as PPRs and PPVs. Data will also include computed quality indicators, detailed insight into demographics using geo-located American Community Survey/Census data along with project specific data marts.

Success in the core DSRIP objectives of 25% reduction in PPRs and PPVs require systematic targeting of interventions and hence require coordinated population and risk stratification, as well as iterative adaptive analyses to allow on the fly interventions. Effective efforts to improve care transitions require projects to identify patients at risk and to characterize patients specific risks. This project will leverage a variety of machine learning methods including the techniques reported in [1] as data is collected as the DSRIP program is implemented.

Conclusion
While this project is still in its early stages, our tools and methods have already played a pivotal role in generating the detailed population health characterization that led to our near perfect Community Needs Assessment NY State DSRIP proposal score. The tools and methods developed have laid a foundation for predictive population health analytics planned over the 5 years of the project.

Predicting Acute Kidney Injury in Critically Ill Children Using Electronic Health Record Data – A Comparison of Four Statistical Learning Models

L. Nelson Sanchez-Pinto, MD1; Robinder G. Khemani, MD MsCI1. 1Pediatric Critical Care Medicine, Children’s Hospital Los Angeles, Los Angeles, CA

Background
Development or progression of acute kidney injury (AKI) is associated with increased mortality in the pediatric intensive care unit (ICU). Serum creatinine, the main AKI biomarker, is a late marker of the disease. Clinical prediction models can potentially identify high-risk patients earlier in their disease course. Our goal was to develop and compare four clinical prediction models of AKI in the pediatric ICU using electronic health record (EHR) data.

Design/Methods
We analyzed all patients 1 month to 21 years of age with no chronic kidney disease admitted to a single pediatric ICU between 3/2003 and 5/2012, who were in the ICU at least 24h. AKI was determined using the Kidney Disease Improving Global Outcome (KDIGO) criteria. Potential risk factors for AKI were analyzed using EHR data from the first 12 hours of ICU care and were compared between those with new or worsening AKI in the first 72 hours of ICU admission versus those with no AKI or no AKI progression. Risk factors were based on the pathophysiology of AKI with a specific emphasis on variables that are objectively recorded in the EHR and generalizable across pediatric ICUs. The dataset was randomly divided into training and validation sets (60/40 split of patients) and four statistical learning models were applied to the training data: logistic regression, classification tree, random forest, and support vector machine. Models were compared based on the area under the curve (AUC) of the ROC plot, sensitivity, specificity, positive and negative predictive value and likelihood ratios on the validation set.

Results
7029 patients met inclusion criteria, 6.3% (440 patients) developed new or worsening AKI within 72 hours of admission and these had higher mortality than those without AKI (28.9% vs. 3.5%, p<0.001). The original dataset contained 90 variables but was reduced to 8 variables for the final based on multivariate association with the outcome and the objective/generalizable criteria. The variables used were: age, lowest pH, lowest platelet count, highest blood urea nitrogen level, first serum creatinine level, highest bilirubin level, and whether the patient had a cardiac arrest or an operative procedure prior to the ICU admission. The performance of the four statistical learning models using these 8 variables is shown in Table 1. All models had the best performance with the same set of clinical variables. All models had a strong NPV and negative LR. Random Forest had the highest positive LR.

Table 1. Performance of the four statistical learning models in the validation set (n=2829, AKI+=179).

<td>0.81 (0.78-0.84)</td>
<td>0.79 (0.76-0.82)</td>
</tr>
</tbody>
</table>

PPV, positive predictive value; NPV, negative predictive value; LR, likelihood ratio.

Conclusions
We developed, validated and compared four objective clinical prediction models of AKI development and progression in the first 72 hours of ICU admission using variables that are easily extractable from EHRs and generalizable across pediatric ICUs. There were slight differences in performance between models, but they all had strong NPV and negative LR. Random forest had the best positive LR amongst the models. Clinical prediction models such as these can be used to develop clinical decision support tools to risk stratify patients, flag patients that could benefit from a urine AKI biomarker test, implement preventive bundles, or design clinical research studies.
Canary – a Graphic User Interface to a Heuristic NLP Engine

Nicolae L. Sandor, DM1, Stephen Skentzos, MA2, Alexander Turchin, MD, MS3,4
1Boston University, Boston, MA; 2Kanjoya, Inc, San Francisco, CA; 3Brigham and Women's Hospital, Boston, MA; 4Harvard Medical School, Boston, MA

Introduction
A large fraction of the Big Data in the EMR is difficult to analyze because of its narrative format. Narrative data can be studied using NLP techniques. However, many available NLP packages are either very costly or require that their users have substantial programming skills, limiting their adoption by mainstream clinical researchers.

We previously developed a versatile NLP engine that could implement both context-free and context-dependent grammar1 that was successfully used in large-scale analyses2. We have now developed Canary - a graphic user interface (GUI) to this engine that allows its use by individuals without access to software development resources.

Materials and Methods
The NLP engine that Canary uses allows the user to define a language model using the following components: a) word classes (ontology); b) phrase structures (grammar rules); c) order in which phrase structures are used; d) goal state(s); and e) output(s). It takes as input one or multiple text files. The engine is implemented in Perl. It supports multi-threading and hierarchical processing, attaining speeds of 40 documents/second.

Results
Canary implements a GUI for the NLP engine as a .NET based standalone Windows executable. Canary allows the user to enter / edit all of the language model components and apply the language model to a selected dataset to generate output over 11 dialog screens (See Figure 1 for an example). Canary interface assumes no knowledge of software development or NLP techniques. Canary executable and code are available upon request free of charge.

Meta-Analysis: Impact of Health Information Technology on Patient Engagement and Health Behavior Change

Suhila Sawesi, MS, PhD; Kanitha Phalakornkule, MS, PhD; Josette Jones, RN, PhD

\(^1\)IUPUI, Indianapolis, IN, USA

Abstract
This poster presents a meta-analysis of the impact of information technologies (IT) on patient engagement and behavior change. The primary goals of this review were to systematically determine, (1) impact of information technology (IT) platforms used to promote patients’ engagement and to effect in change health, (2) behavioral theories applied as bases for developing these interventions and their impact on health outcomes, (3) different ways of measuring health outcomes, (4) usability and acceptability of these technologies, (5) challenges and research directions for implementing IT platforms to meaningfully impact patient engagement and health outcomes.

Background
To reach optimal benefit from treatment, patients must engage in managing their health, not just simply following a physician’s recommendation.[1] Frequent, real-time communication and feedback are essential in supporting health behavior change and empowering patients’ engagement in the health care process. [2] However, the traditional model of care delivery, a face-to-face interaction with an expert and/or trusted health care provider, can be implemented only with a small number of patients and thus has limited impact. [2] In an effort to reach larger number of patients, researchers and clinicians have begun exploring the role of information technology (IT) platforms in patient engagement and health behavior change interventions.[2-3] IT interventions generally have potential benefits and some proven effects; however, specific components of the IT interventions associated with their success remain unclear. To better understand how to build successful IT interventions that can change patient behavior in a meaningful way, a meta-analysis was performed.

Method and result
PubMed, Web of Science, PsycINFO, and Google Scholar were searched for studies published between 2000-December 2014. Two reviewers assessed the quality of included papers and potentially relevant studies were retrieved and assessed for eligibility based on predetermined inclusion criteria. A total of 170 articles met the inclusion criteria and were reviewed in detail. Overall, 89% (151/170) of studies showed positive impact on patient behavior and 83% (141/170) reported high levels of improvement in patient engagement. Only 47% (80/170) referenced specific behavior theories and only 34% (57/170) assessed the usability of IT platforms. The majority of studies used indirect ways to measure health outcomes (66%, 112/170). Moreover, the follow-up assessments ranged from extremely short durations (1 week) to long-term ones (36 months), making it unclear as to how long the effects of these technologies would last. This review found no significant relationship between the studies that implemented the theory of behavior change and the impact of technology (P=0.97). Also, this review found no significant association between ways to measure health outcomes and the impact of technology (P=0.446). Lastly, the result showed significant association between usability and patients’ engagement in health care (P=.0216).

Conclusion
In general, the review has shown that IT platforms can enhance patients’ engagement and improve health outcomes. Few studies addressed usability of these interventions. Also, the reason of not using specific behavior theories remains unclear, and further research is needed to clarify these important questions. In addition, an assessment these types of interventions should be conducted based on a common framework using a large variety of measurements; these measurements should include those relating to motivation for health behavior change, longstanding adherence, expenditure, satisfaction, and health outcomes.

Automating risk score calculations and care recommendations by an EMR agnostic solution and potential time saving for providers

Marianne Scheitel; Hongfang Liu PhD; Jane L. Shellum; Ronald Hankey M.S. MBA; Steve Peters MD; Rajeev Chaudhry MBBS MPH
Mayo Clinic, Rochester, MN

Abstract

MayoExpertAdvisor (MEA) provides patient-specific risk score calculations and care recommendations using data from electronic medical records (EMRs). We report a timing study that evaluates the baseline cognitive effort and accuracy for the calculation of risk stratifications and recommendations for chronic heart failure (CHF), atrial fibrillation, and atherosclerotic cardiovascular disease (ASCVD). The study demonstrates that MEA can save time for providers in delivering automated risk score calculations and care recommendations with a great potential to improve compliance with recommended treatments.

Introduction

We developed MayoExpertAdvisor (MEA) to deliver care recommendations based on care process models (CPMs) established at Mayo Clinic based on national guidelines and expert consensus. MEA can calculate risk scores using data from electronic medical records (EMRs) with the goal of saving time and promoting consistency of care. The purpose of this study is to establish baseline data for efficiency and accuracy and to assess the potential for improvement.

Methods and Results

A fixed patient scenario was given to 22 primary care physicians, 4 residents, and 4 nurse practitioners. Each provider was asked to recommend treatment for CHF, atrial fibrillation, and hyperlipidemia and to calculate the associated risk scores (Seattle Heart Failure Model (SHFM)¹, CHA²DS²-VASc², and American College of Cardiology ASCVD risk respectively³). Each provider was recorded and analyzed with Morae ® (version 3.3.3) software⁴. The efficiency metrics collected includes the time and the number of clicks, keystrokes, and web page changes for each recommendation. The accuracy was determined by the number of providers that gave the correct risk scores and recommended care based on the corresponding CPMs.

The efficiency metrics are shown in Table 1. The CHA²DS²-VASc and ASCVD risk score were calculated with 90% accuracy. The capability of MEA calculating risk scores and recommending treatments automatically has the great potential to save significant time for providers and to improve accuracy of treatment.

Statistically Bolstered Opportunities Assessment in Measure Analytics

Elisabeth Lee Scheufele, MD, MS1, 2, Julianna Kohler, MHS1, Gerardo Soto-Campos, PhD1
1ConvergeHealth by Deloitte, Newton, MA; 2Harvard Medical School, Boston, MA

Abstract

We describe the use of the binomial test of proportions as a means to calculate the impact of patient level attributes on a quality or performance metric's population with a measure of statistical significance. Hospital administrators can use the output of this methodology as a statistically bolstered opportunities assessment and gain insight into potential detrimental or protective attributes of a metric's populations for investigation.

Introduction

Health care systems are actively working on multiple simultaneous performance and quality improvement initiatives. Typically, analysts monitor these activities via measures and metrics that calculate rates and averages and then focus operational efforts on those metrics that are performing outside of expectations. Investigating the metric's population for opportunities for improvement or for subgroups that demonstrate beneficial tendencies is often a particularly manual process. We introduce a methodology that allows statistically bolstered insight into patient attributes that may impact the metrics of interest to the health care system.

Methodology

We applied the binomial tests of proportions 1 to identify patients' descriptive attributes that may provide insight into possible beneficial or detrimental impact on measure scores. We apply this methodology to metrics numerically defined as a ratio with a denominator definition and a numerator that is defined as a subset of the denominator population. With this metric structure, the denominators of the two proportions are defined as the group of patients who make up the numerator (“meet the numerator definition”) and the group of patients who make up the remainder of the denominator (“not meet the numerator definition”). Then within these two proportion denominators, the proportion of patients with certain patient attributes of interest (e.g., “Caucasian”, “diabetes”, “18-44years - Age bucket”, “PCP: Dr. Smith”, etc.) are calculated. The binomial test of proportions is applied to the two proportions, producing a z score with a p-value. In Table 1, we demonstrate, with simulated values, the potential outcomes and interpretation of applying this methodology to a metric. In this example, the metric is one where maximizing the rate is optimal (e.g., “Rate of patients who have had influenza vaccinations”). It is necessary to make this distinction because it affects the applicability of the potential interpretation. In this case, the higher proportion in those who meet the measure could indicate a protective or beneficial attribute, while a higher proportion in those who do not meet the measure would indicate a possible detrimental or high risk attribute.

Table 1. Simulation of applying the binomial test of proportions on a maximizing metric

Conclusion

We have applied a statistical methodology to potentially streamline the work of identifying patient attributes that could be considered detrimental or protective to a measure of interest for a health care system. Primary limitation is that the binomial test of proportions is based on a z-score argument1, which assumes normality. Its applicability weakens as N becomes smaller. For the case of low N, we are considering bootstrap approaches2 to generate significance criteria.

Clinical Relevance of the Doctor’s Dilemma Question Set

Daniel R. Schlegel, Sashank Kaushik, Peter L. Elkin
Department of Biomedical Informatics, University at Buffalo, Buffalo, NY

Introduction

Every year at the annual ACP meeting, residents compete in the Doctor’s Dilemma (DD) competition [1] — essentially medical Jeopardy. The asked questions cover topics in all of medicine and range from simple trivia to complex diagnosis and treatment decision questions. Questions are split into 26 categories including topic areas such as History and Poisoning; and entire medical subfields such as Oncology and Cardiology.

Many computational systems attempt to answer clinical questions. For example, there are a great number of decision support tools which make use of patient data and answer a specific set of questions. There are fewer systems which attempt to answer all types of clinical questions, our eventual goal. In developing such a system, it is important to have a set of questions to train on. Such questions must be: topically diverse, covering many different topics and scenarios in medicine; and clinically relevant — questions should be those which could occur to a doctor during clinical practice. Questions may be those a doctor should know the answer to, or they may be ones normally looked up. Even a cursory glance shows that the DD questions cover many topics and scenarios, but it is unclear how many are clinically relevant — the subject of this study. Only the IBM Watson team has previously made use of these questions in developing a question answering system. They only used diagnosis questions, which are clearly clinically relevant [2].

Methodology

The DD question set was obtained through the ACP website and communication with the ACP. As of February 2015 it consists of 1110 questions. Of those, 171 refer to images and were excluded since we are only interested in textual questions. The remaining 939 questions were divided randomly into two datasets — with one to be used in later projects and not examined by our group during this study. From the remaining 465 questions in our dataset, we attempted to extract at least 10 questions from each of the 26 categories for manual review. This was not always possible since at least 10 questions were not available for each category. The result was a sample of 229 questions. Two clinicians, SK and PLE, examined and annotated each question as either clinically relevant, or not. The two annotators were in near–perfect agreement (κ = .87). The disagreements were mediated and a consensus was formed.

Results

Very little of the DD question set was found to be not clinically relevant — only 8 of the 229 questions (3.5%) in our sample. The primary category where irrelevant questions occur is History. Out of the 10 questions from that category, the annotators found that 5 were not relevant clinically. Other irrelevant questions came from the Ethics category (1 of 6 found irrelevant), Biostatistics (1 of 6), and Epidemiology (1 of 10).

Discussion

Once the results were tabulated, we analyzed the question categories which contained questions which were not clinically relevant in more detail. We found that the History section tends to contain a large amount of trivia. Questions such as “Nobel awardee for discovery of insulin” were labeled irrelevant since they aren’t helpful in clinical practice, while others such as “Previous name for reactive arthritis” may be relevant to a clinician, even though it is historic data. From examining the Ethics and Biostatistics categories, it was easy to see that they may contain non-clinical questions such as those about IRB approval and certain equation usage. It was surprising to see a question from Epidemiology in the irrelevant category, but the question: “Greek letter that represents the probability of making a type I error”, would probably have been better categorized as Biostatistics. Since the DD questions are mostly clinically relevant, we believe the set is a good tool for the development of clinical question answering systems.

Use of mHealth Technology for Supporting Symptom Management in Underserved Persons Living with HIV (PLWH)

Rebecca Schnall, PhD, RN¹, Haomiao Jia, PhD¹,², Susan Olender, MD⁴, Suzanne Bakken, PhD, RN¹,³
¹ School of Nursing ² Department of Biostatistics ³Department of Biomedical Informatics
⁴College of Physicians and Surgeons, Columbia University, New York, NY, USA

Abstract

The ability to self-manage adverse symptoms of HIV has been shown to improve patient-centered outcome in persons living with the disease. Mobile Health (mHealth) offers an ideal platform for the implementation and dissemination of evidence-based strategies for HIV symptom management. In our proposed work, we will develop a mHealth tool to provide real-time access to important symptom management strategies to improve patient-centered outcomes.

Introduction

HIV has evolved from an acute illness to a chronic illness¹ and patients, especially those with co-morbid conditions, have multiple adverse symptoms that require ongoing management. An individual's ability to self-manage the adverse symptoms of his/her HIV illness has been shown to improve patient-centered outcomes². In response to this need, a team at UCSF developed and demonstrated the efficacy of a paper-based symptom management manual with self-management strategies for common HIV/AIDS adverse symptoms³. However, subsequent use of these strategies has been very limited. To facilitate uptake, our study team developed and pilot tested a web-based system that delivers patient-centered tailored symptom management strategies for persons living with HIV (PLWH) to better manage adverse symptoms and improve overall quality of life⁴.

Approach

In our upcoming work, we will develop and evaluate the efficacy of incorporating symptom management strategies into a mobile health (mHealth) tool to improve symptom self-management for PLWH. Specific aims are to: 1) Apply participatory design methods to incorporate HIV symptom self-management strategies into a mHealth tool for use in patient self-management and 2) Using a randomized design, examine the effect of the mHealth tool as compared to a control group on primary outcomes of symptom frequency and intensity.

In this poster presentation, we will present findings from our participatory design sessions. Participants in our design sessions will include HIV patients and clinicians who will design the mHealth tool through user-centered design processes including use case. The resulting use cases will describe the behaviors of the user of the system and of the system itself and guide refinement of mHealth tool prior to usability testing.

Discussion

The ubiquitous nature of mobile technologies in daily life has created opportunities for health-related applications that were not previously possible. As such mHealth technology has the potential to be a highly valuable tool in the management of chronic illnesses such as HIV. Despite the growing use of mHealth technologies, many applications have not been rigorously evaluated and there remains limited evidence of their acceptability to intended users and impact on health care outcomes. Findings from this work may have broader implications for understanding if mHealth can improve efficiency and effectiveness of care for persons living with HIV.

Computerized Provider Order Entry Rates and Length of Stay Are Inversely Correlated

Richard Schreiber, MD, FACP1, Steven H. Shaha, PhD, DBA2
1Chief Medical Informatics Officer, Holy Spirit Hospital, Camp Hill, Pennsylvania—A Geisinger Affiliate; 2Professor, Center for Policy & Public Administration, Principal Outcomes Consultant, Allscripts

Intervention

This was a retrospective, correlational, interrupted time series analysis of CPOE rates and LOS measured over 30 consecutive quarters from July, 2007 through December, 2014. All patients and all orders were eligible except for medication orders in the ED which were not available electronically during the first part of the study from July, 2007 through December, 2012. During this interval there were 76,972 discharges and 6,135,994 eligible orders. All patients and all orders now including ED medications were reassessed similarly for the 8 quarters from January, 2013 through December, 2014, involving 25,795 discharges and 2,550,289 eligible orders. Case mix index (CMI) was tracked across all quarters. Statistical analyses included regression analysis, computation of Pearson’s correlation coefficients with arcsine, probit, and Fourier transformations, and calculation of R² coefficients and p values. Inflection point analysis was performed⁴.

Results

CPOE increases from 2008-2012 were significantly correlated with LOS reductions for 13 disciplines and organization-wide. Monthly CPOE-LOS data showed a linear, negatively-sloped relationship between CPOE and LOS (r = -0.798, p<0.001). The relationship was strongest as a sigmoidal curve (R² = 0.887, p<0.001). The inflection point⁴ where CPOE gained lasting favorable effects on LOS was at 60% adoption. Overall there was a 20.2% reduction in LOS attributable to CPOE. During 2013-2014 CPOE and LOS in seven disciplines that showed variation in CPOE rates exhibited converse, curvilinear trends precisely complementary to each other with R² of 0.76 and 0.73 respectively (p<0.001). Case mix index remained steady or rose from 2008 to 2012, and showed no change during 2013-2014 (t=0.036, p=0.81).

Conclusions

This study uses new methodology: it measured the impact of CPOE on LOS on a per-patient, per-visit, per-discipline basis thereby controlling for inherent differences in the rate of CPOE adoption by various providers. The authors believe this is a more accurate representation than overall summary statistics. This technique also helps to control for other efforts simultaneously undertaken to reduce LOS. This supports the hypothesis that CPOE contributes significantly to LOS, independently of the other numerous on-going efforts to reduce LOS.

The return on investment may not be apparent until CPOE rates exceed a tipping point. Attaining meaningful use stage 2 is necessary but not sufficient to realizing a return on investment of CPOE as measured by LOS.

Abstract: Drug allergy interaction (DAI) alerts are often overridden in the outpatient setting. We evaluated the rate of DAI overrides in the inpatient setting and why providers chose to override these alerts. The override rate of DAI alerts in inpatients was found to be very high (83.9%). The total number of alerts fired for true allergic reactions (immune-mediated) was only 38,224 (29%) of which 31,191 (81.6%) were overridden.

Introduction: Clinical Decision Support (CDS) systems can provide clinicians with relevant, treatment-related information and improve patient safety at the point of prescribing. Drug allergy interaction alerts (DAIs) are generated when a drug is prescribed to a patient that has a known adverse reaction. However, high DAI override rates have been reported in the outpatient setting.(1) We evaluated the DAI override rates in the inpatient setting and the reasons why providers chose to override these alerts.

Methods: All inpatient DAI alerts from Jan 2009 to Dec 2011 were obtained from the Brigham and Women’s Hospital, Boston, MA. These alerts suggest an undesirable interaction likely to injure the patient, and give the provider the option of either ‘cancelling’ the order or ‘overriding’ the alert. A total of 2,783 prescribers received allergy alerts at this site. The downloaded file included the name of the drug and allergen that triggered the DAI alert, and the reasons that the providers gave at the time of overriding the alert. Duplicates were removed and replaced, and patient information anonymized prior to analysis.

Results: The rate of DAI overrides was 83.9% (110,414 /131,615). Opioids triggered more than half of the alerts (50.9%, n= 66,949), with only 7,358 (10.9%) of these accepted by providers. The total number of alerts fired for true allergic reactions (immune-mediated) was only 38,224 (29%) of which 31,191 (81.6%) were overridden. Surprisingly, providers overrode 75.1% (4,917/6,546) of even alerts that indicated that the patient was at risk of developing anaphylaxis or angioedema. The most common coded reasons for overriding these particular DAI alerts were ‘Patient has taken previously without allergic reaction/patient has tolerated previously’ (55.5%, 2,730/6,546), ‘Physician aware’ (13.8%, n= 678) and ‘Low risk cross sensitivity, will monitor’ (11.8%, n= 582). Drug classes which were more frequently associated with allergies triggered 31,843 DAI alerts (24.2%); leading classes were cephalosporins (13.7%, n= 17,978), aspirin and NSAIDs (6.6%, n=8,730), penicillins (1.8%, n= 2,379), sulfonamides (1.4%, n= 1,819), ACE inhibitors and angiotensin receptor blockers (0.55%, n=724), contrast media (0.12%, n=161), and monoclonal antibodies (0.04%, n=52).

Conclusion: The override rate of DAI alerts in inpatients was found to be very high. This study offers important insights into the specific DAI alerts that were commonly overridden and the reasons given by providers. Of note, over 75% of the alerts that indicated that the patient was at risk of developing anaphylaxis or angioedema were overridden. The frequency of opiate-related alerts appears too high. Further research is needed to ascertain how accurate and relevant DAI alerts are for particular patients, and how to present the user with useful drug-allergy alerts.

Fine Phenotyping in lung Cancer Using Radiomics and Clinical Data

Luis E. Selva, Ph.D. 1, Saiju Pyarajan, Ph.D. 1,2
1VA Boston Healthcare System, Boston, MA, USA; 2Brigham and Women’s Hospital, Harvard Medical School, Boston, MA, USA

Abstract
In this abstract we present a novel approach for combining radiomic data extracted from routine clinical images with unstructured and structured clinical data for fine phenotyping.

Introduction
In routine clinical practice radiological imaging modalities like computed tomography (CT) are mainly used either to detect/confirm tumor or to measure changes in tumor size in response to treatment. Recent advances in image processing methods allows for the extraction of numerous quantitative features from clinical images. Aerts et.al (1) recently showed effectiveness of radiomics data as a classifier in both lung and head-and-neck cancer. We used a similar method to couple quantitative features extracted from routine clinical images with structured data derived from pathology and radiology notes using advanced natural language processing (NLP) techniques to attempt to further define clinical phenotypes or sub-phenotypes which could potentially be used as signatures for prognostic prediction.

Conclusion
CT scan images from Non-small cell lung cancer patients were used to extract a number of quantitative features. Structured data were also extracted from Clinical notes. Clustering methods were then used to classify the radiomic and clinical phenotypes. The groups were then compared for differences in tumor progression and response to treatment.

Cluster Analysis Algorithm For Cohort Comparison

Sunny Shahdadpuri, MBBS, MBA¹, Aditya Sane, MS, BEng¹, Purav Gandhi, MBBS, MBA¹
¹ConvergeHealth by Deloitte, Newton, MA

Abstract
Clinical research on real-world dataset involves a large multitude of clinical data parameters including demographics, diagnosis, surgeries, procedures, prescriptions, laboratory variables as well as side-effects and adverse events. We have developed an advanced visualization to perform a cluster analysis to study relationships between these various data parameters, to create virtually all possible sub-cohort combinations and identify the ones that have significant difference in outcomes.

The Challenge
The explosion of data generated by increasing adoption of electronic medical record (EMR) systems in the last decade enabled by both technology and regulation has created immense opportunities for researchers. Life science researchers are analyzing large volumes of data across various categories like diagnosis, treatments, procedures, prescriptions, and therapeutic pathways. With a large number of data element categories, it is difficult to understand which data attributes drive differences in key outcomes. There is an impending need to be able to rapidly elucidate these drivers and identify the corresponding patient populations, so that medicine delivery could be more precise and targeted.

Method
We have developed a system for analysis and visualization of multitude of clinical variables in context of a clinical study. This system allows for prioritization of variables based on importance, assessment of impact of these variables, and their relationships on end outcomes and quantification of the impact using industry standard comparison tests. There is also a provision for iterating on the results by selecting different cohorts for analysis. The steps followed in our system of analysis are as follows:

- Selection of cohorts and outcomes based on the disease areas and study objectives
- Determination of a top list of attributes ranked according to statistical relevance using the Maximal Information Coefficient (MIC)²
- Cluster formation based on different combination presence or absence of up to twenty clinical variables for the selected cohorts of patients³
- Tracking of each of the clusters for the selected outcome and assessment of statistical difference between the outcomes values for the two cohorts. Statistical difference can be interpreted through a multitude of tests including mean variance, odd ratios, log-odds, or Yule’s Q.

Results
As a result of the above four step process, we have a robust system for cluster analysis to deal with the multitude of clinical variables for each patient, which helps with:

1. Identifying the most relevant clinical parameters for any clinical study
2. Analyze the impact of these parameters as well as their relationships on the outcomes for cohorts of interest
3. Measure statistical significance of the comparison
4. Repeat steps 1 to 3 for a different set of cohorts in a real-time analysis

Discussion
With this concrete approach for comparative statistical analysis based on clustering in mind, we are trying to broaden the applicability of the cluster analysis framework to longitudinal analysis as well as to data sources like claims. We are also in the process of bringing in other statistical tests and modeling techniques as a supplement to the cluster analysis.

A Framework for Assessing Clinical Data Suitability for Observational Study

Ning Shang, PhD, Chunhua Weng, PhD, George Hripcsak, MD, MS
Department of Biomedical Informatics, Columbia University, New York, NY, USA

Introduction
With the growing availability of electronic health record (EHR), more and more researchers are starting to use clinical data in EHRs for observational studies. The lack of precise characterization of clinical databases and well-accepted measures of their suitability for observational studies is one of the major barriers to sharing such data for facilitating Big Science. This study aims to develop a framework for characterizing clinical databases and evaluating their suitability for observational studies. It was developed through a literature review that identified common data needs in clinical databases for observational studies by clinical researchers, and frequent designs of clinical databases for research reuse.

Methods
We surveyed the literature on two topics: one on population-based observational studies using clinical databases and the characteristics of these databases that are pertinent to researchers and the other on desiderata (desired characteristics) of clinical databases for understanding the challenges facing research reuse of clinical databases. Fifty-three relevant full-text articles were selected from the 228 retrieved from the search and reviewed for author characterizations of data sources and frequent data limitations, and database design challenges for research reuse. By combining the two review topics derived sub-measure sets, and grouping them into different measures, a conceptual framework was developed to capture the aspects that should be considered for choosing appropriate clinical databases for conducting observational studies.

Results
We identified 21 sub-measures from observational studies utilizing a clinical database, and 35 from desiderata studies. Eighteen of those are shared from both study groupings. A total of 38 sub-measures were grouped into 16 measures that are conceptualized as five categories: policy and administration, relevancy, descriptive metadata and provenance documentation, usable, quality (Table 1).

</tr>
</tbody>
</table>

Conclusion and Discussion
A suitability framework was developed to assess the appropriateness of clinical databases for observational studies. The framework enumerates all the factors that a researcher might want to consider in searching for and selecting a clinical database to use in their research. This framework was built with the perspectives of data custodians and data consumers in mind. For evaluation, we will perform a national survey to validate the framework and elicit experts’ opinions on important metrics. To implement the prototype of the framework, we plan to extend the OHDSI ACHILLES (Automated Characterization of Health Information at Large-scale Longitudinal Evidence Systems) tool to offer potential database users the ability to interactively review the databases for their research.

Drug Database Refinement Using Machine Learning and Text Analysis

Reza Sharifi Sedeh, PhD¹, Xianshu Zhu, PhD¹, Yugang Jia, PhD¹, Joey Liu, BSc¹, Oladimeji Farri, MBBS, PhD¹, Daniel Elgort, PhD¹
¹Philips Research North America

Abstract
One of the main challenges in utilizing Healthcare databases is the existing non-uniformity across the databases. We implemented an NLP- and machine learning-based approach to standardizing and mapping drug names to corresponding HICL codes. We applied a Naïve Bayes method to the intensive care unit (ICU) medication database of Philips eRI database, which is pre-processed and cleaned with a natural language processing (NLP) pipeline. Following our evaluation on a sample data set, we have achieved 99.7% of accuracy in predicting correct, uniform drug name entries.

Introduction
Naïve Bayes [1] is a popular and widely used machine learning approach for text classification. However, when there are errors (e.g. misspellings) and redundancies within text data, the performance of machine learning techniques (including Naïve Bayes) can dramatically decline. We hypothesize that machine learning techniques in combination with NLP, as a preprocessing task, would greatly improve the performance of algorithms to accurately classify text for the purpose of refining and standardizing large and 'messy' medication databases for effective down-stream use in clinical and pharmaceutical research.

Methods and Results
We implemented an NLP- and Naïve Bayes-based approach to standardize the Philips eICU Research Institute (eRI) medication database, comprising therapy information over two million patients in over 350 US Hospitals with large amounts of data entry errors and redundancies, and map the drug names to corresponding HICL (Hierarchical Ingredient Code List) codes. Using the Philips proprietary NLP infrastructure which references several ontologies and a home-grown pharmaceutical abbreviation database, we carried out the NLP-based drug name cleaning via four steps: removal of doses and units from the drug names using regular expressions (e.g. 20mmol KCL = KCL), replacing the non-standard abbreviations with full-length drug names (e.g. Fent = Fentanyl), correction of misspellings by referencing a Lucene-based spell-check dictionary of n-gram indexed terms from SNOMED CT, RxNorm, NDDF and general English vocabulary (e.g. Dilauded = Dilaudid = Hydromorphone), standardizing the drug names by including appropriate white spaces (e.g. Calcium gluconate = Calcium gluconate) and removing non-distinguishing keywords (e.g. Propofol volume = Propofol).

The 'cleaned' data resulting from the NLP pipeline becomes the training set for a Naïve Bayesian estimator which uses the corrected (pre-processed) drug-names and their corresponding class indices, HICL sequence numbers, which are a universal and standardized nomenclature for medications and their ingredients. During the training process on a training set of over 68 million drug entries and their corresponding HICL sequence numbers, two important parameters are calculated: (i) the percentage frequency of a drug name appearing within a given HICL class and (ii) the percentage frequency of a specific class (HICL sequence number) appearing in the whole sample. These two parameters are used later during the testing phase, where the probability of a given drug name belonging to a HICL class is calculated. As a result, given the drug name, the class that has the highest posterior probability is selected. One of the authors (OF) with clinical and pharmacological expertise manually reviewed the performance of our approach on the most frequent entries (~93%) of a table of over 57 million drug entries, which is comprised of 89.5% drug name entries and 10.5% non-drug name entries. Our approach is 99.7% accurate in predicting correct, standardized drug name entries (Table 1). It is also noteworthy that our approach was only targeted at standardizing the drug name entries, and not the non-drug name entries such as Normal Saline and Packed Red Blood Cells.

Table 1. Manual evaluation of our proposed approach on a sample data set.

Registries in Accountable Care: Essential Data Management in New Models of Care

John Sharp, MSSA\textsuperscript{1,2}

\textsuperscript{1}HIMSS, Cleveland, Ohio; \textsuperscript{2}Kent State University, Kent, Ohio

Abstract

Registries are a powerful informatics tool for research and public health. As both commercial payers and the Centers for Medicare and Medicaid Services work to shift incentives toward value-based purchasing, demand for reliable, accessible data on populations is growing. The purpose of this poster is to define accountable care organizations (ACOs), explain the importance of registries in managing data for ACOs, and discuss specific informatics requirements unique to accountable care registries.

Introduction

Registries have traditionally been used for research to study conditions and treatment groups, public health to monitor disease and epidemics and quality registries for public reporting.\textsuperscript{1} Registries for accountable care have some similarities to these registries but a different focus and incentives: to manage a population based on an insured cohort and incentivized by risk-sharing insurance plans. Quality reporting is a requirement for risk-based contracts as such, quality measures are key data points.\textsuperscript{2} These registries also require risk-stratification methods to facilitate care coordination.

Designing ACO Registries

As with any registry, the purpose and objectives must be designed at the onset. Patient cohorts are typically defined by the risk contract from Medicare or insurer. Data elements need to include data that enables risk-stratification and quality reporting.\textsuperscript{1} Sources of data include electronic medical records, insurance claims and patient questionnaires. Data architecture must be flexible as needs within the new care model can change quickly. Data integration from these sources continues to be a challenge especially for patient matching, data migration and entity disambiguation.

Transforming Registry Data in Knowledge

To make the data actionable for clinical decision support and care coordination, dashboards and data visualization tools are essential. Self-service analytics for all members of the care team assist in identifying new risk factors and subgroups that require intervention. The next level of transforming this data is predictive modeling; this is especially important in predicting risks in chronically ill populations, which may result in unnecessary emergency room visits or hospitalizations. Informatics tools, such as, integrated decision support based on these models, can improve care.

Future Role for Use of Registries in Accountable Care

In the dynamic nature of accountable care, structure and data needs are constantly changing. New approaches to obtain and analyze data near real-time are challenges for these registries. Quality metrics can vary from one payer contract to the next. Standardization of these metrics will enable more efficient use of registries in the future. Currently a centralized repository of best practices is lacking and would be helpful as ACOs expand nationally. Innovation should be encouraged to solve these and other issues as they arise.

Conclusion

Registries for ACOs are a key informatics tool for the success of this care model. While there are similarities to other types of registries, accountable care registries have unique requirements including near real-time data, specific quality measures, support for care coordination and risk stratification.

MedBus: A service-oriented architecture for enabling the research data economy

Amitava Shee, BE¹, James Estill, PhD¹, John Brussolo, MBA¹
¹University of Michigan Medical School Information Services, Ann Arbor, MI, USA

Abstract

Researchers often require access to multiple data repositories to carry out their work. Although these data sources are a valuable asset to the community, researchers are often left to find these resources and navigate access to these data on an individual, point-to-point basis. In order to accelerate data discovery and access we developed a service-oriented architecture platform, MedBus, for securely self-provisioning these resources. MedBus will ultimately enable federated access to over 300 enterprise data repositories.

Problem

Modern research programs often require integration of high velocity data from heterogeneous sources within a variety of analytical platforms. Researchers at our institution utilize data from over 300 enterprise repositories and are required to integrate these resources on an individual point-to-point basis. Furthermore, discovery of these data repositories can be difficult, and the process of how to negotiate access to these resources can be opaque. Although centralized data warehousing in platforms such as i2b2 can facilitate data access and interoperability, there also exists a need for data federation systems that can respond to the dynamic requirements of big data and enable use cases that require integration independent of any single platform.

Solution

To address the needs for a secure, federated solution supporting research, we developed MedBus (http://goo.gl/1Bg4rc), a service-oriented architecture (SOA) that addresses the current and emerging challenges of research data discovery, access, and integration. The MedBus enterprise service bus presents research data as a collection of interoperable data services that are agnostic to the technology in the underlying data repositories. These services facilitate user-oriented mashups of research data and provide an extensible platform for increasing the visibility and utility of enterprise data resources. Since MedBus has been built from open source components, individual data owners can develop services that provision data within the MedBus framework, and the broader research community can be engaged in the extension of the MedBus platform.

Results and Conclusions

The initial deployment of MedBus includes services that provision data from: 1) a physiological waveform metadata store (5GB) and 2) the laboratory information management system (LIMS) used by our institutional biorepository (currently 148K specimens from 25K subjects). These services are consumed by a locally developed cohort discovery and data delivery tool that provides a secure and intuitive interface for complex queries that connect data from these services with patient data from our institutional EHR warehouse. This has resulted in accelerated access to research data in a self-service environment that facilitates the transition from structured data to actionable information. Current MedBus development includes the addition of a data access attestation service and eConsent that integrates with IRB approval workflows. We are also incorporating data virtualization as a method to accelerate development of new data services.
Data Mining to Predict Healthcare Utilization in Managed Care Patients
Lincoln Sheets, MD1,2, Michael A. Phinney, BS3, Sean A. Lander, MS1,
Jerry C. Parker, PhD2, Chi-Ren Shyu, PhD1,3,4
1University of Missouri, MU Informatics Institute, Columbia, Missouri
2University of Missouri, School of Medicine, Columbia, Missouri
3University of Missouri, Computer Science Dept., Columbia, Missouri
4University of Missouri, Electrical and Computer Engineering Dept., Columbia, Missouri

Problem Addressed. Predictive analytics can be used to rapidly spot hard-to-identify opportunities to better manage care1, but most current risk prediction models fail to reach 80% accuracy2, but data mining algorithms would permit models that surpass the size limits of traditional statistical methods3, and could use the rich data available in the EHR4.

Methodology. From a sample of 10,000 primary care patients, those with the highest charges during one year were compared to an equal number of patients with the lowest non-zero charges. Clinical attributes were associated using the FP Growth algorithm, and validated by multiple regression.

Results. Of 19,012 EHR data elements, 9 predicted charges over $75,000 (p<0.20).

| EHR Code | Description | Pr > |t| |
|----------|-------------|------|---|
| 786.6    | Swelling, mass, or lump in chest | 0.0368 |
| V72.84   | Pre-operative examination, unspecified | <0.0001 |

| --- ICD-9 Diagnostic Codes --- |

| --- Diagnosis-Related Groups (DRG) --- |

| 358 | Digestive system procedures without complicating conditions | 0.0524 |
| 571 | Skin debridement with complicating conditions | 0.0242 |
| 640 | Disorders of fluids or electrolytes with major complicating conditions | 0.0015 |

| --- SNOMED Codes --- |

| 493070016 | Ischemic heart disease | 0.0052 |

| --- Therapeutic classes of prescriptions --- |

| 5-HT3 antagonists | <0.0001 |
| CD20 monoclonal antibodies | 0.1026 |

| --- Other clinical attributes --- |

| Body Mass Index (BMI) < 18.5 | 0.0044 |

Conclusions. Systematic mining of clinical attributes from the electronic health records of adult primary care patients reveals multiple predictors of high healthcare utilization. Association mining narrows feature sets that are otherwise too large for linear regression, with good resulting overall significance.

A Continuous Markov Model Approach Using Individual Patient Data to Estimate Mean Sojourn Time of Lung Cancer

Shiwen Shen\textsuperscript{1,2}, Simon X. Han\textsuperscript{1,2}, Panayiotis Petousis\textsuperscript{1,2}, Frank Meng\textsuperscript{2} PhD, William Hsu\textsuperscript{2} PhD, Alex A.T. Bui\textsuperscript{2} PhD

\textsuperscript{1}Department of Bioengineering, \textsuperscript{2}Medical Imaging Informatics (MII) Group, Department of Radiological Sciences; University of California, Los Angeles, CA, USA

\textbf{Introduction.} Large amounts of existing periodic screening data for chronic diseases offer the potential in to better understand disease dynamics and progression. This knowledge is able to provide individualized recommendations for screening and diagnostic tests. One major challenge of leveraging this data is that there are large amounts of missing or partial observations. For instance, patients found to have lung cancer might receive treatment/intervention, thereby obviating further observations on lung cancer progression. To overcome this problem, we present an approach based on the continuous-time Markov model (CMM) and apply it to estimate lung cancer progression, specifically the average duration time in the preclinical screening detectable state before progressing to the clinical symptomatic state. This duration is also known as the \textit{mean sojourn time} (MST) and provides an absolute upper limit to the obtainable lead time. MSTs can vary significantly across screening approaches, reflecting the efficacy of the screening process. Low-dose computed tomography (LDCT) and chest x-ray (CXR) are two important modalities for lung cancer screening. The National Lung Screening Trial (NLST) was a randomized multicenter study that compared these two imaging modalities’ ability to detect lung cancer in an at-risk population (older current and former heavy smokers). In this work, we use the NLST dataset to estimate MSTs for LDCT and CXR. Our approach assumes the individual resides in one of the predefined states and can capture continuous time information between states. This work describes the first time that a CMM-based approach is applied to estimating MSTs for lung cancer under LDCT and CXR using individual-specific transition time information for a large population dataset.

\textbf{Methods.} We develop a three-state homogeneous continuous Markov model for the LDCT screening arm. For LDCT, the three states are respectively defined as: State 1, no detectable cancer; State 2, preclinical cancer; and State 3, clinical cancer. Individuals can only transition from State 1 to State 2, and from State 2 to State 3 (as shown in Figure 1). The transition rate from the non-detectable state to the preclinical state is $\lambda_{1,2,LDCT}$, and similarly the transition rate from the preclinical to the clinical state is $\lambda_{2,3,LDCT}$, where $1/\lambda_{2,3,LDCT}$ is the MST. Based on the transition rates a matrix is formulated comprising finite transition probabilities $P(t)$. Each element of this matrix represents the transition probability of an individual case across the states of the Markov model. NLST participants underwent three rounds of screening. For each round of the screening, screen-detected lung cancers are assumed to be at the preclinical state, and negative cases are assumed to be at State 1. Interval cancer cases are assumed to be at the clinical state. The transition time between states for each individual is accounted for in this model (24,988 subjects in CXR arm and 25,473 subjects in CT arm). Post-screening reported cancers are not included in this study. We initially assume that the sensitivity of each screening is 100%. Maximum likelihood estimation (MLE) is used to estimate the parameters and solved using a quasi-Newtonian optimization method. The MST for specific patient cohorts is estimated by using a proportional hazards model to relate the transition intensities to covariates (e.g., gender). A similar approach was used to develop the model for the CXR arm.

\textbf{Results.} Our estimated MSTs are: 0.7 years (95% confidence interval: 0.61-0.83) for CXR and 1.76 years (1.58-2) for LDCT. For LDCT, the female and male MSTs are 1.94 years (1.10-3.69) and 1.64 years (1.10-2.62); the CXR MSTs are 0.67 years (0.41-1.15) and 0.82 years (0.58-1.22). Our estimations are comparable to reported MSTs for lung cancer in recent studies (1.33-6.08 years for CT and 0.45-2.24 years for CXR).

\textbf{Conclusion.} In this work we estimate a longer MST for patients who underwent LDCT screening compared to CXR in individuals at high risk, suggesting that LDCT is more effective in detecting early stage lung cancer. The CXR MST is less than 1 year, suggesting a smaller window of opportunity for lung cancer screening. There is no significant difference between MSTs of females and males in both LDCT and CXR.

Identifying population characteristics tables in full text articles
Garrick Sherman, MS, Catherine Blake, PhD, Jooho Lee, MS
University of Illinois, Urbana Champaign, IL, USA

Abstract: Authors frequently use tables to provide population characteristics of patients who participate in a study. Automated indexing methods tend to focus on the narrative in an article, rather than tables, even though this data can help physicians determine whether a study is relevant to their current clinical encounters. We provide an automated method to identify tables that contain population characteristics, which can be extracted in a later step.

Introduction
Several efforts have focused on standardizing the data reported in a clinical trial (CONSORT), a meta-analysis of observational studies (MOOSE), and an epidemiological study (STROBE). These new guidelines do not address how to extract information from the millions of already published studies. Our goal is to identify and extract demographics (e.g. age, gender, and ethnicity), behavioral factors (e.g. tobacco and alcohol consumption), and medical descriptors (e.g. disease stage) from tables, such as that shown in Figure 1. As a first step, we identify tables containing data corresponding to the patient aspect in PICO [1] and population, intervention or risk factor, and medical condition of the information synthesis framework [2].

Materials and Methods
Full text articles in 18 breast cancer journals from the open access subset of PubMed Central were downloaded. Tables were extracted from the 3,638 NXML files; only the first table is included in these experiments. A heuristic approach to processing tables, similar to [3], was used. Headers were identified using HTML tags, and factors were defined as the first non-empty cell in a row that included either a) only one non-empty cell, or b) at most half as many non-empty cells as total cells in the row (including empty cells). Once factors were identified, the first cell of the next row was interpreted as a level and all subsequent cells in that row were considered values. Differently structured tables were labeled with a generic “Main” factor, but otherwise parsed identically.

The task of identifying population characteristic tables was framed as a classification problem. Several features were considered: factor unigrams, factor and level unigrams, caption unigrams, and numbers. Only unigrams were considered due to the brevity of table text. Text was tokenized on whitespace and converted to lower case (no stemming was applied since terms were not expected to exhibit many forms). Stopwords were eliminated, as were terms occurring in ≤3 or >95% of the tables. A training set of 1,001 tables was annotated by hand (414 population tables), and information gain (see [4]) was used to identify the most discriminating terms. Four classifiers—support vector machine (SVM), naïve Bayes (NB), decision tree (DT), and the general linear model (GLM)—were used to classify the test set in the Oracle Data Miner (with default settings). The features identified in the training set were then used on an unseen test set comprising 497 tables.

Results
NB outperformed the other classifiers for all feature combinations, with a maximum accuracy of 87.6% on the judged subset, which included 50 random positive and 50 random negative examples. The most effective set of features were the top 50 terms, no captions or numbers and two columns (i.e. using terms from both the factor and levels). The NB model was applied to the test set. There were 29 false positives and 32 false negatives leading to an overall accuracy of 87.73% in the test set.

Performance Comparison of Running Clinical Rules in Drools and Plain Java Implementation

Jian Shi, MD, MS, Erik Smith, Thomas J. Van Gilder, MD, JD, MPH
Transcend Insights, San Diego, CA

Introduction

Drools is an open source, Apache Foundation, community-based project that provides an integration platform for the development of knowledge-based systems. It is developed in Java and has a modular architecture which is based on an object oriented implementation of the PHREAK – a lazy rule matching algorithm to enable Drools to handle a larger number of rules and facts. Drools has the following major advantages: Declarative Programming, Logic and Data Separation, Speed and Scalability, Centralization of Knowledge and Understandable Rules. It can also be easily integrated with other open source frameworks such as Spring and Apache Camel, among others. Because of those advantages, Drools has been used in healthcare systems to process clinical rules. It is the core component of OpenCDS which has numerous collaborators like Intermountain Healthcare, Wolters Kluwer Health and others. Compared to rules in other industries, clinical rules tend to have more complicated logic, especially to implement healthcare quality measures. No study has been found regarding the performance of Drools to process clinical rules.

Methods

Drools version 6 was installed and two other services were implemented to feed the patient data and value set codes to the Drools rule engine. The childhood immunization measure (10 different vaccines) from HEDIS was then written in Drools. The eligibility was written in one rule, and the compliance and optional exclusion for each vaccine were written in separate rules. The same rule logic was also hard coded directly in Java. The rules were grouped by each vaccine. The run time was then measured against the number of vaccines that were analyzed on each run. The plain Java implementation shares the same architecture except that the engine component is implemented in plain Java, and reuses the patient data and value set services. Both implementations were run against the same 10,000 patient claims database with about 300,000 records. The output was then compared.

Results

There is a learning curve to implement Drools and writing rules in Drools rule language (drl). The age requirement can be easily done while continuous coverage, value set matching and counting unique service dates that are slightly challenging due to the limitation of the operator/functions packaged in Drools. This requires Java coding either in utility class or the rule “then” section. When comparing the results, two different implementations generate the same output. The data loading which was implemented in JDBC takes a significant portion of overall run time. The comparison of performance was done with the exclusion of data loading time. The results are shown below.

Conclusion

Simple requirements like age range or a look back window can be easily implemented in the drl file. Any update to those requirements can be done within the rule grammar without making any changes to the engine coding. The rule execution time on clinical rules with certain complexity is impressive, yet it is still longer than the plain Java implementation. For a use case in which continuous updates occur, Drools is a good option to consider. However, if performance (as measured by execution time) is the main metric, it may be worth researching other implementation options.
Implementation of a Mobile Electronic Medical Record System that Uses a Problem-oriented Contiguous Timeline View

Akiko Shibuya, RN, PHN, PhD1, Keisuke Ogawa, MS2, Kazunori Matsumoto, MS, PhD2, Masayuki Hashimoto, MS, PhD2, Yukihiro Maeda1, Yoshiaki Kondo, MD, PhD1

1Department of Health Care Services Management, Nihon University School of Medicine, Tokyo, Japan; 2KDDI R&D Labs, Saitama, Japan

Abstract
A mobile electronic medical record (mEMR) system was designed that uses a Problem-oriented Contiguous Timeline View (PCTLV), which presents an overview of patient information (e.g., prescription drugs, laboratory results) along a time-axis on a single screen. Clinicians can view medical history (e.g., insulin doses, glucose levels) that relates to disease management while easily changing time-scales (day, month, year) with one click. The mEMR that uses a PCTLV may have a significant impact on clinicians’ decision-making.

Introduction
A clinician’s work is information- and communication-intensive and highly mobile. The potential for a mobile electronic medical records (mEMR) system, accessible on mobile devices such as smartphones and tablets, to improve patients’ outcomes is widely recognized. However, concerns still exist regarding barriers to mEMR use by clinicians. In a previous study, poor information overview (e.g., prescription drugs, laboratory results) and poor usability for the decision-making process were considered important barriers for clinicians1. To help address these issues, we developed an mEMR that uses a Problem Contiguous Timeline View (PCTLV), which enables visualization of patient information (e.g., prescription drugs, laboratory results, disease diagnosis) along a time axis on a single screen.

Methods and results
Figure 1 shows an overview of our mEMR system that uses a PCTLV. With this system, clinicians can view patient information (e.g., prescription drugs, laboratory results) while easily changing time-scales (e.g., hours to days, days to months) with one click on a single screen (Figure 2). Furthermore, when a clinician selects a term of interest (e.g., prescriptions, test results, clinician notes), a new window appears showing detailed information (e.g., dosage, laboratory data, and computed tomography).

Figure 1. Overview of the system

To verify the efficacy of the system, 14 clinicians within a hospital (approximately 1,300 beds, 50 clinical units, and 2,300 employees) in Japan participated in this trial. They viewed simulated patient data and their real patient data on our mEMR during the pilot test period. After this procedure, we assessed system usability using a questionnaire rating items on a five-point scale and a semi-structured interview. The information overview provided by this new mEMR was significantly higher than that of the existing EMR system (mean, 4.0 vs. 3.0 point, p=0.05). Clinicians believed this system was important in decision-making, as it was useful that all information on their patients’ drug and examination history could be obtained on a single screen. This indicates that an mEMR that uses a PCTLV was positively received.

Conclusion
The present study suggests that an mEMR that uses a PCTLV may have an important role in supporting better clinical decision-making.

Improving Failure Mode and Effects Analysis through Electronic Health Record-Assisted Team Identification

Gayle Shier Kricke, MSW¹, Matthew Carson, PhD¹, Young Ji Lee, PhD¹, and Nicholas Soulakis, PhD¹
¹Northwestern University Division of Health and Biomedical Informatics, Chicago, IL

Introduction
Failure Mode and Effects Analysis (FMEA) is a proactive risk assessment approach often used to inform healthcare quality and safety improvement. FMEA utilizes a team-based approach with expert facilitation to analyze the different ways a process may fail and to prioritize interventions addressing identified possible failures (failure modes). FMEAs are popular in healthcare because they satisfy The Joint Commission’s hospital accreditation Standard LD.04.04.05, EP 10, which requires a proactive risk assessment of a high-risk process at least every 18 months. Identifying failure modes and effects draws upon team members’ experience rather than data alone, which makes the outcome of the process largely dependent on the people at the table. Inaccuracies and inconsistencies occur if team representation is not appropriate or comprehensive.

Objective
The objective of this study was to determine whether electronic health record (EHR) documentation could be leveraged to develop a comprehensive list of providers to be represented in an FMEA process. We hypothesize that a query of EHR documentation will identify providers highly involved in healthcare processes who would be overlooked when assembling a FMEA team through typical, non-EHR driven methods.

Methods
Data Source and Variables
Data was derived from the Northwestern Medicine Enterprise Data Warehouse (NM EDW) for 3,120 Emergency Department (ED) encounters at Northwestern Memorial Hospital (NMH) between November 1, 2013 and October 31, 2014. A process map of ED workflows was created with input from ED staff. Each step in the process was mapped to documentation in the NM EDW. Variables used for analysis included provider name, provider type, activity type, and number of times the provider completed the activity during the sample of encounters.

Analysis
NM EDW documentation was then used to identify providers involved in ED workflow steps, which was compared to the process map-derived list of team members. The EHR-derived list of team members was examined to determine how the information could be used for FMEA team construction.

Results
EHR data identified 23 different process steps performed by 2,617 individual providers across 21 different provider types for the sample of ED encounters. Twelve additional provider types not included on the hand-drawn process map were identified, including two types that performed more than 5 process steps, which suggests more people may be involved in ED care than typical team assembly would identify. Within each activity, it was possible to see which individual providers performed each process step most often, which could assist in selecting the most informed providers to be invited to the FMEA process. When providers performed steps, they did so an average of 15.6 times, but individual providers with experience far exceeding the average were identified.

Conclusions
EHRs may be a useful tool in supplementing current FMEA team assembly practices by identifying engaged providers overlooked by typical process mapping, which could help improve FMEAs’ accuracy and applicability by informing the development of a more comprehensive FMEA team. Additionally, EHRs may help in prioritizing individuals to be invited to the FMEA based on their experience with process steps. Hospital quality professionals may benefit from tools that make information from the EHR quickly available for improvement planning and decision-making.
An Enterprise Clinical Data Pipeline for a Cancer Center
Emily Silgard, MS1, Tony Galuhn, BA2, Kathryn Egan, MS1,
Adam Rauch, BS2, Paul Fearn, MBA1

1Fred Hutchinson Cancer Research Center (Fred Hutch), 2LabKey Software, Seattle, WA

Introduction
To implement a scalable system for acquiring and processing unstructured or semi-structured clinical data for 350,000 historical patients and over 6,000 new cancer patients treated within the Fred Hutch/University of Washington Cancer Consortium annually, we designed an enterprise clinical data pipeline. This pipeline is meant for deployment of natural language processing (NLP) algorithms to extract data elements from clinical narratives, and for assignment, tracking, and completion of manual data abstraction, quality assurance, and training data creation.

Previous Work
This project provides a framework for developing and deploying any kind of NLP algorithm - commercial, open source, or homegrown - and for integrating annotation tasks, facilitating manual data abstraction and developing training data for NLP algorithms. Existing NLP platforms for processing unstructured text (e.g. cTAKES1) are very extensible but less precise within the cancer domain and do not include parallel manual annotation and quality assurance task management. Annotation toolkits (e.g. Brat2 and Knowtator3) do not have built-in NLP algorithms or tools. The GATE4 platform can be used for automated processing and annotation, but while it is a useful development tool, it would not be as effective for large-scale, ongoing data entry for a variety of users. Commercial NLP packages (e.g. Linguamatics5) offer many out-of-the-box options, but limit overall freedom of data models, algorithms, and application development and do not provide a platform for the creation of quality labeled data.

Methods & Materials
We have developed the data acquisition pipelines and the front-end applications that provide data exploration and visualization portals for the Hutch Integrated Data Repository and Archive (HIDRA) using LabKey Server6, an open source platform that helps translational research teams integrate, analyze, and share clinical data. We use LabKey Server for instantiating the NLP engine and parametrizing the processing pipeline. The pipeline has a hierarchical design where each level is linked to a separate directory containing python scripts/modules, text file gazetteers, dictionaries and metadata needed to extract the relevant set of data elements. The first tier corresponds to document types and the second to disease groups. Document types can differ greatly in discourse and data elements. They may come from disparate clinical source systems, and may have varying formats and metadata, requiring customized parsing and pre-processing. The current design will allow us to take advantage of existing NLP tools and algorithms where relevant, while having the flexibility to develop our own algorithms for enterprise specific definitions and data elements which do not have existing, well-established NLP algorithms.

Testing and Evaluation
We will evaluate each function of the pipeline with end users (developers, abstractors, researchers) through common workflow scenarios. Performance of the NLP algorithms will be evaluated for the pilot against data entered by trained medical abstractors for a subset of records for which results and detailed error analysis will be reported.

Discussion
Next steps include extending the pipeline to other cancer types, ideally involving minimal development of new, disease-specific algorithms and dictionaries, as well as extension to other document types. The enterprise pipeline would ideally be portable to any group or organization utilizing a similar information model and any existing or home grown NLP algorithms could be implemented within its framework. While initial parsing and preprocessing of clinical documents would have to be tailored to match organization-specific sources and formats, the bulk of the data elements needed for cancer research remain relatively similar throughout the cancer research community.

Abstract: Identification and subsequent addition of elements to a “home-grown” ambulatory electronic health record (EHR) system can yield useful resources for primary care providers in Patient Centered Medical Homes (PCMH) in the areas of care planning, patient self care support, and new medication management. Opportunities for the EHR to support PCMH goals were identified with new system functionalities added to help practices bridge gaps in documentation needed to achieve National Committee for Quality Assurance (NCQA) Recognition.

Introduction: Primary care practices seeking recognition as Patient Centered Medical Homes must undergo a rigorous process and meet thresholds for particular elements, some of which are assessed through chart review. In this study, we identified areas in which practices seeking PCMH recognition had difficulties meeting certain documentation requirements. In response, changes were made to the EHR to better support these functions. We analyzed the transformation of practices once these new functionalities had been implemented to gain insight to the benefits of these new features.

Methods: By conducting pilot chart reviews of eight patients per practice, we identified four areas of difficulty meeting documentation requirements for 22 primary care practices during 2014 in preparation for a subsequent full chart review as part of the NCQA application. These included developing care plans with treatment goals, providing patients with self management plans with goals, and providing information about and assessing patient understanding of new medications. We worked with the practices as well as with HIT developers to make modifications within the EHR system, which included templates to satisfy care plans and self management plans with goals, as well as “Patient Educated” and “Patient Understands” checkboxes for prescribed medications. Practices were encouraged to use the new functionalities for documentation to meet these factors. We then conducted full chart reviews of 48 patient charts per practice. We assessed and compared the pilot and full chart review findings for the practices.

Results:

Table 1. Changes in percent of charts passing documentation requirements pre and post new EHR functionality

<table>
<thead>
<tr>
<th>Documentation Requirement</th>
<th>Pre-EHR Intervention</th>
<th>Post-EHR Intervention</th>
</tr>
</thead>
<tbody>
<tr>
<td>Care plan with treatment goals</td>
<td>18%</td>
<td>95%</td>
</tr>
<tr>
<td>Self management plan with goals provided to patient</td>
<td>9%</td>
<td>100%</td>
</tr>
<tr>
<td>Information about new medication given to patient</td>
<td>36%</td>
<td>54%</td>
</tr>
<tr>
<td>Understanding of new medication assessed</td>
<td>77%</td>
<td>95%</td>
</tr>
</tbody>
</table>

As shown in Table 1, the percentage of the practices meeting passing criteria for each of the four factors increased after new EHR functionality was implemented.

Conclusion: Modifications to the EHR system tailored to primary care practices can assist in supporting care processes and may ease the burden of documentation requirements to become NCQA recognized as Patient Centered Medical Homes. After EHR system modifications, practices’ scores improved in four important care process areas, making it evident that additional EHR documentation support was a major contributor to improved scores.

A New, Touch-screen Sensitive Display for Management of Diuretic Therapy of Heart Failure Patients in Critical Care Setting

Jiri Sklenar, Ph.D., Jay Parikh, M.D., James O. Mudd, M.D.
Knight Cardiovascular Institute, Oregon Health & Science University (OHSU), Portland, Oregon

Abstract

The user experience of providers taking care of heart failure patients can be improved by augmenting existing EMRs with touch screen displays and custom-developed applications. Putting providers in the driver’s seat from the very beginning of the developmental process is essential for the overall success. Our methodology can be applied to other medical areas as well.

Introduction

Providers using current EMRs are confronted with large amounts of data, but paradoxically an intuitive access to clinical information is not always readily available. Deriving actionable information from a multitude of discrete data elements remains a time-consuming, tedious, and potentially error-prone process, due to requisite navigation through a number of screens and menus. This problem becomes compounded when providers are caring for complex multiple co-morbid illnesses such as heart failure patients.

Hypothesis

We therefore hypothesized that using touch-screen technology with standard data interfaces from the EMR, and custom-developed software, we can design an intuitive and responsive tool for busy providers, to assist them in answering important clinical questions almost immediately, without any need to navigate through multiple screens of text and graphs. This was specifically piloted in hospitalized heart failure patients to rapidly assess changes in volume status, weight and renal function in response to a given dose, class and route of diuretics.

Results

Using our application (Figure 1) we were able to more quickly answer clinical questions in seconds, compared to minutes when only tools available in the EMR were used.

Conclusion

Using a portable tablet, we designed a flexible software system allowing for rapid assimilation of multiple data elements into a simple user interface to augment clinical decision-making. The lessons learned are not specific to heart failure patients only, and will be easily applicable to other areas of healthcare in caring for patients with complex chronic medical conditions.

Introduction

The purpose of clinical research is to produce evidence for clinicians to use to support patient care. However, using information from clinical studies for clinical decision making requires significant cognitive effort and time. In this pilot study we designed alternate information displays for presenting the results of clinical studies to clinicians. We hypothesized that, compared to traditional narrative formats, a structured display improves clinicians’ ability to scan, judge the relevancy, and interpret the findings of clinical studies.

Methods

We compared two alternatives for displaying clinical studies with standard display provided in PubMed’s search results. The first display provides a narrative summary with the abstract title, journal, publication date, and study conclusions. The second display presents key study elements in a structured tabular format according to the PICO framework (population, intervention, comparison, and outcome)¹. The displays were iteratively designed and presented to members of our research team and target users for feedback. The overall design principle was to present only the information necessary to help clinicians judge the relevancy of a study to a specific patient and to interpret the gist of the study findings. Twelve physicians were invited by email to participate. Participants viewed three brief vignettes along with five studies that were randomly presented in one of the three display formats. The five studies were pre-searched by the study team so that all participants were exposed to the same studies. Participants were then asked to rate each display using an 11-item Likert scale questionnaire (1=strongly disagree; 7=strongly agree), which included items from the Simple Usability Scale (SUS)² and measurements of participants’ ability to judge relevancy and interpret study findings.

Results

All twelve invited physicians participated in the study. The PICO table rated 1.5 to 3.0 points higher than PubMed as the baseline and 0.1 to 0.9 higher than the narrative summary. Averaging all 11 questionnaire items, subjects favored the PICO table compared to the text summary and PubMed (5.9 vs. 5.6 vs. 4.0). Figure 1 shows a subset of the individual rating criteria.

Discussion

A structured format according to PICO elements is a promising way of improving clinicians’ use of clinical studies to support patient care decision making. Limitations include a relatively small sample size, although sufficient given the exploratory nature of the study. A study with a larger sample size is underway.

4The Department of Biomedical Informatics, New York Presbyterian Hospital, New York, NY, USA
5The Department of Anesthesiology, New York Presbyterian Hospital, New York, NY, USA

Introduction:
When patients seek care across multiple clinical settings there is a risk of the fragmentation of clinical data, including medical imaging records. Health information exchanges (HIE) are expected to reduce potentially avoidable duplicate imaging, improving the quality and cost of health care. In the future, it may be possible to alert ordering clinicians across an HIE when a potentially avoidable duplicate study is ordered, but more work is needed before alerting rules can be developed based on the anatomical location of studies from multiple sites. When patients receive computed tomography (CT) scans at different institutions they can be categorized as same (the exact same CT based on identical Logical Observation Identifiers Names and Codes (LOINC)), similar (same anatomical region but different CTs/LOINC codes, such as CT head and CT orbits), or proximate (different CTs/LOINC codes but in proximate anatomical regions such as CT head and CT neck), and it may be desirable to identify these as potential duplicates. However, no anatomical framework yet exists for the identification of similar or proximate CTs. We propose a novel anatomical semantic ontology that categorizes LOINC codes for CTs into general anatomical regions, allowing identification of anatomically similar and proximate CTs to facilitate alerting via a HIE-based duplicate detection system, and future analyses employing this framework.

Methods:
The New York Clinical Information Exchange (NYCLIX) was the source for de-identified reports of all patients who received CTs from the six participating sites in the HIE between 3/09 and 7/12. Site-specific proprietary names for each class of CT scan were mapped to LOINC codes for comparison across sites using a previously described mapping process. (Beitia, AMIA 2013) Each LOINC code was then assigned by two of the authors up to five of nine possible independent anatomical identifiers from our novel ontology, based on the type of CT and its anatomical location. These included: head, neck, chest, abdomen, pelvis, left and right upper as well as left and right lower extremities. For instance, LOINC code 44115-4 (Abdomen and Pelvis CT) was assigned two anatomical identifiers for abdomen and pelvis, as was 24964-9 (Spine Lumbar CT W contrast IV). Inter-rater reliability was analyzed using the Kappa statistic. Twelve additional common combinations of proximate anatomical identifiers were recognized, such as “chest and abdomen”. This system resulted a total of 21 possible individual or combinations of anatomic identifiers. Those studies that lacked appropriate description were labeled unknown and excluded. For the extremities, when no laterality was specified, the study was presumed to be bilateral. The number of successful matches was then calculated for the individual or combined anatomic identifiers.

Results:
717,231 CT scans were mapped to 217 different LOINC codes. Twenty-three (10.6%) of these LOINC codes, accounting for 8,252 (1.15%) CTs were excluded because they lacked appropriate description and the anatomical region was unknown. This resulted in 708,979 CTs mapped to 194 LOINC codes in our dataset that underwent anatomic identifier assignment. Inter-rater reliability was found to be $\kappa=0.89$ (p<0.001). The most frequently imaged region of the 9 independent anatomical identifiers was the head, which accounted for 262,121 (27.3%) of all studies. When comparing the 21 independent or combination anatomical identifiers, the head was included in 248,741 (35.08%) of studies while combined abdomen and pelvis accounted for 174,966 (24.68%) of studies.

Conclusions:
Our novel anatomical semantic ontology should aid in the identification of similar and proximate CT scans across multiple sites in an HIE, laying the groundwork for future HIE-based alerting systems to inform clinicians that same, similar or proximate prior CTs exist for a patient. Such a system could potentially reduce avoidable duplicate imaging, and improve the quality and safety of care while reducing costs. Next steps include an analysis of the actual rates of same, similar and proximate CTs across multiple sites in a large HIE dataset.
Leveraging Genetic Findings to Identify High-Risk Chronic Kidney Disease in the Electronic Medical Record

Craig Smail, MA MSc
1Biomedical Informatics Training Program, Stanford University, Stanford, CA

Abstract

Black Americans with chronic kidney disease (CKD) progress faster than Whites to end-stage renal disease. A variant in the apolipoprotein L, 1 (ApoL1) gene is associated with faster-progressing CKD, explaining most of the observed difference. The variant leads to CKD sub-types with distinct, shared phenotypes that are sometimes recognized by clinicians, who tend to assign diagnoses of hypertensive nephropathy. Using these insights, the objective was to identify patients with ApoL1-like CKD using only clinical data.

Introduction

Twenty-six million Americans are currently diagnosed with chronic kidney disease (CKD) and, amongst those affected, Blacks are approximately twice as likely as Whites to progress to end-stage renal disease (ESRD)1. The results of recent GWAS show that Blacks homozygous for a missense mutation in the apolipoprotein L, 1 (ApoL1) gene have a 10- to 29-fold greater risk for CKD1. This ApoL1-associated CKD is of a spectrum of three hypertension-related sub-types, with shared, distinct phenotypes2, and explains most of the increased rate of ESRD in Blacks. The variant is found almost exclusively in those of recent West African ancestry. The co-occurrence of hypertension with this sub-type of CKD often leads to an unspecific clinical diagnosis of hypertensive nephropathy.

Given the above findings, the aims of the present study were to: (1.) combine known phenotype similarity, diagnosis patterns and disease prevalence of ApoL1-associated CKD to identify a cohort of Black patients with putative cases, using only clinical data; (2.) compare results with previous findings obtained from patients with known ApoL1 risk-variant (Chronic Renal Insufficiency Cohort).

Methods

The method presented here (1.) uses hierarchical clustering of a standardized matrix of lab values to identify clinically similar CKD patients, (2.) picks the highest-rank cluster by frequency of patients with a diagnosis of hypertensive nephropathy (putative ApoL1 high-risk cohort), and (3.) constructs a control cohort (putative ApoL1 low-risk cohort) matched on time since CKD diagnosis of patients appearing in the top-ranked cluster from step (2.). The method was run on two separate datasets (primary and validation) and a combined dataset.

Results

Similar differences in rate of annual decline in kidney function (as measured by estimated glomerular filtration rate) were observed in putative ApoL1 low- and high-risk Black patients in primary, validation, and combined datasets (combined dataset: -0.4±2.8 ml/min/1.73m² low-risk vs. -3.0±5.8 high-risk; t-test, p=0.03) but were equivalent when applying the method to a control cohort of White patients (-1.2±2.8 vs. -1.6±2.5; t-test, p=0.15). By comparing the clinical profiles of both Black cohorts, the observed results were not explained by baseline differences in kidney function, time since diagnosis of CKD, blood pressure, age, gender, or diagnostic history of hypertension. Similar rates of decline in kidney function were observed in the Chronic Renal Insufficiency Cohort.

Conclusion

Even without known genotype, the method repeatedly identified a cohort of patients with rate of annual decline in kidney function consistent with a previous study using patients with known ApoL1 genotype. Furthermore, the results help disambiguate the role of hypertension as a cause of faster-progressing CKD observed in Black patients.

A Platform for Generating and Validating Breast Risk Models from Clinical Data: Towards Patient-Centered Risk Stratified Screening

Nova F. Smedley1,3, Ngan Chau2, Antonia Petruse2, Alex A.T. Bui PhD3, Arash Naeim MD PhD2, William Hsu PhD3
1Department of Bioengineering; 2Athena Breast Health Network, Jonsson Comprehensive Cancer Center; 3Medical Imaging Informatics Group, Department of Radiological Sciences, University of California, Los Angeles, CA

Introduction. Breast cancer prevention is often the center of great debate as to who should be screened and whether current screening policies are effective. In 2005, the Institute of Medicine advocated integration of technology, biology, and risk stratification for the development of screening models in breast cancer, noting that personalization could improve the predictive value of the screening test and ensuing interventions. Last year, the Nelson et al. enumerated 13 general risk models and 50 studies on BRCA prevalence to voice the need to update breast cancer screening recommendations. Today’s current risk models do not adequately reflect the increasing importance of quantitative imaging and gene expression as biomarkers for disease prediction. This work presents an informatics platform that integrates multimodal data sources (demographics, clinical, imaging, genomic, outcomes) with statistical tools to validate and generate risk models in a cohesive manner using observational clinical data collected on screening patients. The platform addresses challenges related to managing and processing this growing repository of patient data for the purposes of personalized risk-stratification.

Methods. With institutional review board approval, we developed a relational database tied to a high-performance cluster (HPC) and cloud storage solution that was Health Insurance Portability and Accountability Act (HIPAA) compliant. Our initial work focused on 1,401 patients enrolled through the Athena Breast Health Network, which was recently funded to study the effectiveness of personalized screening regimens. Patients completed a questionnaire that asked about breast cancer related risks (e.g., family history, hormonal factors). Imaging-derived information (e.g., BI-RADS scores), diagnostic tests (e.g., biopsies, molecular analysis), and other clinical information (e.g., comorbidities) were extracted from electronic health records (EHR). Initially, patients were mapped to the most common risk model for breast cancer screening and diagnosis: the 1989 Gail model with subsequent refinements. The model’s risk factors have been incorporated or found in other subsequent popularized models, demonstrating their validity over time in measuring the relative risk of an individual developing breast cancer. The HPC provided a centralized location for processing raw patient data and run preprocessing steps such as sequence alignment (for patients with biospecimens collected) and breast density quantification (from unprocessed mammography images). Whenever possible, data from the EHR were used to infer missing information needed to instantiate these models. Risks were validated by stratifying patients in terms of their clinical indication of where they fall along the diagnosis guidelines. To generate improved models, statistical analysis (e.g., logistic regression) can be performed using the captured data to further formulate models that incorporate novel features (e.g., gene expression, quantitative breast density); these models can then be validated using data on the population to determine whether additional features improve predictive performance.

Discussion. We present preliminary work on establishing an informatics platform that leverages high performance computing infrastructure at our institution to manage and process protected health information. Our initial efforts have focused on breast screening and improving risk stratification models, but this platform will be generalized to other clinical domains (e.g., other cancers, neurological diseases) as well. Using the platform, we identified that 36% of patients with a Gail score of over 2 had a confirmed diagnosis of cancer; our initial experiences in establishing this infrastructure has enabled us to quickly create and validate improved models of individualized risk.

Systemic Risk Analysis for Use Cases for Safety-Related Usability of EHRs

Michael W. Smith, PhD¹, Daniel R. Murphy, MD, MBA¹, Dean F. Sittig, PhD², Elise Russo, MPH¹, Hardeep Singh, MD, MPH¹
¹Michael E. DeBakey VA Medical Center and Baylor College of Medicine, Houston, TX
²University of Texas Health Science Center, Houston, TX

Introduction

Usability is critical to electronic health record (EHR) safety. However, there is little guidance on what use cases to target in a usability evaluation for improving EHR-related safety. While basic use cases have been proposed, they do not incorporate how user interactions with an EHR are affected by multiple socio-technical dimensions of the EHR-enabled healthcare delivery system. Targeting all the different permutations of user persona, clinical content, hardware, and workflow would be impossible. However, newer risk analysis methods, developed for application in complex socio-technical systems, may offer a means for informing the development of use cases for evaluating usability for EHR-related safety. The Functional Resonance Analysis Method (FRAM)¹ focuses on variability in the performance of a function (i.e., an action, such as ordering a test, that produces an outcome necessary to achieve a goal) and how it can interact with variability from other coupled functions. This can lead to conditions that exceed what can be managed safely. The aim of this analysis is to use FRAM to study the functions (and their interactions) involved in follow-up of abnormal test results in outpatient care settings using EHRs, in order to inform the development of key use cases to detect usability issues impacting safety.

Methods

We interviewed a total of 50 staff involved with testing processes at three large clinics, including lab, radiology, IT, and primary care personnel. From these interviews, we identified functions and factors directly related (“core functions”) or indirectly related (“support functions”) to abnormal test follow-up. We then developed the FRAM model in a stepwise process. We assessing the potential variability encountered in each function using an 8-dimension socio-technical model to encompass different sources of variance in performance. For example, the performance of the function Order test can vary in duration and risk of error depending on the complexity of the patient and the EHR training of the provider. To identify elements for inclusion in use cases for evaluation for EHR safety, we looked for functions and sources of variance that had impact throughout the full set of functions.

Results

Upstream functions influenced the timeliness and reliability of test result follow-up. In primary care, the number and complexity of patients influenced the time used for three core functions: Order test, Obtain test sample/radiology images, and Find test results in EHR inbox. They also constrained the support function Maintain time for administrative tasks, which served as a resource for two core functions, Find test results in EHR inbox and Order follow-up, and for two support functions, Detect and fix problems in test orders, and Maintain training on EHR (which itself is a resource for Order test and Find test results in EHR inbox). In the area of diagnostic services, patient number and complexity also affected Ensure the functioning of lab & imaging capabilities, which is a resource for Update list of test order options in EHR and Detect and fix problems in test orders. These findings indicate that time pressure and number of tests are key factors affecting performance throughout the process. The functions Detect and fix problems in test orders, Maintain training on EHR, and Update list of test order options in EHR compete with time demands but can save time in the long run. Based on these results, example use cases with a safety focus that encompass these elements could include: 1) The user must detect a problem with a test order (e.g., out of date orderable item) under conditions of time pressure and a large volume of orders; and 2) The user must order a test under conditions of minimal training and a list of order options that includes some out-of-date choices.

Conclusion

FRAM can be used to identify functions and factors that are important for safety of abnormal test result follow-up in EHR-enabled healthcare systems, and can inform key use cases to detect important safety-related usability issues.

Prediction of Colorectal Surgical Site Infections Using Risk Factors

Sunghwan Sohn, PhD1,2, Majid Rastegar-Mojarad, MS1,2,6, James M. Naessens, ScD1,3, Elizabeth B. Habermann, PhD1,3, David W. Larson, MD4,5, Hongfang Liu, PhD1,2
1Department of Health Sciences Research, 2Biomedical Statistics and Informatics, 3Health Care Policy and Research, 4Department of Surgery, 5Division of Colorectal Surgery, Mayo Clinic, Rochester, MN; 6Department of Health Informatics and Administration, UW-Milwaukee, Milwaukee, WI

Introduction

Surgical site infection (SSI) is the most common healthcare-associated infection, accounting for 31% of all hospital inpatient infections and resulting in increased length of hospital stay and cost. The patient characteristics in National Surgical Quality Improvement Program (NSQIP) can be regarded as potential factors in predicting SSI. In this study, we analyzed perioperative risk factors from both NSQIP data and clinical notes and further employed a Bayesian network classifier to investigate the prediction capability of SSIs using those risk factors.

Materials and Methods

We used NSQIP data from colorectal surgery (CRS) performed at the Mayo Clinic Methodist hospital from 2010 to 2012. This consisted of 751 surgery cases with 67 SSIs (i.e., 36 superficial incisional SSIs, 5 deep incisional SSIs, and 26 organ/space SSIs). A Bayesian network was developed to detect SSIs using risk factors in both NSQIP data and clinical notes. The SSI risk factors we used are: 1) pre-operation: age, gender, smoking status, pre-op hospital stay, diabetes, anemia†, BMI, steroid use, blood transfusion, prior operation; 2) intra-operation: ASA score, operation type, wound classification, duration of operation, laparoscopic vs others; 3) post-operation: anemia†, ascites, wound disruption, abdominal tenderness†, antibiotics†, fever† († denotes variables extracted from clinical notes using natural language processing; the other variables are from NSQIP data).

Results

Table 1 shows the ROC area under the curve (AUC) of the Bayesian network classifier using different sets of variables with 10-fold cross validation. For comparison, a logistic regression was also employed (corresponding ROC curves are shown in Figure 1). Both methods produced relatively high specificity but low sensitivity. The basic statistics and odd ratios of patient characteristics were also examined, and these are described in Table 2.

Discussion

Certain patient characteristics can be used as risk factors to predict SSIs. A Bayesian network performed better than a traditional logistic regression for the prediction. For real-time SSIs surveillance those risk factors can be utilized supportively along with SSI indicative keywords from clinical narratives to accurately monitor SSIs.
Representing and Validating Cancer Study Metadata Standard Using RDF Shapes Expression Language

Harold R. Solbrig¹, Eric Prud’hommeaux², Christopher G. Chute³, Guoqian Jiang¹
¹ Department of Health Sciences Research, Mayo Clinic, Rochester, MN; ² W3C/MIT, Boston, MA; ³ Johns Hopkins University, Baltimore, MD

Abstract

The RDF Data Shapes Working Group is developing a W3C Recommendation for the Shapes Constraint Language (SHACL), which formally describes structural constraints on instances in Resource Description Framework (RDF) graphs. The objective of this study is to create a publicly available SHACL-based schema that defines a common way to represent the subset of the ISO/IEC 11179 Metadata Repository data element model in RDF. The goal of this project is to be able to produce a shared and extensible set of tools for validating and harmonizing data element definitions within the RDF / OWL environment and, in the longer term to use these harmonized definitions to validate, transform and integrate disparate cancer study data into cohesive and consistent repository.

Introduction

ISO/IEC 11179 Common Data Elements (CDEs) are used to support the semantic interoperability and aggregation of research data from disparate sources¹. The National Cancer Institute (NCI) has developed a cancer study data standard repository (caDSR)¹ based on the ISO/IEC 11179 metadata registry standard² that is used to describe and annotate CDEs in the cancer study domain. We have been developing a Resource Description Framework (RDF) triple store in combination with a Web Ontology Language (OWL) reasoner to validate CDE definitions and integrate them across domains. While this is producing promising results on a local level, the real advantages of the approach will come from scalability -- the ability to apply and extend tools for use across multiple domains and situations.

The Resource Description Framework (RDF) Shape Constraint Language (SHACL)³ provides a number of interesting opportunities along this front, including:

- Publishing and sharing the RDF model used in a given ISO 11179 compliant RDF Data Set or Triple Store;
- The ability to validate and transform external data into a shared structure and format;
- The ability to transform the definitions of the ISO 11179 Data Element definitions into SHACL Shape Constraints for use in validating and integrating the target data.

Methods and Results

In this pilot study, we focused on core data meta-model defined in Part 3 of the ISO/IEC 11179 standard², including definitions of: Data Element, Data Element Concept, Object Class, Property, Value Domain, Permissible Value, Conceptual Domain and Value Meaning. We used a simple representation of SHACL called as Shape Expression (ShEx)⁴ to define the target meta-model attributes. We then used these definitions in combination with a ShEx based validation tool to drive and verify the transformation of a subset of the NCI caDSR Common Data Elements from XML to RDF. Our next steps will include: 1) A tool that will allow us to generate ShEx rules that describe the instance data described in the NCI caDSR repository. 2) A tool to transform UML models into SHACL equivalents. In summary, the pilot study provides useful insight into the strength of the SHACL-based framework for representing and validating cancer study metadata standards.

PubMed ‘Early Alerts’: A Pilot Study to Support Prospective Detection of Emerging Adverse Drug Events

Alfred Sorbello1, DO, MPH; Anna Ripple2, MLS; Olivier Bodenreider2, MD, PhD  
1US Food and Drug Administration, Center for Drug Evaluation and Research, 10903 New Hampshire Avenue, Silver Spring, MD 20993, USA. 2Lister Hill National Center for Biomedical Communications, U.S. National Library of Medicine, 8600 Rockville Pike, Bethesda, MD 20894, USA.

Background: The FDA traditionally monitors the safety of marketed drugs by analyzing reports submitted by manufacturers and consumers to the FDA Adverse Event Reporting System (FAERS). In order to enhance prospective detection of emerging adverse drug events (ADE), we investigated leveraging existing PubMed “MyNCBI” functionalities and searching resources to survey the biomedical literature for the latest published safety information in the use case of the new oral hepatitis C drugs.

Methods: Using PubMed “MyNCBI” cubby functionality, we established a search strategy designed to retrieve citations most recently added to PubMed and provide automated weekly emails (PubMed ‘Early Alerts’) with abstracts and links to available full text citations. The search strategy (Table 1) includes three criteria: (1) Drugs of interest; (2) Citation scope: citations from MEDLINE journals, as soon as they are entered in PubMed (prior to indexing); (3) Time Period: week of interest.

<table>
<thead>
<tr>
<th>(“drug A”[all fields] OR &quot;drug B”[all fields] OR …)</th>
<th>Drugs of interest conjoined with the Boolean operator OR and searched in all fields including the Title, Abstract, and other terms (including Author Keywords) fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td></td>
</tr>
<tr>
<td>((publisher[sb] NOT pubstatusnihms[All Fields] NOT pubstatuspmcsd[All Fields] NOT pmcbook[All Fields]) OR inprocess[sb])</td>
<td>Includes citations supplied by publishers that are not yet indexed and have not completed quality control, and includes citations in the review process; Excludes citations from non-MEDLINE journals (author manuscript or publisher-supplied citation submitted to PMC under the NIH Public Access Policy, book or book chapter citations available on NCBI bookshelf)</td>
</tr>
<tr>
<td>AND</td>
<td></td>
</tr>
<tr>
<td>“2015/Month/Day 15.00” [MHDA]:&quot;2015/Month/ 7 Days Later 15.00” [MHDA])</td>
<td>Restricts the search to a 7-day time period; MHDA is automatically added by PubMed for each weekly search—this is one of the parameters that can be set when stored searches are set up in the NCBI cubby.</td>
</tr>
</tbody>
</table>

Results: A typical weekly PubMed ‘Early Alerts’ email delivery consists of 12-15 citations from domestic and international journals spanning 5-8 oral hepatitis C drugs of interest. The citations reflect human, animal, and in vitro research from the US and other countries with varied publication types, including reviews, letters, clinical trial reports, pharmacokinetic studies, case reports, and observational studies. Our search strategy is designed for recall. Its precision can be increased significantly by requiring the presence of specific words in the titles or abstracts (“safety”, “toxicity”, “adverse”, and “tolerability”).

Conclusions: By leveraging existing PubMed “MyNCBI” functionalities and searching resources, we can more efficiently canvass across a broad range of journals and publication types in PubMed for the latest drug safety data. This approach lessens reliance on time-consuming and often inefficient ad hoc searches, and it complements traditional approaches to finding relevant safety information on drugs of interest. Evaluation by FDA Medical Officers and Safety Evaluators indicates that the PubMed ‘Early Alerts’ complements their efforts to discover emerging ADEs as part of their regulatory review activities.

Disclaimer: The views expressed are those of the authors and do not necessarily represent the views of the US FDA, the NIH, or the US Government.
Annotating ADLs and IADLs in Veterans Affairs Clinical Documents

Brett R South, MS, PhD1,2, Danielle L Mowery, PhD1,2, Lee Christensen, MS1,2, Adi V Gundlapalli, MD, PhD1,2, Melissa Tharp, BS2, Marzieh Vali, MS3, Marjorie Carter, MS2, Mike Conway, PhD2, Salomeh Keyhani, MD3, Wendy W Chapman, PhD1,2
1VA Salt Lake City VA Health Care System, and 2University of Utah, Department of Biomedical Informatics, Salt Lake City, UT, 3San Francisco VA Medical Center, San Francisco, CA

Abstract Descriptions of six activities of daily living (ADLs) and seven instrumental activities of daily living (IADLs) are documented in unstructured U.S. Department of Veterans Affairs (VA) healthcare data. Natural Language Processing (NLP) can be used to extract this information from clinical free-texts to predict the likelihood of nursing home admissions after inpatient admission or as measures of functional status in risk adjustment. We assess annotation guidelines for ADLs/IADLs used to build a reference standard for NLP algorithm development and report descriptive statistics describing prevalence, inter-annotator agreement, content structures, and mention prevalence for explicitly described functional impairment.

Methods We constructed a cohort of 1,000 patients admitted for congestive heart failure, acute myocardial infarction, pneumonia, and stroke and extracted their clinical documents (n=353,889) for calendar year 2012 extracted from the VA’s Corporate Data Warehouse. We randomly sampled 180 documents from a physician-reviewed document set (n=52,304) targeting those documents most likely to contain mentions of ADLs/IADLs: Nursing Assessments, Social Work consultations, Occupational/Physical Therapy, ER Physician, Primary Care, H&P, Critical Care, and Discharge Summaries. Using eHOST1, two reviewers independently annotated mentions of ADLs/IADLs: a third reviewer arbitrated disagreements creating a reference standard using a previously developed schema and guideline2. We conducted post hoc analysis to classify mentions into ADL subcategories (Bathing/Hygiene, Dressing, Eating, Toileting, Transferring, Walking) and IADLs (Communication, Managing finances, Managing Healthcare, Home Maintenance, Preparing meals, Shopping, Transportation). We determined whether the annotated mentions describe functional impairment and where implementation of an algorithm like ConText3 would be warranted for classifying impairment. We report inter-annotator agreement, ADL/IADL prevalence, content structures (i.e. semi-structured input vs narrative), and mention prevalence for descriptions of functional impairment.

Results In the text set of 180 documents, a total of 1,490 (8.7 per document) for ADLs/IADLs were annotated. Inter-annotator agreement was 71% (substantial agreement) for annotation of ADL/IADLs. The bulk of these observed annotations (800, 54%) were ADLs classified into Bathing 74 (9%), Dressing 36 (4.4%), Eating 75 (9.1%), Toileting 175 (23.7%), Transferring 81 (9.9%), and Walking 245 (29.8%). IADLs represented only a small number of annotations containing only five of the seven categories including Managing Finances 2 (<1%), Managing Healthcare 2 (<1%), Home Maintenance 12 (1.5%), Preparing meals 3 (<1%), and Shopping 2 (<1%). Only 22% were generated from narrative descriptions; the majority were components of semi-structured text input, such as tables or question/answering templates, which are not easily classified with standard NLP techniques. The majority of ADLs/IADLs did not imply functional impairment - only 177 (21%) explicitly stated the patient was functionally impaired for that given category.

Conclusions Additional work will involve developing rules to deal with situations where the ADL/IADL is mentioned as part of semi-structured text or where additional contextual information is required to determine functional impairment. Developing NLP algorithms that reliably extract ADLs/IADLs scaled to large patient cohorts will pose challenges but will produce useful predictors of healthcare outcomes.

Inexpensive Radio Communications System for Wheelchair Users

James R. Sprague, Dorothy Curtis, MIT/CSAIL, Cambridge, MA, USA

Abstract
Wheelchair-bound residents of assisted living facilities sometimes require assistance from staff when they are isolated or away from existing call buttons. Those with limited manual dexterity could use this system when their wheelchair slips off the sidewalk. Getting help in this situation is especially important to users with advanced multiple sclerosis, who are at risk when exposed to excessive heat. This project conducted a Proof-of-Concept trial using two-way radios to allow residents of an assisted living facility to communicate with staff members from their wheelchairs. The radios were effective and reliable on the facility campus. For certain subsets of this population they appear to be a helpful and cost-effective assistive technology.

Overview

The Boston Home (TBH), based in Dorchester, Massachusetts, is a not-for-profit specialized care residence for adults with advanced Multiple Sclerosis and other neurological diseases. 4 wheelchair-bound residents volunteered to have their chairs equipped with a Family Radio Service (FRS) band radio in a standardized enclosure with a custom-mounted microphone, speaker, and Push-to-Talk switch. A staff member carried a standard FRS radio during normal business hours. All communications with this system were broadcast over an open channel which could be heard by anyone in the trial or anyone else nearby with proper equipment, so there was no expectation of privacy. Residents were notified of privacy issues and then allowed and encouraged to use the system as they saw fit. All uses of the system were centrally recorded and later reviewed and tallied. Exit interviews were conducted at the end of the 6 week trial.

Trial Results

Post-trial analysis of the trial confirmed that there were no uses of the system to address urgent needs, though no participants reported an urgent situation where the system failed. All users reported having temporarily muted the radios during activities classes or other group activities, but none of them requested that the radios be removed before the end of the trial. All participants felt that the system could be useful for urgent communications, especially in summer months when they are more likely to be outside on the facility grounds.

Analysis of the recordings also showed that most uses of the system were for confirming/testing the operation of the system, combined with social interactions with the staff. The system was used on occasion to locate individuals or to schedule visits to the wheelchair repair facility. Over the course of the trial, daily uses dropped off substantially from a one-time peak of 20 to less than one per day on average. This is attributed to the waning novelty of the system over time.

Conclusions

The trial was considered a success as a Proof-of-Concept. Each radio required less than $100 in parts and required no ongoing licensing fees or external infrastructure (e.g. WiFi). This can be compared to $20 for a low cost cell phone + $40/year for service, assuming the user has the dexterity to use the cell phone. (Interested readers are referred to Technology Assessment of Communication Systems for Wheelchair Users in an Assisted Living Setting for more information on comparative costs). The radios worked reliably across the TBH campus (approximately 500’x500’). Participants appeared to enjoy having direct access to the staff, and believed that the radios could be useful in an urgent situation. In its current form, this system would be unsuitable to those with extensive speech, hearing, or upper body motor deficits, though some enhancements have been proposed that would expand the target population.
Machine-to-Machine (M2M) Communication in Home-care
Basile Spyropoulos, PhD, Aris Tzavaras, PhD and Maria Botsivaly, MSc.
Technological Educational Institute (TEI) of Athens, Athens, Greece

Abstract
The purpose of this work-in-progress paper is to present the status of our attempts to utilize "hybrid" Machine-to-Machine (M2M) Communication, in Home-Healthcare. M2M communication and the Internet of Things (IOT) are growing quickly and we consider that they will be soon adopted in Home-Healthcare and Point-of-Care testing systems, because of their advantages, concerning interoperability and automation of the said systems.

Introduction
There are a lot of emerging technologies during the last five years that allow for “Machine Type Communication, MTC” leading to a new “Internet of Things, IOT”, enabling “Machine-Cooperation” without human intervention.

Methods and Resources
The purpose of this work-in-progress paper is to present the status of our attempts to utilize “hybrid” M2M-Communication, in Home-Healthcare. We use the term “hybrid systems” since the systems under development, must comprise of, due to their Healthcare related tasks, both, human mediated and machine-only “operation modes”. We are presently focusing on the following Home-care tasks, as displayed in Figure 1 (right).

Results
We have adopted the approach and the terminology of the International Telecommunication Union (ITU) and more specific, the M2M service layer and architectural framework requirements [1], the Application Programming Interface (API) [2] and Protocols and the remote patient monitoring/assisted living requirements (RPM/AL) [3]. Data are transferred from sensors linked to the patient, forming a body area network (BAN), to a gateway that manages the sensors and it can be continuous or periodic, depending on the sensor and the Biosignal types. The acquired data are stored in a gateway and/or uploaded to a Medical Information System, located in a Wide Area Network. In the gateway, the data are linked to the patient demographics. Caregivers, such as Medical Doctors, Nurses etc. can access the Patient’s personal information, in accordance with privacy and security requirements.

Conclusion
We have described briefly our efforts to make use of ITU-compliant M2M-Communication in Home-care and in PoCT, taking into account the “state-of-art” presented in Figure 1 (left) and looking for the ICT-Standards’ Essential-Patents possibly involved [4]. The system is presently still under development and it is being tested by comparing the automatic performance of each function to the manual one.

Bringing Context to Data Analytics: A Hybrid Approach to Understanding Clinical Workflow

Bryan Steitz¹, Kim M. Unertl, PhD, MS²
¹The Pennsylvania State University, University Park, PA; ²Vanderbilt University School of Medicine, Nashville, TN

Abstract

Understanding workflow complexities is integral to achieving maximum effectiveness within clinical environments. Additionally, the coordination of patient care across multiple care providers has surfaced as an efficiency issue. Understanding workflow can help accommodate differences in user needs, which can improve HIT use and adoption. We offer an iterative, mixed methods, approach of workflow modeling to further the analysis and understanding of clinical workflow.

Introduction

Clinical care environments are complex systems supporting highly collaborative and dynamic conditions. Workflow evaluation has emerged as a method to analyze the complexity of clinical environments with relation to patient care coordination and identification of operational concerns. Quantitative workflow sources can provide some types of workflow-related data, but can also lead to correlation of events without understanding causation. Qualitative data provides insight into the interworkings of the clinical setting but presents challenges of scale, scope, and generalizability. We combined qualitative methods and data science approaches in iterative cycles to determine how researchers could build richer understanding of clinical workflow through a mixed methods approach.

Methods

We collected and analyzed both quantitative and qualitative data from three areas at the Vanderbilt Health One Hundred Oaks facility: the Vanderbilt Breast Center, an associated infusion clinic, and pharmacy. Qualitative data were collected through observation over more than 27 hours, divided across the three areas. During observations, free text notes about workflow were recorded. Resulting notes were coded and analyzed for common themes. Quantitative data were collected from Vanderbilt’s electronic outpatient whiteboard. The data set was assessed to identify and address incomplete cases and other data quality issues. Quantitative data were processed through timeline visualization tools created using JavaScript and D3 to determine themes. Iterative analysis of combined qualitative and quantitative themes was conducted after each day of observations.

Results and Discussion

Quantitative data collected between April 2014 and May 2014 provided patient flow data for 5592 unique patients across the two clinics. Initial findings indicate the breast center has the highest level of patient flow with over 2000 unique patients visiting the clinic over the two-month period. Though patient throughput was high, the breast center had a low rate of miscommunication with only seven coded instances. The infusion clinic indicated similar results, noting only five coded instances of miscommunication in 816 patient visits. This low rate of miscommunication – defined as an instance in which additional clarification or a break in workflow due to a lack of communication – may be related to the clinic’s high utilization of the electronic whiteboard. Patients spent the longest amount of time in infusion rooms, occupying the room for an average of 2 hours and 35 minutes per visit. This length of time spent in the infusion room is likely due to the time required to receive an infusion. However, upon arriving in the infusion room, an average of 29 minutes and 30 seconds elapsed before the infusion began. This additional wait time, while outside of the traditional waiting room, offers significant opportunity for efficiency improvements.

Conclusion

Our iterative mixed methods approach allowed us to provide a context to our quantitative data by understanding the inner workings of the clinical areas. Though data from the electronic outpatient whiteboard contributed to our unique understanding of the patient flow, data from employee time clock software, registration software, and pharmacy software could help to provide additional workflow metrics. We eventually envision our visualization tools being implemented into Vanderbilt Health’s electronic health record system to provide healthcare team members and clinic managers with a better understanding of the workflow in different clinics.
Using the Consolidated Framework for Implementation Research (CFIR) to Evaluate EHR Population Health Management Tools
Christina L. Stephan, MD PhD, Lori L. Popejoy PhD APRN GCNS-BC FAAN, David R. Mehr, MD, Esmaeel Rahmani, MD MSHI, Katie Wilkinson, MA, Eduardo J. Simoes, MD MSc DLSHTM MPH
1University of Missouri, Columbia, Missouri; 2Tiger Institute, Columbia, Missouri

Introduction
How electronic health record (EHR) innovation is implemented in clinical practice is influenced by the contextual environment. The Consolidated Framework for Implementation Research (CFIR) provides a comprehensive framework for analyzing an implementation process. We examined one component of a multi-faceted intervention to improve chronic disease care: an EHR-based provider panel dashboard, which shows performance on quality measures for a provider’s panel of patients. The objective of the study is to describe the use of the CFIR to analyze provider focus-group feedback regarding the implementation of the dashboard.

Methods
We conducted two focus groups to obtain information about barriers and facilitators that influenced physician adoption of the dashboard after the implementation. Focus groups of 10 and 6 physicians were conducted, recorded, and transcribed. The 39 elements in the CFIR were used to structure analysis of contextual barriers and facilitators to adoption of the dashboard. Results were used to describe opportunities for improved implementation.

Results
All of the focus group comments fit in the CFIR structure. Participants reported that the dashboard implementation was suboptimal. Three opportunities for improvement were identified: 1) Increasing provider engagement and communication early in the development and implementation process; 2) Increasing leadership engagement at the practice level to address work flow changes and clinical integration of new tools and practices; 3) Formalizing mechanisms for efficiently obtaining iterative feedback from clinical and administrative stakeholders to improve effectiveness of implementation efforts.

Discussion
Use of the CFIR has not yet been well documented in the informatics literature. The CFIR complements the established informatics socio-technical evaluation framework. To efficiently implement new tools or innovations, it is essential to understand the contextual factors that affect the implementation process and influence adoption. Use of the framework can also help stakeholders and investigators consider potential barriers that might be addressed prior to implementation. By systematizing the identification of barriers and facilitators, the comprehensive framework for implementation research enables a planning process which can accelerate adoption of innovations.

Conclusions
The CFIR provides a useful framework for understanding intervention implementation and opportunities for improving implementation processes. In this example of implementation of an EHR-based provider panel dashboard, issues of engagement, leadership, and feedback were identified as particularly important.

Matrix Completion Methods and Imputation for EMR-Based Prediction.

Erika Strandberg, MS\textsuperscript{1}, Mohsen Bayati, PhD\textsuperscript{2}

1. Stanford University Biomedical Informatics Training Program. 2. Stanford University Graduate School of Business.

Background
The availability of electronic medical records (EMRs) has allowed for the use of a large amount of clinical data for predicting healthcare outcomes; however, the high proportion of missing entries can make predictions and risk assessment difficult. Few studies have compared methodology for missing data completion with the objective of optimal predictive performance; even fewer studies have looked at imputing missing values in medical data with high amounts of incompleteness. In particular, lab results could be informative in determining patient health status; however, due to cost limitations, availability, risk and appropriateness, most labs are not performed on all patients. As such, only frequently performed labs are typically used in predictive modeling. In these situations, imputing lab results could be useful because (1) there might be a rarely performed test or combination of tests that is informative, (2) signal in repeated lab tests could be useful but not all patients have labs measured at the same intervals or (3) lab tests requested could be indicative of differential diagnosis so the act of performing or not performing a lab test could rule out other conditions. Since laboratory tests are typically performed when a practitioner suspects a certain diagnosis, missing values are not missing at random.

We compare the performance of existing data completion and imputation methods parameterized for predictive performance to novel imputation methods using both simulated data and real EMR data with hospital-associated conditions and mortality.

Methods
Simulated data was obtained by sampling random (patient, lab) pairs where the marginal distribution of labs matched the empirical distribution of labs from a large urban hospital’s EMR. Response variables determined by logistic regression on a random subset of lab results. Lab results were taken from the first day of admission to the ICU from the MIMIC II ICU database\textsuperscript{1}. The outcomes of interest were hospital-associated venous thromboembolism and mortality.

We imputed missing values using mean and k-nearest neighbors (kNN) imputation. We also used SoftImpute, a matrix completion method successful on the Netflix data set\textsuperscript{2}. Finally, we implemented novel aggregated multiple imputation method (MI) and a feature selection SoftImpute (FSSI), which performs feature selection prior to imputing using SoftImpute. Parameters were chosen through 10-fold cross validation to maximize area under the receiver operator characteristic curve (AUC) on a training set. Logistic regression with a lasso penalty was used to perform feature selection and classification and overall performance was assessed on held-out test sets.

Results
SoftImpute, FSSI and kNN all performed well for the different feature sets and classification tasks assessed. MI did not exhibit consistent performance. There was no clear best performer over all classification tasks; however, when the number of patients is high, kNN is not computationally tractable.

Conclusion
Results from this study indicated that the choice to impute is a good one; however, the best method to use may not be the same for all tasks. FSSI holds much promise due to its speed and performance.

Clinical Efficacy of Virtual Reality Rehabilitation Intervention for Patients with Low-back Pain: A Randomized Controlled Trial

Wu-Chen Su, MS1, Shih-Ching Yeh, PhD2,3, Si-Huei Lee, MD4, Hsiang-Chun Huang, MS3
1Chang Gung University, Taoyuan, Taiwan; 2Sun Yat-sen University, Guangzhou, P.R. China; 3National Central University, Taoyuan, Taiwan; 4Taipei Veterans General Hospital, Taipei, Taiwan

Introduction
Given that eighty percent of all people may have experienced low back pain (LBP) during their lifetime1 this health condition is a very common globally. Furthermore, LBP rehabilitation requires a considerably long commitment of time which in turn may cause patients to lack motivation to finish their entire course of treatment. As a result, LBP poses a substantial impact on society (e.g., increased medication cost). Recently, entertaining virtual reality-based systems (e.g., Wii Fit Yoga) have been used to encourage patients to complete their LBP rehabilitation tasks in an effective way2. However, these commercial exercise programs do not offer the capacity for patients to incorporate learning patterns into daily activities to ease cumulative low back loads in their daily lives and to prevent the recurrence of LBP. Therefore, these limitations merited the development of a previously proposed VR-based approach3 that tracks and measures patients’ movements during rehabilitation treatment in real time, provides immediate visual and auditory feedback to users, and allows physiotherapists use statistical information tracked and analyzed for treatment supports (Figure 1). In this study, the authors further evaluate the undertaking of patients’ rehabilitation intervention through a randomized controlled trial to examine the difference in efficacy between the proposed approach and usual LBP care.

Methods
Forty patients were recruited and randomly assigned into either an experiment group (EG) or a control group (CG). The difference of duration of pain (mean ± SD months) between groups was not significant (EG: 12.3±9.5 months; CG: 15.7±8.7 months; p>0.05). Physical therapies were provided for both groups firstly (e.g., hot pack). Subsequently, the EG used the proposed VR-based system as a therapeutic medium, and the CG was treated using the usual LBP exercise programs with health education. The rehabilitation sessions were performed 2-3 times a week for 4-6 weeks, and each session was 60 minutes. Patients answered survey questionnaires before and after the interventions relating the scale of their pain intensity (0-10), the degree of unpleasantness (0-10)4 and the level of disability (0-100)4 in their daily life. The Mann-Whitney U-test was used for statistical analysis (significance level=0.05).

Results
The EG demonstrated significant improvement (p<0.05) via alleviation of pain intensity (5.1±2.6 to 1.1±0.9) and unpleasantness (4.1±1.6 to 1.4±1.2) compared to the CG (pain intensity: 5.3±2.3 to 4.3±1.2; unpleasantness: 4.3±1.2 to 3.3±2.2) while performing general daily life activities (e.g., walking, sitting, etc.). Additionally, the average pain intensity scores and mean unpleasantness scores at baseline were 8.1±1.6 and 9.1±0.5 for the EG, and 8.3±3.1 and 8.3±1.1 for the CG during the period of exercise. VR-based treatments yielded significant reductions in pain intensity and unpleasantness (p<0.05) at the end of the study, with scores of 2.1±1.6 and 1.4±1.2 for the EG, and 5.6±3.2 and 4.3±3.1 for the CG. In addition, the disability impact of LBP on the participants’ daily life of the EG decreased significantly (79.2±11.6 to 21.1±9.6) compared to that of the CG (78±13.1 to 53.5±11.6) after treatments (p<0.05).

Conclusions
The experimental results demonstrate that the patients of the EG who received the treatments utilizing the VR-based therapies have better physical and mental health improvements (e.g., sleeping, walking, etc.) than the patients of the CG receiving the usual care. Thus, the physiotherapists suggest this approach may effectively reduce the burden of LBP patients and can be used to re-align daily life behaviors to prevent recurrence of LBP. In addition, the functionality of this system can be extended to provide tele-rehabilitation services to the general public in the future.

Comparison of Patient Portal Usage between Employees and Non-Employees

Lina M. Sulieman1, Dara L. Eckerle Mize, MD1,2, Daniel Fabbri, PhD1,3, S. Trent Rosenbloom MD MPH1

Department of Biomedical Informatics, 2 Division of Diabetes, Endocrinology & Metabolism, Department of Computer Science; Vanderbilt University School of Medicine, Nashville, TN

Introduction

Vanderbilt University Medical Center (VUMC) policies encourage employees with job-related electronic health record (EHR) access to review their own record. We hypothesized that with easy access to their own EHR, employees would be less likely to use the tethered patient portal. We compared patient portal usage by employee and non-employee patients. Identified variations in patient portal usage and patterns will guide the design of new functionalities in the patient portal and policies around its use.

Methods

VUMC is a private, non-profit academic medical center in Nashville, Tennessee that has in place a locally developed EHR and Patient Portal. Core portal functions include secure messaging, access to some EHR data, appointment scheduling and bill management. Subjects included all VUMC employee and non-employee patients who accessed their portal account between August 2013 and September 2014. We obtained data from the Vanderbilt Research Database (RD), a database of clinical and related data derived from VUMC’s clinical systems. We collected information describing the frequency and types of actions users took while viewing their patient portal.

Results

During the study period, 17,917 employees accessed the EHR. A total of 12,044 (67%) of those employees logged into their own portal account. There were 95,808 portal users, 87% are non-employee patients. Individuals in both groups accessed their account a mean 10 and a median 5 times over the study period. The top ten most commonly performed actions were the same for employee and non-employee patients (Figure 1). Figure 2 shows that a greater percentage of employee versus non-employee patients used portal messaging. The two groups equally used functions to view EHR data such as lab results, radiology reports, visit summaries and problem lists.

Conclusion

Functionalities related to secure messaging are the most commonly used among both user groups. A greater percentage of employee versus non-employee patients use the secure messaging functionality of the patient portal to communicate with their provider. This may reflect greater awareness of the tool. Use of other patient portal functions did not differ between the groups. Analysis of how employees use job-related access to view their own EHR may guide the development of new tools for the patient portal.
Personal Health Information Management Strategies:
Experiences of Patients in the US and China

Si Sun, MS, Nicholas J. Belkin, PhD
Rutgers University, New Brunswick, NJ 08901

Background
Harnessing personal health information has become increasingly important for people living with chronic conditions. Research has found that health information can help patients improve their health care outcomes by enhancing motivations and help with problem solving and interpersonal relationship management. To effectively use health information, many patients developed information management strategies that are continuously improved through trial and error. Understanding these strategies can provide important guidance to the development of supporting technologies.

In this study, we explore the personal health information management (PHIM) strategies of people living with diabetes mellitus. We examine how these strategies differ between people from two distinct social contexts and living with different health conditions (i.e., type 1 or type 2 diabetes). Understanding the PHIM strategies with these differences in mind can provide insight into the translation of health care interventions and the adoption of health information technologies across contexts.

Methods
In this study, we conduct semi-structured one-on-one interviews with 60 diabetes patients (30 from the US and 30 from China). Both type 1 and type 2 diabetes patients are included. All participants are recruited through snowball sampling. The first author recruit the first few participants from her social network and ask the exiting participants to introduce more patients. Other recruiting methods such as distributing advertisements at community centers, hospitals, online health communities, and through email listservs did not successfully recruit participants. To address the issue of sampling bias posed by snowball sampling, we will conduct a survey with a larger sample size, as part of a larger study. Participants from the US are mainly recruited in the New York City area, while those from China are all affiliated with a large research university in southern China. Long distance interviews in the US are carried out over Skype or the telephone. Interviews in China are all conducted face-to-face. We also collaborate with participants to perform photo-documentation. After the first interview, the researcher and the participants collaborate to take photographs depicting the PHIM strategies.

So far, we have completed the interviews and photo-documentation with all 30 (one with type 1 and 29 with type 2) participants in China and 23 (twenty with type 1 and 3 with type 2) in the US. The poster will present a collection of PHIM strategies from 60 participants. We will report these different strategies in relation to participants’ health condition, social contexts, age, sex and occupation.

Preliminary Results
Patients maintain a wide variety of PHIM strategies, some are so ingrained in their daily routines that they become invisible to patients. Some examples of the strategies we identified so far include: (a) Extensive recording and integration strategy: Some patients keep an extensive record health information and integrate it across information items to extract theories about their condition and take actions accordingly. (b) Location-based integration strategy: Many patients keep all diabetes-related information and information management tools at a single location (e.g., a box) and always go to that location when performing self-management activities. (c) Location-based redundancy strategy: Patients may also utilize a distributed information system comprised of synchronized information technologies and duplicated documents and items for reminder and fail-safe purposes. (d) Leadership responsibility strategy: Several patients assumed leadership roles in patient support groups and relevant health care organizations, and have become information gatekeepers. (e) Collaborated improvement strategy: Some patients share their information with a network of family and friends who provide constant feedback to their performance and assist with regimen adjustments.

Data-driven knowledge base evaluation: Translating an adult CDS tool for use in pediatric care

Katherine A. Sward, PhD RN¹, Christopher J Newth, MD FRCPC², Robinder G. Khemani, MD MsCI², J. Michael Dean, MD MBA¹

¹University of Utah, Salt Lake City, UT; ²Children’s Hospital Los Angeles and University of Southern California Keck School of Medicine, Los Angeles, CA

Introduction
Clinical decision support (CDS) tools link evidence and clinical expertise with patient-specific information; e.g., to make a treatment recommendation that is evidence-based but tailored to the patient state¹. CDS recommendations can only affect clinical care if the recommendations are acceptable to clinicians². Ensuring recommendations are appropriate for the context of care is necessary for clinical acceptance. Knowledge base (KB) maintenance, localization, and adaptation to new use contexts can be an especially challenging aspect of CDS development¹,³,⁴.

Problem
KB maintenance is complex and can require prohibitive amounts of clinical expert and knowledge developer time¹,⁵.

Approach
A CDS tool for ventilator management in pediatric intensive care unit (ICU) ARDS/Acute Lung Injury patients was adapted from a tool used in adult ICUs, based on input from clinical experts in the PALISI and CPCCRN networks. The KB was implemented using production rules; with 2829 rules and 56409 lines of code. We used PICU clinical data to evaluate the extent to which “usual care” actions corresponded with what the protocol would have recommended for the same patient state; using heat maps and other data visualization and analytic approaches to assess correspondence. Emulated CDS tool interactions further explored focused issues with clinical experts. We qualitatively evaluated alignment with the current “parent” ICU protocol and with the emerging guidelines from the Pediatric Acute Lung Injury Consensus Conference (PALICC) group.

FINDINGS: PICU data suggested usual care results in only about 50% conformity to known best practices, with wide variability; so there is substantial opportunity to improve lung protective ventilator practices². The pediatric CDS tool remained qualitatively aligned with the parent protocol and with PALICC guidelines; there were small changes to thresholds and the magnitude of changes but the basic approach was maintained. We identified sets of rules in which

1. Clinical practice already aligns with protocol recommendations. These rules do not need modification.
2. The patient state was seldom observed in the clinical data. These rules were evaluated against literature to ensure that they align with best known evidence and current guidelines.
3. The protocol recommendations do not align with current clinical practices. These rules need to be evaluated by clinical experts. This represented less than 20% of the rules.

Conclusion
KB maintenance and adaptation to new contexts are complex and time consuming tasks but are necessary if users are to accept CDS recommendations. Using clinical data to inform KB maintenance efforts aligns with the vision of the Learning Health System. While knowledge maintenance remains a complex task, clinical data and analytics can usefully contribute to focusing knowledge engineering efforts on rule subsets that might need modification.

Understanding Why Providers Override Computerized Medication Alerts in the Inpatient and Outpatient Setting

Michael Swerdloff BS1, Diane L Seger RPh1,2, Mary G Amato, PharmD MPH1,6, Nivethietha Maniam BS1, Olivia Dalleur, MPharm PhD1,4,5, Julie M Fisko BS2, Quoa Liang Her PharmD MS1, Sarah P. Slight MPharm, PhD PGDip1,3, Patrick E. Beeler MD1,9, Tewodros Eguale MD PhD1,6,7, Patricia C Dykes PhD MA RN 1,9, David W Bates, MD MSc1,9

1Brigham and Women's Hospital, Boston, MA, USA; 2Partners Healthcare, Wellesley, Boston, MA, USA; 3School of Medicines, Pharmacy and Health, Durham University, Durham, UK; 4Louvain Drug Research Institute, Universite catholique de Louvain (UCL), Belgium; 5Cliniques universitaires Saint-Luc (UCL), Brussels, Belgium; 6MCPHS University, Boston, MA; 7McGill University, Montreal, Quebec, Canada; 8Massachusetts General Hospital, Boston, MA, USA; 9Harvard Medical School, Boston, MA, USA.

Abstract: Computerized decision support (CDS) alerts are often overridden in the inpatient and outpatient setting. We evaluated both inpatient and outpatient providers focusing on their behavior and practice when overriding these alerts. While providers in the inpatient and outpatient setting were grateful for alerts and felt they contribute to patient safety, inpatient clinicians felt that CDS alerts could be more effective and efficient since they saw their patients more frequently and were likely to experience alert fatigue.

Introduction: Application of computerized decision support (CDS) alert functionality has been variable between inpatient and outpatient providers. We continue to observe a high level of alert overrides. While many overrides are justified clinically, some are not. It is important to reach out to those providers who are not prescribing optimally to understand their reasons for overriding alerts, and whether these reasons differed between the inpatient and ambulatory setting.

Methods: We evaluated all Level 2 alert overrides between January 2009 and December 2011. We then limited our sample to providers who received 20 or more alerts. Of the 2,495 providers eligible for the study, 1,770 inpatient and 725 ambulatory, we targeted those with a high inappropriate alert override rate. Research pharmacists conducted academic detailing sessions tailored to each provider’s override alert profile. A robust and complete analysis of the data was carried out and prevalent concepts related to alert functionality and specific prescribing behavior identified.

Results: We conducted 43 total academic detailing sessions, 34 with outpatient and 9 with inpatient providers. Many inpatient providers felt that alerts reminding them to monitor their patients were extraneous, and ignored these warnings as they were seeing their patients regularly. They recommend the option to disable alerts consistently overridden and ignored. In the outpatient setting, providers found the clinical relevance of the alerts could be improved with provision of recent laboratory values, and the ability to order additional tests directly from the alert.

Conclusion: Insights identified through academic detailing sessions included that alert fatigue existed for warnings deemed irrelevant, and frustration that repetitive alerts could not be disabled. Inpatient providers were more frustrated than outpatient clinicians when prompted to monitor their patients. The alerts were appreciated when the provider first saw the patient, however subsequent alerting was seen as frustrating and time consuming. Inpatient clinicians would like to see repetitive alerts less frequently. By incorporating provider preferences, and considering the increased attention patients receive in a hospital; providers felt that CDS alerts would be less likely to be overridden and more likely to lead to providing more effective, efficient care.

Leveraging a Clinical Data Warehouse to improve the quality of data in the French DRG-based system (PMSI)

Emmanuelle Sylvestre, MD, MSc, Christine Riou, MD, Guillaume Bouzillé, MD, Marc Cuggia, MD, PhD

1INSERM, U1099, Rennes, F-35000, France; 2Université de Rennes 1, LTSI, Rennes, F-35000, France; 3CHU Rennes, Centre D’Investigation Clinique, Unité Fouille de Données, Rennes, F-35000, France; 4CHU Rennes, Département D’Information Médicale, Rennes, F-35000, France

Introduction
Over the past few years, clinical data warehouses have been essentially used and developed for research purposes. However, they are a great source of integrated data and can cater to different needs, especially in health economics. Since they are exhaustive and are able to manage heterogeneous data, clinical data warehouses can meet the requirements of the French DRG-based system (PMSI): efficacy (especially regarding the time spent coding) and efficiency (with an emphasis on exhaustiveness). The aim of this study is to develop a methodology to improve coding using drug prescription data from the hospital’s clinical data warehouse.

Methods
A retrospective analysis was performed, using data from the hospital’s clinical data warehouse. All patients hospitalized between October and December 2014 in the otorhinolaryngology ward of Rennes University Hospital, were included. This unit was chosen because surgical records do not necessarily evoke existing chronic diseases when the hospitalization is not related to those. Yet, these diseases are comorbidities often associated with drug prescriptions available in electronic health records but they are rarely mentioned in the surgical record and therefore, cannot be coded. The premise of this study is that it would be possible to infer these comorbidities from drug prescriptions and hence encode them despite their absence in the surgical record.

First, drug prescriptions from the hospital information system were associated with their Marketing Authorizations (MA), using a French drug knowledge database named Thériaque. Thus, each drug was matched with one or several disease(s) and their corresponding ICD 10 codes. This list was then crossed with another one called CMA (Complications et Morbidités Associées), which is a national list of complications and morbidities (and their ICD codes) that significantly increase the cost of a hospital stay. This way, each drug prescription associated with one or several potential comorbidities was identified. Hospitalization data was finally processed: DRG ICD-10 codes from patients with at least one drug prescription were compared to those from the enriched drug database. In case of a missing code, the potential comorbidity was inferred using text mining techniques on electronic medical records (EMR) to find a written proof of the diagnosis in the clinical data warehouse.

Results
39 400 UCD codes were associated with at least one of the 4878 comorbidities from the CMA list. On the 122 hospital stays with at least a drug prescription for this period, 75.4% had at least one drug prescription with no corresponding ICD code. Information on the missing diagnoses with the help of the clinical data warehouse was found in 44.6% of the hospital stays. The three main reasons why information was not found were: the diagnosis wasn’t written but implied, there wasn’t any other proof than the medication on the diagnosis or the prescriptions suggested a symptom that was part of a syndrome which was already coded in the original DRG. The majority of the 58 detected comorbidities (43.1%) were chronic cardiovascular diseases that were not specifically treated (except for the medication) during the hospital stay.

Conclusion
The clinical data warehouse helped retrieve missing DRG codes and therefore improve the exhaustiveness of coded data. Some retrieved codes were part of the CMA list and therefore changed the cost of the hospital stay. This method is generalizable to different hospital areas and need to be tested on a bigger sample.

Lost in the Fog: Information Needs in the Care of Patients with Delirium

Teresa Taft1,2, Scott D. Nelson PharmD, MS1,2, Stacey Slager MS1,2, Charlene R. Weir, RN, PhD, FACMI1,2

1Veterans Affairs Medical Center, Salt Lake City, UT; 2Department of Biomedical Informatics, University of Utah, Salt Lake City, UT

Problem: Delirium is the most common complication of hospitalized adults over age 651. It occurs in 14-56% of hospitalized patients, depending on the associated conditions2-4. Delirium is associated with increased complications, longer hospital stays, increased rates of institutionalization, and increased mortality5. The annual economic burden in the United States has been estimated as high as $164 billion5-6. Identification of delirium is imperative because it points to a serious health problem requiring very different treatment from conditions with similar appearance7. However, delirium is undiagnosed in 1/2 of cases8. Understanding physician’s decision-making processes in addressing diagnostic dilemmas for delirium is crucial to the design of effective decision support.

Methods: Critical Incident interviews were conducted. Nine internal medicine physicians (5 of whom are experienced geriatricians) at a single location were asked to report a complex case in diagnosing a patient over age 65 with acute mental status changes (AMS). Decision points were identified and decision processes and information needs were elicited by guided questioning. The interviews were audio recorded and transcribed and three authors conducted iterative contextual analysis, using qualitative software.

Results: Preliminary analysis has focused on causes of uncertainty and strategies that physicians use to manage this uncertainty in the delirium workup process. Three main thematic areas associated with uncertainty emerged: (1) baseline mental status data is often unavailable or is hidden, (2) attribution of AMS can be multifactorial & ambiguous, and (3) available information sometimes lacks credibility. Five strategies for managing uncertainty and one “nonuse” also emerged: (1) expending extensive time and effort obtaining records and/or searching in the medical record for the patient's baseline mental status; (2) tracking down people who personally know the patient for direct questioning; (3) ruling out conditions through testing or treatment; (4) making assumptions of dementia when baseline mental status information is not available or is not trusted; and (5) requesting a consult. Despite knowledge of their existence, physicians made no use of delirium decision support tools including: anticholinergic load calculators, lists of medications to avoid in the elderly, or specific delirium screening tools.

Conclusions: There is a need for prior functional/mental status information of healthy patients in the electronic medical record to support delirium workup. Improvements to search mechanisms are needed to improve efficiency in locating mental status information in the medical record. Video and pictures of the patient, such as those typically found on social web sites may be especially useful to physicians in determining a patient’s baseline mental status. Access to medical records from outside health institutions continues to be needed. In addition, the design and accessibility of delirium decision support tools must be addressed to support use within physician workflow.

Developing an Enhanced Electronic Referral Management System
Amanda V. Taube¹, Pamela M. Neri, MS², David Kiernan³, Inna Natanel², Harley Ramelson, MD¹,³
¹Clinical and Quality Analysis, Partners HealthCare, Wellesley, MA, United States; ²Partners Healthcare Systems, Inc., Wellesley, MA, United States; ³Internal Medicine, Brigham and Women's Hospital, Boston, MA, United States.

Introduction: While referrals done in an ambulatory environment require the successful completion of multiple independent steps, there is, not infrequently, a breakdown in at least one of the referral management steps that can lead to patient safety and liability issues.¹ The objective of this innovation program is to provide an enhanced electronic referral management module in an ambulatory EHR that would enable practices to meet the requirements for best practice steps for referral management and to observe the effects of electronic referral management on practice workflows.

Methods: An enhanced electronic referral management module was developed in an ambulatory EHR used by a large integrated delivery system in the northeast. The module includes the ability to create, transmit and track referrals throughout the entire referral cycle. Functions in this module include the ability to refer to a practice in addition to an individual specialist, to search a directory of specialists, to maintain a favorite list of specialists and practices, to acknowledge the consult note, to document communications with the patient, to document that the patient has been notified of the consult results and follow-up recommendations and to document the closing of the referral. Advanced system functions include automatically identifying the appointment date by interfacing with scheduling systems, automatically linking the consultant’s note to the referral by connecting with the EHR’s notes module, and using a rule-based approach to identify when a referral is overdue. Enhanced workflow features include the ability to support the staff creating the electronic referral and sending to the provider for authorization or, alternatively, the provider creating the referral and sending to the staff to complete the administrative functions. The module also provides a referral queue for all of the practice’s referrals or a queue focusing only on a particular provider’s referrals. In both of these queues, users can quickly identify what state a particular referral is in and whether it is overdue. The module allows communication with the specialist by providing electronic communication via secure messaging that includes the reason for the referral as well as the ability to include the referring provider’s visit note and the patient’s clinical record (in the form of a C-CDA document). The specialist’s view of the schedule includes an indication that the patient’s visit is a result of the referral with a one-click access to the information entered by the referring physician. Metrics that can be monitored include the percent of referrals that result in a completed specialist visit, the percent of completed specialist visits for which the specialist’s note was electronically acknowledged by the referring provider or staff and 1.2% had documentation that the patient was notified of the consult results and follow-up recommendations.

Results: This study enrolled nine ambulatory primary care practices affiliated with an integrated delivery system in the Northeast. Approximately 80 practice staff members, including physicians, medical assistants, nurses, and administrative staff typically involved in the referral process were recruited across these practices to use the module. After 5 months of use, a total of 2876 referrals were initiated, of which 2127 were closed. Of the closed referrals, 23.8% had a completed specialist visit with a note documented in the EHR, 25.2% of the specialist’s notes were electronically acknowledged by the referring provider or staff and 1.2% had documentation that the patient was notified of the consult results and follow-up recommendations.

Conclusion: A successful referral management program depends upon having the necessary technological tools to properly monitor referrals and identify when a breakdown on the process has occurred. Equally important are the workflow changes that need to be made in the practice in order to monitor the referral queues and intervene when necessary. We have shown that electronic referrals can be successfully created and tracked. Preliminary metrics demonstrate that there are a significant number of referrals that were closed without a specialist note documented in the EHR and that electronic coded documentation of communication with patients is not commonly performed. Additional resources and practice leadership will likely be necessary to address the issues raised by these metrics.

Mapping APACHE IV “Reason for Intensive Care Admission” Classification to SNOMED CT
Charat Thongprayoon, MD; Amelia K. Barwise, MB, BCh; Andrew M. Harrison, BS; Brian W. Pickering, MB, BCh; Vitaly Herasevich, MD, PhD
Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC) Mayo Clinic, Rochester, MN

Background: The APACHE IV classification is used to capture admission diagnostic information for calculation of mortality risk in the intensive care unit (ICU). The lack of structured and formal mapping of APACHE IV to standard classification systems, such as SNOMED CT, is a rate-limiting factor for data sharing, aggregation, and classification.1 However, SNOMED CT contains large amounts of information that is not pertinent for most clinical conditions in the ICU. The objective of this study was to build a linked terminology, based on SNOMED CT and APACHE IV, to reduce the complexity of SNOMED CT for linkage purposes, while enabling standardized data registration.

Methods: For the primary reason for ICU admission using the APACHE IV classification system, there are 119 divisions with 422 diagnostic categories. Each reason for ICU admission is classified as non-operative or post-operative, body system or a transplant or trauma-related category, and finally by diagnosis. For mapping purposes, SNOWMED CT Concept Codes were reviewed by a single trained investigator (CT) to identify either a single or post-coordinated SNOWMED Concept match for each diagnostic category of APACHE IV classification using Snow Owl version 2.0.0. Each matched concept-category pair was assessed by categorizing each concept-category pair as a complete match, partial match, or non-match.

Results: Out of 422 diagnostic categories, SNOMED CT provided a complete match with APACHE IV classification for 356 (84%) patients, partial match for 58 (14%), and non-match for 8 (2%) (Table 1).

Table 1: Result of mapping between APACHE IV classification and SNOMED CT Concept Codes

Platform for Engaging Everyone Responsibly (PEER) Validation Study Plan

Sheri R. Tibbs, MPH1, Cynthia Kluchar, MS,1 Sharon F. Terry, MA,2 Eric L. Eisenstein, DBA1
1Duke Clinical Research Institute, Durham, NC, USA; 2PXE International, Genetic Alliance, Washington, DC

Introduction
Genetic Alliance (GA) is a network of more than 1000 disease advocacy organizations (DAOs) seeking to advance biomedical research. GA developed the Platform for Engaging Everyone Responsibly (PEER) tool as a web-based application for DAO participants to share clinical information within a trusted environment via access-permission rules. PEER data are aggregated, filtered through privacy directives, and made available to qualified stakeholders.

On January 14, 2015, The U.S. Food and Drug Administration (FDA) approved the Maestro Rechargeable System for certain obese adults. This is the first time patient preference data were used in regulatory decision making.1 PEER is a potential tool for patient preference data collection; however, it requires validation for this use.

Methods
We designed an evaluation study using the UFuRT analysis methodology of Zhang and Butler as adapted to the clinical research data management (CRDM) domain by Nahm and Zhang.2,3 UFuRT is a work-centered design methodology. We used two UFuRT elements (User and Function) to identify PEER user types and their complete functionality set. Each function was standardized as an element in the CRDM domain ontology. We then mapped each standard function to one or more of the PCORI methodology standards to determine which recommended standards should be implemented to ensure scientifically valid patient-centered outcomes research.4

Results
We identified nine PEER systems user types characterized by their clinical research responsibilities and level of technical and research expertise. These included data providers (participants, genetic testing labs / genetic sequencing tool companies and health care providers), application developers (disease advocacy organizations and system administrators), organizations seeking to learn / teach others about a specific medical condition (community organizations, professional societies), as well as interested researchers (standalone and research study sponsors).

We next related each PEER system user type to one of 55 functions from the CRDM ontology developed by Nahm and Zhang.2 We found differences in functional requirements and use intensity between user types. This mapping provided a high-level set of user-derived functional requirements. Lastly, we mapped the previously identified PEER system CRDM functions to elements of the PCORI methodology standards. This second mapping helped us identify the standards that should be adopted to ensure valid results.

Conclusion
We used the UFuRT analysis methodology and PCORI methodology standards to identify PEER system user types, general functional requirements and candidate evaluation methods. While these methods provided an integrated approach, greater detail will be required to create a final evaluation plan and study protocol. Additional research is needed to extend the UFuRT and PCORI methodologies for this use case.

A Systems-Based Framework for Informatics Workforce Development to Support Health System Transformation
Herman Tolentino, MD, Laura Franzke, PhD, MPH, Sridhar Papagari Sangareddy, MS
Division of Scientific Education and Professional Development, Centers for Disease Control and Prevention

Introduction

The United States lags behind certain high-income countries in health outcome versus spending per capita [1]. Intersectoral collaborations are needed for participants in the health system to achieve a collective impact for improving health outcomes among both persons and populations. A competent, informatics-savvy, and boundary-spanning workforce is essential to health system transformation to improve population health. To deliver this intended outcome, the authors developed a systems-based framework to support strategic interventions at experiential learning ecosystem leverage points.

Methods

A triaxial framework was developed to represent this experiential learning ecosystem (Figure 1), which has the following components: (1) work and effect settings where collaborative health system transformation and service-learning activities occur; (2) skill development levels [2]; and (3) workforce pipeline stages of professional development. An incremental approach was used to iteratively test different interventions at these leverage points. The continuum of professional development is aided by a semiotic cycle of knowledge generation and application [3], whereby knowledge captured from applied activities in the work or effect settings are organized coherently to further refine and improve interventions.

Results

Multiple interventions have been designed and are at various stages of implementation at leverage points in this experiential learning ecosystem. The poster describes outcomes and effects of ongoing initiatives at these leverage points.

Conclusion

The triaxial framework helped the authors conceptualize and implement innovative interventions at leverage points in an experiential learning ecosystem. The incremental and iterative implementations of these interventions support the strategic delivery of integrated service-learning activities to improve population health.

Lack of Unique Healthcare Identifier in Healthcare Information Exchanges: A Field Study
Monica Chiariini Tremblay, Ph.D., Gloria J. Deckard, Ph.D., Peng Zhang

ABSTRACT: This work proposes a two-stage qualitative study on the impact on the lack of a Unique Healthcare Identifier (UHID) on interoperability of patient records and in successful Healthcare Information Exchanges (HIE). We begin by discussing problems introduced by the lack of a UHID: difficulty in correctly matching patient records which results in diminished ability to improve patient outcome through health information exchange. We describe the cases of unmatched records as an instantiation of Type I and Type II errors and examine the barriers to adopt UHID. We empirically study this phenomenon in two field studies conducted in the state of Florida. The research team is part of the evaluation team of the implementation of the HIE in the state of Florida, which gives us access to investigate the statewide HIE transactions; specifically the rates of non-matched and unfound searches. We collect both qualitative data through interviews and metrics related to the State of Florida HIE.

INTRODUCTION: US healthcare system is facing huge challenges. Many scholars, policy makers and practitioners believe that Healthcare Information Exchange (HIE) offers at least partial solution to the problem of interoperability and continuity of care. Despite the great potential benefits that HIE promises, the implementation of HIE is by and large marginally successful and many scholars try to identify barriers that might hinder the development of HIE.

UHID: Among many potential barriers of HIE, some scholars argue that the lack of a unique healthcare identifier (UHID) negatively impacts the development of HIE. If HIE is considered as an IS database infrastructure, it must follow the minimum principles of any good database design. Technically, the HIE database system lacks a primary key, or a unique healthcare identifier (UHID) for all patients. Lacking of a primary key greatly increases the difficulty of identifying a patient’s record, and increases the possibility of erroneous use of patient data in the system. The drawbacks of not having a UHID have been discussed in theoretical or experimental settings by scholars [1], but to date there are few, if any, studies that examine the impact of UHID on HIE in an empirical setting. To gain such insights, we propose a two-wave research project to fulfill such a purpose. By examining the interview data for the evaluation through the three year period, some insights are gained which serves as the foundation for the second round of focused research for UHID.

TYPE I AND TYPE II ERRORS: To exchange healthcare information, such as patients’ medical records, patients are from the lack of understanding of the contribution of UHID to HIE. Our proposed research gain better understanding of UHID and thus facilitate trust of the public and help the development of HIE. The research is comprised of two waves of data analysis. The first wave is based on the analysis of archival data of the Florida HIE evaluation [2] to gain initial understanding of how UHID impacts HIE. The second wave of the data collection of the study, projected to be completed between 2015 and 2016. Specifically, both qualitative data and quantitative data are to be collected to examine the potential UHID impacts on HIE. The goals of data collection is to gain insights of people’s opinions regarding the significance of UHID. PLU’s actual use, or the quantitative data, such as the query time, Type I and Type II errors, and consequences induced by these errors, will be collected and analyzed to quantify the actual loss of lacing UHID or potential gains of when UHID is in place.

CONCLUSION: Despite the great efficiency gains of UHID, the plan of implementation has encountered many oppositions. Many of the oppositions are from the lack of understanding of the contribution of UHID to HIE. Our proposed research gain better understanding of UHID and thus facilitate trust of the public and help the development of HIE.

Integrating an Externally Developed Clinical Decision Support (CDS) System with an Existing Electronic Health Record (EHR) System at VA

Samson W. Tu, MS¹,², Kaeli W. Yuen, BS¹, Connie Oshiro, PhD¹,
Susana B. Martins, MD, MS², Ignacio Valdes, MD, MS³, George Welch, MS³,
Paul Heidenreich, MD¹,², Mary K. Goldstein, MD, MS¹,²
¹VA Palo Alto Health Care System, Palo Alto, CA; ²Stanford University, Palo Alto, CA; ³Astronaut Contracting LLC, Houston, TX

Introduction: The VA electronic health record (EHR), Computerized Patient Record System (CPRS), has capability for CDS through its clinical reminders system; however, the built-in clinical reminders are not well designed for encoding complex patient care recommendations. We have previously developed a CDS system, known as ATHENA-CDS, that encodes complex clinical practice guideline recommendations, extracts data from VA’s patient data repository, and, when triggered by events in CPRS, displays in a standalone window guideline-based recommendations for the management of problems such as hypertension and chronic pain. In two experimental projects reported here, we developed mechanisms for a much tighter integration with CPRS and for the delivery of ATHENA-CDS recommendations within CPRS’s clinical reminder system.

Methods: In an initial prototyping project, we worked with Astronaut Contracting LLC to develop Point of Care (POC) software that can invoke ATHENA-CDS for hypertension, export data to it, and retrieve and format ATHENA-CDS recommendations as a dynamically generated CPRS reminder. In a second project, we updated an existing ATHENA-heart failure-knowledge base (ATHENA-HF-KB) to align it with the 2013 American College of Cardiology/American Heart Association guidelines for the management of heart failure and added the KB to the integrated CDS system. The system architecture includes (1) a data-extraction module that extracts clinical data of patients with next day appointments, updates the data and extracts the data of walk-in patients in real time, and converts the data in a format usable by the ATHENA-CDS system, (2) an ATHENA-CDS server that uses the patient data to compute CDS recommendations, (3) a monitoring module that interprets the CDS output to decide whether a patient has ‘reminder due’ or ‘reminder not due,’ and (4) a display module that, for patients with ‘reminder due,’ dynamically generates reminder dialogs and acts on the clinicians’ management decisions.

Results: We expanded and enhanced the knowledge encoded in ATHENA-HF KB to include a greater range of contraindications to our recommended therapies and more nuanced action choices to account for special cases. We implemented the prototype system of integrated heart failure and hypertension CDS within CPRS in a CPRS sandbox provided by the Veterans Health Administration Innovations Office. The prototype integrated system computes recommendations using an external server with encodings of complex guideline recommendations, but allows the VA clinician to interact with patient-specific advisories within VA’s existing reminder system workflow. These externally generated ‘dynamic reminders’ make use of the CPRS capability to include clickable buttons to take actions within CPRS and allow a user to access reference and educational materials through links in the CDS display. We tested the system with a collection of simulated patient encounters.

Discussion: Our work demonstrates how an externally developed CDS service for patients with complex management choices can be integrated in a legacy EHR not designed with such integration in mind. Unlike the earlier integration strategy, which displayed CDS recommendations in a standalone window, the current system embeds the CDS within CPRS’s existing reminder workflow and gives clinicians easy ways to enact guideline-recommended management changes. Aside from the extraction and transformation of data needed for the management of hypertension and heart failure, the architecture can be applied to other clinical areas. A limitation of the experiments reported here is that the CDS display, with the exception of actionable buttons, is confined to formatting available in the underlying EHR, in this case text whose formatting is not as rich as the standalone interface. This work highlights the desirability for an EHR system to facilitate integration with externally-developed CDS services by providing controlled access to patient data and by having mechanisms for interpreting and displaying such computed CDS.

Acknowledgments. The work was supported by a VHA Strategic Innovations Project, and by VA HSR&D grant RRP 12-447 (PI Goldstein). Views expressed are those of the authors and not necessarily those of the Department of Veterans Affairs or other affiliated institutions.
Smart Coach: A Problem-Solving Mobile App to Support Weight Loss Management

Bengisu Tulu, PhD1, Emmanuel Agu, PhD1, Stephenie Lemon, PhD2,
Jessica Oleski, MS2, Martinus Evans, MA2, Sherry Pagoto, PhD2
1Worcester Polytechnic Institute, Worcester, MA; 2University of Massachusetts Medical School, Worcester, MA

Introduction

Lifestyle interventions, while effective at reducing weight and diabetes risk, are intensive which makes widespread implementation difficult. Mobile technology may reduce intervention intensity while preserving outcomes by assisting in the delivery of behavioral strategies. However, the range of evidence-based strategies addressed by mobile apps on the current market is narrow.1,2 A key strategy missing across apps in both the market and research is problem solving, an essential component of behavioral weight loss interventions.3 We developed Smart Coach, a mobile app that implements problem solving strategies, to help patients during their weight loss journey by identify solutions to their weight loss problems. In this poster, we report on the usability study results.

Methods

We recruited 29 participants from the local Worcester community for requirements gathering and usability studies. All participants went through telephone screening for initial eligibility assessment followed by in-person screening visit that include consenting procedures, height/weight measurements, and an online survey (measures: demographics, distress tolerance, emotional eating, and emotion regulation). First 12 participants attended a 60-minute “think out loud protocol” where each participant verbalized their thoughts, actions, and feelings while they were using Smart Coach. Next, we conducted 4 focus groups where participants used Smart Coach for 15 minutes and explored its features. A total of 17 participants provided feedback on the Smart Coach user interface, system features, organization of the problem solving process, database of problems and solutions, and ease of use during these focus groups. All participants completed a System Usability Scale (SUS)4 survey at the end of their visits. Our sample was 79% female and 93% Caucasian. The average age of our sample was 49 and the average BMI was 35.

Results

Smart Coach is an avatar-facilitated, idiographic problem solving mobile app that processes information intelligently to help patients identify potential solutions to their weight loss problems. We identified a large set of problems and solutions based on our review of transcripts from 30 weight-loss problem solving session conducted by the investigators. Through an iterative process, we developed Smart Coach utilizing the input from talk through sessions. SUS scores during the development process ranged from 83 to 95. During the focus groups, we observed a wider range for SUS scores (32.5 to 100) with an average score of 79.7 indicating that the user groups were overall satisfied with the features and the content of the app. Most users reported that the app has a pleasant interface, simple and easy to use, and is very intuitive. Users also expressed interest in a social feature and that regularly updated information is important for continued use. However, integrating Smart Coach with their favorite wellness-tracking app was the key factor that would bring users back to using problem solving techniques more often.

Researcher Needs for a Patient-Centered Outcomes Research (PCOR) Data Infrastructure

Petry S. Ubri1, Prashila Dullabh, MD1, Tyne Alexander1, Alison Rein, MS2, Erin Holve, PhD, MPP, MPH2, Abigail Schachter2

1NORC at the University of Chicago, Bethesda, MD; 2AcademyHealth, Washington, D.C.

Research Objective

The Affordable Care Act established the Patient-Centered Outcomes Research Trust Fund (PCORTF), which provides the Office of the Secretary (OS) funding to enable data infrastructure for PCOR. Under the OS PCORTF work managed by the Assistant Secretary for Planning and Evaluation (ASPE), we reached out to research community representatives to gather feedback on key high-level functionalities and standards, policies, services, governance structures, and federal data needed to support a thriving PCOR data infrastructure.

Study Design

From March to April 2014, we conducted nineteen 60-minute semi-structured discussions with researchers, asking them to identify gaps and potential investment opportunities related to functionalities and components needed to enable PCOR data infrastructure. In May 2014, we held an in-person meeting with eleven of the researchers interviewed to identify gaps and priority areas in which further investment in PCOR data infrastructure are needed.

Principal Findings

- Participants called for greater linkages across Medicare and Medicaid data to enable researchers to gain a complete national perspective on patient care, outcomes, policies and services for collecting patient consent.
- Participants agreed that collection of patient-generated health data, including from mobile devices and other sources, is important but highlighted concerns with data provenance and accurate analysis and interpretation of the data.
- Regarding uses of PCOR data infrastructure, researchers’ opinions on the value of some specific investments to increase data capacity differ:
  - Some discouraged further investments in data registries, which they see as workarounds absent standards and interoperability. Others felt registry investments are essential due to data quality and aggregation issues.
  - Some participants emphasized the need for investing in flexible, adaptable common data models to facilitate data aggregation and analysis while others focused on the importance of standards for common data elements.
- Sustainability requires aligning incentives for providers and payers to build, utilize, and maintain PCOR data infrastructure. Participants noted a need for aligning standards and reporting requirements, promoting use of common infrastructure, integrating research processes into healthcare operations, and transitioning to public-private partnerships.
- Participants emphasized the need for feedback loops notifying providers and other data users of quality issues, and metadata standards describing data quality including data completeness, comprehensiveness, and validity. They also encouraged the standardized collection of clinical and claims data.

Conclusions

Researchers’ perspectives on the essential needs, improvements, and mechanisms to support the development and expansion of a PCOR data infrastructure are diverse; yet, there is agreement on the need for investments to address data quality issues, facilitate access to federal and private data assets, enable the collection and integration of patient-provided data, and promote sustainability of data infrastructure through needed standards and policies.

Implications for Policy, Delivery or Practice

By identifying existing gaps and potential opportunities around researcher needs for a PCOR data infrastructure, we highlight potential research and investment opportunities that can improve current processes for data capture, storage, and use of health data for the continuum of activities ranging from healthcare operations through research, including CER and PCOR.
Hospital Participation in Meaningful Use and Rehospitalization of Medicare Beneficiaries

Mark Aaron Unruh, PhD¹, Joshua R. Vest, PhD¹, Hye-Young Jung, PhD¹, and Rainu Kaushal, MD, MPH¹,²,³,⁴

¹Department of Healthcare Policy & Research, Weill Cornell Medical College, New York, NY
²Department of Medicine, Weill Cornell Medical College, New York, NY
³Department of Pediatrics, Weill Cornell Medical College, New York, NY
⁴NewYork-Presbyterian Hospital, New York, NY

Abstract: Nearly 20% of hospitalized Medicare beneficiaries are readmitted within 30 days. Hospitals’ use of electronic health records (EHRs) may reduce readmission rates. Over 90% of non-federal hospitals now possess Meaningful Use certified EHRs. We compared the odds of rehospitalization before and after Meaningful Use for Medicare discharges from Florida hospitals. Compared to the control group, hospital participation in Meaningful Use was associated with 3% lower odds of rehospitalization (Odds Ratio: 0.970, 95% Confidence Interval: 0.949-0.997).

Introduction: The nation has committed nearly $30 billion for provider adoption of interoperable electronic health records (EHRs) through the Meaningful Use program.¹ Over 90% of non-federal hospitals now possess EHRs certified for Meaningful Use.² However, little is known about the effect of hospitals’ participation in the program on the quality and value of care. We examined the impact of hospitals’ participation in Meaningful Use on rehospitalization of Medicare beneficiaries. Rehospitalization among Medicare beneficiaries is frequent, poses risks for patients, and costs the federal program over $17 billion annually.³ Hospital adoption of interoperable EHRs may reduce rates of rehospitalization by improving access to patient information and enhancing the coordination of care. We provide early evidence of the impact of participation in Meaningful Use on 30-day readmissions from hospitals in Florida.

Methods: We linked State Inpatient Databases from the Healthcare Cost and Utilization Project with the American Hospital Association’s Health Information Technology Database and Meaningful Use payment records. The study population included 1,340,387 Medicare fee-for-service (FFS) and Medicare Advantage participants age 65+ discharged from Florida hospitals over the period 2010-2012. Our outcome was all-cause 30-day rehospitalization (yes/no). The determinant of interest was hospital participation in Meaningful Use, identified through payment dates following hospitals’ attestation as meaningful users. Our case group included patients discharged from hospitals that participated in Meaningful Use during the study period. Comparison groups included patients discharged from hospitals that used paper records or EHRs without Meaningful Use participation. The differential timing of hospital participation in Meaningful Use was used to identify the program’s effect on rehospitalization, controlling for patient and hospital characteristics, including EHR use among hospitals that did not participate in Meaningful Use. Estimates were derived from logistic regression models with hospital and year fixed effects and standard errors adjusted for clustering within hospitals. A secondary analysis of Medicare beneficiaries with congestive heart failure (CHF) was conducted to examine patients with a high risk of readmission.

Results: Discharge from a hospital participating in Meaningful Use was associated with 3% lower odds of rehospitalization (Odds Ratio [OR]: 0.970, 95% Confidence Interval [CI]: 0.949-0.997) compared to discharge from a hospital using paper records. In our secondary analysis of CHF patients, hospital participation in Meaningful Use was associated with a greater decrease in the likelihood of readmission (OR: 0.940, 95% CI: 0.893-0.995) relative to the comparison group. In both analyses, patients discharged from hospitals with EHRs that did not participate in Meaningful Use had the same risk of readmission as patients discharged from hospitals that used paper records.

Discussion: Hospital participation in Meaningful Use may reduce the likelihood of rehospitalization for Medicare beneficiaries. Importantly, our study population included both Medicare FFS and Medicare Advantage participants. Our study is among the first to demonstrate the impact of Meaningful Use on the quality and value of care provided to the Medicare population.

Automating Personal Health Record Mammography Messages to Improve Mammography Screening Rates

Vaibhav Goyal, MD,1 Peter J Greco, MD,2 and David C Kaelber, MD, PhD, MPH1,2
1Department of Pediatrics, 2Center for Clinical Informatics Research and Education, The MetroHealth System, Case Western Reserve University, Cleveland OH

Abstract: Automated mammogram identification, ordering, and messaging system through standard electronic health record (EHR) and tethered personal health record (PHR) portal tools cant lead to an approximately 50% increase in screening mammograms completed over a 3 month period. EHR tethered PHRs can significantly improve screening mammogram completion rates, but still leave the majority of patients overdue for a screening mammogram without having their mammogram completed within 3 months of messaging.

Introduction: As electronic health records (EHRs) proliferate and their population health tools evolve and as EHR tethered personal health records (PHRs) are implemented and adopted, opportunities will increase to use EHR based population health tools with tethered PHRs to improve patient compliance with recommended preventative health activities. This study uses vendor based (Epic) population health tools and tethered PHR to improve mammography screening rates1,2.

Methods: Using standard commercial EHR functionality (Epic, Epic Corporation, Verona WI), a registry of women was developed who were 1) routinely seen in the last year in a single primary care internal medicine outpatient clinic, 2) due for but had not received a screening mammogram based on standard US Preventatives Services Task Force mammography screening guidelines and 3) subscribed to the EHR tethered PHR (MyChart). Screening mammograms were ordered for these women (so that an appointment could be made against the order) and then batch messages were sent to these women through the PHR. Screening mammography completion rate were compared among these women to women meeting the first two criteria at the same outpatient clinic but not on our PHR during the 3 months, after messaging through the PHR.

Results: 748 women met inclusion criteria for being in the outpatient clinic and for needing a screening mammogram. Table 1 shows the results of the 2 groups during the 3 months after the PHR messaging. Mammography screening completion rates were 15.4% in the PHR group compared to 7.0% in the non-PHR (control) group (p=0.002).

Table 1 – Screening Mammography Messaging Study Result

Conclusion: Standard EHR functionality that enables bulk patient identification and test ordering, coupled with bulk messaging to patients through an EHR tethered PHR can significantly improve screening mammogram completion rates, but still leave the majority of patients due for a screening mammogram without having their mammogram complete within 3 months of messaging. The approach has significant applicability to improve patient compliance with numerous preventative health activities.

Development of a concept-based template report editor for Radiological Information System

Carolina Valencia¹; Andrés Arbeláez MD¹, Sebastián Vélez-Zuluaga², Hugo Chvatal¹; Andrés Zapata¹, Lorena Tamayo¹, Ana C. Londoño¹, Jose F Florez-Arango² MD, PhD.
¹. Link Diagnóstico Digital. Medellín, Antioquia, Colombia.
². Grupo Informed, Facultad de Medicina, Universidad de Antioquia, Medellín, Antioquia, Colombia.

Introduction
The Radiological Society of North America (RSNA) has proposed the use of standardized templates for improving radiology-reporting practices. Use of standardized templates represents more specificity, completeness and homogenization of the radiological report’s content, homogenized findings, and is useful for data mining. Person, who creates templates under RSNA standards, requires knowledge of XML/HTML. RSNA templates uses RadLex lexicon (RL) as a reference model. RL is a tool that is not available in Spanish. RL’s terms are domain specific for radiology; there are cases where radiological reports’ intended users are not familiar with the radiological terms. The structure of the RSNA template facilitates translation of reports content into other domains³, as is the case of patients and referring physicians that use different language to express the same concept. RL does not cover all findings and outcomes that radiological reports use. For example RL does not include codes for different classification of arachnoid cysts (Galassi) and grades of appearance of subarachnoid hemorrhage (Fisher).

Methodology
Unified Medical Language System (UMLS) was the base for articulation of controlled vocabularies as LOINC, SNOMED-CT, CIE10 AND HL7. An automated process mapped RL into UMLS using a reference table RL – SNOMED-CT. This mapping allowed some RL concepts to automatically be translated into Spanish. Google’s automated translation service (GATS) served to generate more Spanish concepts. A human expert reviewed GATS and automatic mapping result for correctness. UFuRT framework² was the design and development method used to create a template designer and editing tool (TEDT).

Results
UMLS mapped into 30513 RL concepts. Supervised method provided a total of 24493 terms in Spanish. An intuitive template designer and editor tool is available. The newly created template editor and designer tool (TEDT) uses UMLS+RL ontology as knowledge engine. Templates created in TEDT provide customization of radiology reports while keeping the meaning of findings homogeneous no matter what the language of the intended user is. TEDT allows to new concepts into the Lexicon regardless of the language. Sample reports of Magnetic Resonance Imaging and Computed Tomography modalities served as seeds to build radiological report templates in different subspecialties such as neuroradiology. These templates contain sections and options with predetermined values created by subspecialized radiologists, decreasing the time used writing reports.

Discussion
The radiological and medical knowledge implemented into an interface to create standards-based, best-practice report templates is a step forward compared with the narrative conventional style of radiological reports. This consistently ordered structure helps to avoid errors of transcription (making the report precise, complete, and normalizing its content)³. Moreover the powerful feature of searching reports by pathology, particular finding and any other coded concept in different controlled vocabularies and language, allows data mining, leading to an enormous potential of identifying trends for specific goals in radiology practice, educational and research purposes.

iDECIDE Smartphone App for Personalized Messages for Nutrition and Fitness Goals
Irene van Woerden, M.S., Lauren Spano, B.S., Pedro Neto, HSD, Danielle Groat, B.S., M. Adela Grando, Ph.D.

Arizona State University, Tempe, Arizona; Federal University of Parana, Curitiba, PR Brazil

Abstract
Current smartphone applications (apps) related to health and fitness allow users to input goals and track progress but they lack personalized feedback to help detect obstacles and suggest alternatives to achieve behavioral changes for a healthier lifestyle. We propose an app, iDECIDE, to help users to identify their ‘persona’ which enables the app to deliver tailored recommendations, provide personalized encouragement and feedback messages and determine goal completion status with the aim to help users achieve their fitness and nutrition goals.

Introduction
It is difficult for individuals who seek to change to a healthy lifestyle to adopt all the necessary changes at once. The process requires that individuals acquire self-management skills by successfully achieving small goals while working towards a larger goal (1). The type of feedback an individual needs for goal achievement depends on their stage in the lifestyle transformation, e.g. athletes may need less encouragement than beginners to improve their physical performance (2). We are developing the iDECIDE app to help users identify their “persona” or stage of readiness to adopt a healthier lifestyle which will allow iDECIDE to provide tailored recommendations and messages to promote appropriate behavioral and lifestyle changes.

Methods
We observed over 9 hours of the Arizona Mayo Clinic “Live It!” program. “Live It!” meetings are facilitated by a registered dietician who delivers information related to weight loss while providing attendee specific information. The emphasis of the program is on educating individuals on how to live a healthier lifestyle.

We also conducted a survey of 28 individuals to acquire insights into the past and current successes and/or failures they experienced with maintaining healthy habits. The survey also asked questions that would help us understand the obstacles individuals face when making and keeping health related goals.

Results
The “Live It!” observations supplemented by the survey responses led us to identify three personas (Figure 1). The aspirant, inspired and athlete personas identify stages in the individual’s health journey and required level of guidance. For instance, the athlete has been working towards a healthier lifestyle for some time; compared with the other personas who may need more guidance and support as they encounter obstacles.

We deployed into the iDECIDE app a questionnaire that assess the persona of an individual (Figure 2). iDECIDE refers to the user’s persona and past encountered obstacles to tailor recommendations and messages, generate challenges and determine goal completion status. For instance, it would suggest a realistic plan when the aspirant-specific decision rules notice that the aspirant user has not completed an exercise goal to run and the obstacle of ‘not enough time to exercise’ is discovered. The app responds with “No worries if you did not find time for a run today, cleaning your house could help you burn some calories too!”

Future Work
iDECIDE will be tested with fictitious case scenarios created for each persona using data from the surveys and Mayo “Live It!” observations. Usability tests will help improve the app’s interface and functionalities.

Evaluation of a Statewide Online HIV-HCV-STD Clinical Education Program – Characterization of Healthcare Providers’ Professional Background, Self-Reported Knowledge Increase, and Intention to Change Clinical Practice

Dongwen Wang, PhD; Amneris Luque, MD; Terry Doll; Monica Barbosu MD, PhD; Matthew Bernhardt, MS
University of Rochester Medical Center, Rochester, NY 14642

Introduction
Clinical research in HIV, HCV and other STDs continuously generates new medical knowledge. Timely and effectively disseminating such knowledge to healthcare providers is critical for its translation into clinical practice. Leveraging a history of more than two decades providing in-person training, the New York State (NYS) HIV-HCV-STD Clinical Education Initiative (CEI) (www.ceitraining.org) started its online education program in 2009. Over the past five and half years, CEI has developed 200+ multimedia learning modules, ~100 online CME/CNE courses, a dozen interactive case simulation tools, and various other online resources. These resources are delivered through multiple platforms (websites, mobile apps, email newsletters, and online social networks) to tens of thousands of clinicians (physicians, nurses, etc.). CEI recently released its new student portal as a centralized system to manage online CME/CNE courses and program evaluation. Here we report the initial results to evaluate the CEI online education program, with analyses to characterize healthcare providers’ professional background, their self-reported knowledge increase, and intention to change clinical practice as the impacts of training.

Methods
We selected a study period from Nov. 3, 2014 (when the new CEI student portal was released) to Dec. 31, 2014 (when the quarterly reporting period ended). We queried the CEI student portal on clinicians’ evaluation of online CME/CNE courses with regard to: 1) usefulness/relevance of information; 2) easiness for comprehension; 3) knowledge of the trainer; and 4) appropriateness of the format. We assessed the impact of training through clinicians’ self-reported measures on: 1) intention to use knowledge; 2) knowledge level before and after training; and 3) plan to change clinical practice. For each measure, we further characterized clinicians’ personal (demographics and education level) and professional (occupation, practice years, employment setting and location, caseload, and specific clinical services) background, with Spearman’s correlation test to measure the association.

Results
A total of 335 clinician students completed 12 available online CME/CNE courses in the study period, with very positive evaluations (useful/relevant: 88.66%; easy comprehension: 87.76%; knowledgeable trainer: 91.04%; appropriate format: 84.18%). With regard to impact of training, 83.58% indicated intention to use the learned knowledge, 46.27% had at least 1-level knowledge increase, and 45.78% of those providing direct patient services expressed plan to change practice. Clinicians from the rural areas and with small patient caseload had more favorable experiences of the online training program. The impacts to knowledge use and change of clinical practice had mixed responses, depending on specific courses, clinicians’ years of practice, and particular types of services provided. Clinicians’ demographics, education levels, professions, and employment settings made no differences.

Conclusion
The initial assessment has shown that 1) clinicians are in general very positive about the CEI online education program, and 2) significant proportions of them plan to use the learned knowledge and to change clinical practice. Certain responses may depend on specific courses, clinicians’ experiences, and services provided. Clinicians from the rural areas and with small patient caseload are the groups most benefited from participating in online training. We plan to conduct follow-up studies to assess knowledge retention and to examine the actual impact to patient care.

Exploring Healthcare Mobility in the US to Improve Quality of Care: Preliminary Results
Karen H Wang1,2, Constance Carroll1,2, Joseph L Goulet2, Brenda Fenton2, Samah Fodeh1,2, Joseph J Erdos1,2, Marcella Nunez Smith1, Amy C Justice1,2, Cynthia A Brandt1,2
1 Department of Veterans Affairs, VA Connecticut Healthcare System 2Yale University School of Medicine

Abstract, 93 words
Mobile populations, who are often minority and low-income populations, are at risk for poor healthcare outcomes. These populations may experience poor healthcare coordination leading to either delays in or unnecessary care as healthcare systems are not designed for mobility. There are no agreed upon definitions for mobility for healthcare use, and thereby no standard measures and estimates of this type of mobility, or ‘healthcare mobility’. We used Veterans Health Administration national integrated health record systems with clinical data from over 100 facilities to explore healthcare mobility and to identify patterns in healthcare mobility.

Background:
Mobile/migrating populations, who are often minority and low-income populations, are at risk for poor health and healthcare outcomes. These populations may experience poor healthcare coordination leading to either delays in care or unnecessary care as the electronic health records are not personally-owned and as health information systems are not designed for population mobility across distinct border (e.g. regional health information systems). There are no agreed upon definitions for mobility for healthcare use, and therefore there are no standard measures and estimates of this type of mobility, or ‘healthcare mobility’.

Methods:
We used records from one million Veterans randomly selected from the Musculoskeletal Disorder (MSD) cohort, a previously characterized cohort with over five million Veterans who accessed the Veterans Affairs Healthcare System (VAHS) between 1/1/2001-12/31/2013 who have a MSD diagnosis as defined by at least two outpatient visits in 18 months or at least one inpatient visit with an MSD code. Patients were then followed retro- and prospectively from the date of the first MSD diagnosis. Data, extracted from the VAHS Electronic Medical Records, contain demographic and clinical characteristics and healthcare utilization. For this study, we defined ‘healthcare mobility’ as the use of more than one VAHS outpatient facility during the study period. We examined characteristics of mobility based on migration literature, including the frequency of change in outpatient facilities, duration of time per facility, and geographic distance between facilities.

Results: Among this random sample of 1 million Veterans, 14% (n=147,720) had used two or more healthcare facilities. Among the healthcare mobile individuals, there were 82% (n=121,061) with two, 14% (n=20,684) with three, 2.9% (n=4326) with three, and 1.1% (n=1,648) with five or more facility used. Veterans used on average 2.8 facilities. Among the healthcare mobile between two facilities, the median number of total visits alternating between two facilities was 7, and approximately 75% Veterans alternated between two facilities no more than 12 times during the study period. The average duration spent at a facility was 24 months. The figure demonstrates number of uses per year for the sample. To elucidate other characteristics of mobility at more than two facilities we will use more complex analytical tools such as sequential data mining.

Conclusion:
Individuals within the VAHS are healthcare mobile between different outpatient facilities. Care coordination across these facilities is needed to ensure quality healthcare for mobile individuals. Future studies will examine the types of healthcare accessed between the facilities and assess for duplicative services and costs.
Automatically Screening Possible Chemoresistance Genes of Bladder Cancer Drugs

Liwei Wang, PhD1, Jingde Zhu, PhD2, Qian Zhu, PhD3

1Department of Medical Informatics, School of Public Health, Jilin University, Changchun 130021, Jilin, China
2Cancer Epigenetics Program, Anhui Cancer Hospital, Hefei 230031, Anhui, China
3Department of Information Systems, University of Maryland Baltimore County, Baltimore, MD 21055, USA

Abstract
Bladder cancer is highly refractory to the drug therapy due to chemoresistance, which prevents effective chemotherapy [1]. At present the mechanistic understanding of cancer chemoresistance remains elusive [1]. This study aims to predict chemoresistance genes of bladder cancer drugs including Adriamycin, Cisplatin, and Paclitaxel, from a large scale of literature data, SemMedDB. The findings produced from this study would consequently provide novel hypotheses to further investigate bladder cancer chemoresistance mechanisms by biologists and/or oncologists.

Materials and Methods
SemMedDB containing 70 million semantic predications extracted from the PubMed [2], has been explored to identify possible chemoresistance genes. To be specific, a two-step approach has been applied to predict possible chemoresistance genes from SemMedDB, 1) genes associated with “Drug resistance concepts” via specific properties, such as “stimulates” and genes associated with “bladder cancer drugs” via “inhibits” have been extracted automatically and evaluated manually by Dr. Jingde Zhu, 2) one inference rule shown in Figure 1 has been designed for chemoresistance gene prediction.

Preliminary Results
Total distinct 71 genes associated with 15 drug resistance concepts have been identified for the 3 bladder cancer drugs from the SemMedDB. The individual gene list obtained for each bladder cancer drug is shown in Table 1.

Table 1. Sample set of the predicted chemoresistance genes of bladder cancer drugs

<table>
<thead>
<tr>
<th>Bladder cancer drugs</th>
<th>Predicted genes related to chemoresistance</th>
</tr>

</tr>
<tr>
<td>Cisplatin</td>
<td>ABCB1, ATP phosphohydrolase</td>
</tr>
<tr>
<td>Paclitaxel</td>
<td>Cytochrome P450, EPHB2, MAPK1, MAPK8, ABCB1, ABCG2, ADM, APP, ARL4C, ALPK1, Albumins, ATP phosphohydrolase, caspase-3, caspase-9, constitutive androstanone receptor, APP, AHR, ATP phosphohydrolase</td>
</tr>
</tbody>
</table>

Discussion and Conclusion
To our knowledge, this is the first attempt to automatically screening possible chemoresistance genes for bladder cancer drugs from the literature. Further experimental evaluation will be proposed for those predicted genes by Dr. Jingde Zhu’s lab. In addition to the evaluation, more systematic approach by exploring more diverse types of data, including pharmacogenomics, systems biology data and developing more complex inference rules along with the advanced informatics approaches, such as network-based analysis would be used to identify more candidate chemoresistance genes related to bladder cancer drugs or other types of cancer drugs.

Building and evaluating predictive models for postoperative ileus prior to colorectal surgery
Xuya Wang\textsuperscript{1,2}, M.S., Raul Caso Caso\textsuperscript{2}, B.S., and Yindalon Aphinyanaphongs\textsuperscript{1,2}, M.D., Ph.D.
\textsuperscript{1}Center for Health Informatics and Bioinformatics, NYU Langone Medical Center, New York, NY
\textsuperscript{2}NYU School of Medicine, New York, NY

\textbf{BACKGROUND:} Postoperative ileus (POI) is an abnormal pattern of gastrointestinal motility, frequently occurring after abdominal surgery with an incidence of 3-32\%.\textsuperscript{1} It incurs a significant resource burden on institutions\textsuperscript{2}. In this study, we evaluated a predictive model for POI using variables immediately after the preoperative assessment. Creating a model at this point in time will allow for POI-reducing interventions that include avoidance of mechanical bowel preparation or nasogastric tube placement, performance of minimally invasive surgery when feasible, limiting opioid use, and early postoperative ambulation and feeding.

\textbf{METHODS:} We used the American College of Surgeons' 2012 National Surgical Quality Improvement Program (NSQIP) database, a multicenter (>250 hospitals) database. Of 16,981 colectomy patients, 2,716 (16\%) developed POI. We performed two experiments. For both experiments, we evaluated performance using 5 fold stratified nested cross validation. In the first experiment we evaluated classifier performance using 12 predictors of POI selected from the literature. In the second experiment, we evaluated classifier performance considering all 37 preoperative variables. We compared Support Vector Machine (SVM), Random Forest (RF), Logistic Regression (LR), Linear Discriminant Analysis (LDA) and Quadratic Discriminant Analysis (QDA) by examining the areas under the curves (AUC). We compared AUC values with the Wilcoxon rank sum test with adjusted p-values by the Benjamini & Hochberg procedure.

\textbf{RESULTS:} In the first experiment, the mean AUC for the LR classifier was 0.654, 0.653 for LDA, 0.646 for QDA, 0.633 for RF, and 0.550 for SVM. LR was statistically significantly different (Adjusted p<0.05) than RF and SVM. In the first experiment, the top 4 variables in the logistic regression model for one data split were emergency case, dyspnea, gender, and serum albumin. In the second experiment, the mean AUC for the LR classifier was 0.672, 0.671 for LDA, 0.640 for QDA, 0.650 for RF, and 0.595 for SVM. LR was statistically significantly different than QDA, RF, and SVM. In the second experiment, the top 8 variables in the logistic regression model for one data split were estimated probability of morbidity, estimated probability of mortality, dialysis, elective surgery, ventilator dependence, history of congestive heart failure, gender, and prior chemotherapy treatment.

\textbf{CONCLUSION:} The LR model, with a mean AUC of 0.672, was the highest performing classifier with statistically significant discrimination. Model building can be utilized to create a predictive model for POI to be implemented immediately following the preoperative assessment.

The American College of Surgeons NSQIP and the hospitals participating in the ACS NSQIP are the source of the data used herein; they have not verified and are not responsible for the statistical validity of the data analysis or the conclusions derived by the authors.

Integrating Analytics and Business Intelligence (BI) into a Health Informatics Curriculum: Pros, Cons and Opportunities

Victoria Wangia-Anderson, PhD1
1University of Cincinnati, Cincinnati, Ohio

Abstract Healthcare is drowning in data as a result of the rapid adoption of electronic health records (EHRs), and health informatics professionals with strong data analytics and BI skills are needed. A survey was administered to gather data about attitudes towards a curriculum that integrates analytics into a Health Informatics curriculum. The results showed positive attitude towards the approach and overwhelming support to maintain the integration and focus on specific areas of analytics.

Introduction Rapid evolution of healthcare data analytics and business intelligence resources has generated information that can be utilized to plan for population health interventions, to reduce healthcare costs, to increase patient centeredness and to improve financial gains. Over the past decade, we have witnessed the active application of computer science and data mining and warehousing tools to data, to progressively convert it to information, knowledge and wisdom. Access to this data and the application of analytics skills can enable healthcare organizations to improve risk analyses, patient outcomes, resource availability, referrals, performance metrics and readmission rates. As electronic information continues to grow exponentially in the healthcare industry due to the rapid adoption of EHRs, there is realization that the data and analytics skills gap already evident in other industries will be a concern for healthcare in the near future. A graduate program in Health Informatics program has begun addressing this need by integrating Analytics and Business Intelligence (BI) in the Health Informatics curriculum. Qualitative and quantitative data was collected from students and faculty to assess their attitudes and perspectives towards the integrated curriculum.

Materials and Methods For this case study, qualitative and quantitative data was collected through a questionnaire. The questionnaire was administered to graduate students, affiliates and faculty (N = 60) teaching in the Health Informatics Graduate program. The questionnaire gathered quantitative data about attitudes and qualitative data about: 1) The benefits of introducing basic and advanced data analytics and BI competencies in the Health Informatics curriculum, 2) Weaknesses, 3) Opportunities, and 4) Priority areas for curriculum focus.

Results The results showed 90% of the respondents agreed that current and future Health Informatics practitioners needed to be equipped with both informatics and analytics skills to balance the focus on technology with data analysis and mining, forecasting and BI. Also, 90% of the respondents had a positive attitude towards the integrated curriculum and the purpose. The respondents all agreed that academic-industry partnership were crucial for staying abreast of the trends in Analytics and BI, and those partnerships needed to be further developed. There was consensus that there is already a data analytics and BI skills gap in healthcare organizations and this would have adverse implication on the organizations, and that health informatics academic programs needed to play a key role in contributing to training the needed workforce. The recommended analytics areas of focus fell in the categories of predictive and descriptive analytics. Areas related to prescriptive analytics were less popular.

Conclusion The integration of Analytics and Business Intelligence in Health Informatics programs is desirable, and professionals in healthcare with health informatics, data analytics and BI skills will be able to make significant needed contributions to the healthcare industry. Industry partners are developing cutting edge health data analytics and BI tools, and academic-industry partnerships are crucial for curriculum to remain relevant. Academic institutions can contribute by training well prepared professionals able to fill the workforce gap.
Pediatric Venous Thrombus Embolus (VTE) Screening Tool: Design, Implementation and Continuous Improvement of a Complex Clinical Decision Support Tool

Emily C. Webber, MD; Indiana University School of Medicine, Pediatrics; Indianapolis, IN
Cara Willey, RN; Indiana University Health Information Services; Indianapolis, IN
Michele Saysana, MD; Indiana University School of Medicine, Pediatrics; Indianapolis, IN
Arash Mahajerin, MD; Children’s Hospital of Orange County; Orange, CA

Background Pediatric venous thrombus emboli (VTE), including both deep venous thrombus (DVT) and pulmonary embolus (PE), is increasing in incidence. The objective of this project was to design a tool integrated into a vendor electronic medical record (EMR) to apply institutional VTE screening guidelines, increase screening, document VTE risk, and provide patient specific clinical decision support (CDS).

EMR tool The VTE tool in the EMR consists of four parts: a screening form triggered by the patient age and admission presented to the physician, clinical decision logic rules calculation of risk, documentation of the risk, and suggestion of patient specific order suggestions based on risk. Recommendations are tailored based on risk factors and contraindications, which were analyzed in a previous publication.

Results The tool was implemented in August 2013 for 12 to 17 year olds, who account for 21% of all inpatient admissions at our institution. Screening rates have been tracked monthly since implementation. During the first 22 months, 2314 patients were screened, with a monthly average of 105 (or 68.3%). Figure 1 illustrates the distribution of risk; the majority of patients screened low risk (91 patients/month average). Moderate risk patients averaged 9.5 patients per month, and high risk patients averaged 2.36 patients per month. Physician orders were analyzed for subgroup of 1318 patients from January to December 2014. During the study period, we identified rates of SCD orders (24.7 average/month) and enoxaparin orders (1.6 average/month). There was an average of 8.75 moderate risk patients and 2.42 high risk patients each month during this time. The assessment found that not all orders were placed using the automated suggestions. There have been no VTE identified in the study population, compared to 3 events in patients who would have qualified for screening in the 12 months prior to the implementation of the VTE tool in the EMR.

Conclusions and challenges Utilizing the integrated EMR tool successfully allowed for screening of our adolescent inpatients and identified moderate and high risk children. Risk stratification is now more consistently documented, and evaluation of order accuracy and efficiency is also being evaluated. Prior to the EMR tool, patients’ VTE risk was not routinely assessed or documented, thus we did not have a reliable baseline of orders correlating to patient risk, however we suspect these higher level of orders for prophylaxis were due to the increased visibility and awareness the EMR tool and associated education. Challenges remain in how to best determine the impact of the EMR tool on ordering practices, since overall VTE prophylaxis orders increased even among patients not screened. Current improvements to the VTE tool include automated presentation at times of clinical status change such as a change in ambulatory status or placement of a central line.

Figure 1. Categories of low, moderate, and high risk for VTE in the screened population.
A method to automatically create titles of clinical notes in electronic medical records

Alan Weiss, MD¹, MBA, Mehdi Rais, MS¹,², Rehal Bojhani MD¹, Dean Sittig, PhD¹,²

¹Memorial Hermann Health System, Houston, TX, USA
²University of Texas Health Science Center at Houston, Houston, TX, USA

ABSTRACT

Background/Objective

There are minimal evidence-based standards to define or benchmark the ease of access to contents of clinical documentation, specifically the clinical note. Outpatient clinical notes help record care, document therapeutic plans, and support a variety of functions that include communication, epidemiology, medical training, medical jurisprudence, and billing. A clinical note title provides a potential glimpse to the issues dealt with on the day of the visit; it can allow providers to quickly identify significant findings, diagnoses and/or results. Without opening and reading the entire note to understand its contents, a title can help providers decide which notes to open and where to focus their attention. In this podium abstract, we look to improve access to the clinical note content utilizing techniques to populate clinical note titles from a database developed from most commonly used billing codes which were translated into clinically relevant abbreviated terminologies, and describe methods to evaluate the impact of these changes. We sought to develop and validate methods to automatically create clinical note titles utilizing clinical and billing system data.

Methods

We identified code sets (ICD9, SNOMED, CPT) and respective descriptions used during the course of visits, and designed and validated a set of rules to create clinical note titles based upon these elements. This research team provided input on a preliminary set of rules to create titles by focusing on the top 95% of codes/descriptions (1200 codes/descriptions in total) used for all patients during this 3 year period. Based on this input, we transformed 2,224,167 clinical note titles from a three year period to assess their performance as compared to the original note title.) This research team is currently assessing the impact of these generated titles by examining the created title against the original title for brevity of final title terms, and accuracy of the title in relation to the note itself.

Results

An initial review by this research team of 200 notes, we were able to create clinically understandable short form through transformation of the billing data in a significant portion of clinical notes. We are currently measuring the feedback from a panel of providers on their perceptions in terms of value versus the alternative title, brevity and accuracy and look forward to sharing those results.

Discussion

We developed a set of rules to create clinical note titles utilizing a data base created from all billing codes used for clinical notes over a three year period within our hospital system which were then converted into an abbreviated medical terminology for insertion into titles. In the absence of missing data such as problem lists, this proved to be problematic when creating clinical note titles, as part of the logic relies upon this; we are exploring options to help resolve problem list gaps. We recognize that there are many other ways to do this (i.e. machine learning techniques) which we explore and invite audience for their thoughts.
Engaging Patients & Families in Contributing Patient-Reported Outcomes to a Pediatric Disease Registry for Comparative Effectiveness Research

Elissa R. Weitzman, ScD, MSc¹ ², Parissa K. Salimian, BA¹, Karen Olson, PhD¹ ², Kenneth Mandl, MD, MPH¹ ², Marc D. Natter, MD¹ ²

¹Boston Children’s Hospital, Boston, MA; ²Harvard Medical School, Boston, MA

Introduction

The voice of the patient is largely missing from large federally funded observational cohort studies for use in medication safety surveillance and comparative effectiveness research. Proven approaches to collecting these data are needed to drive knowledge and advance treatment.

Methods

Participants and parents from 4 Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry sites were recruited/consented contingent on child diagnosis of juvenile idiopathic arthritis (JIA), lupus, or mixed connective tissue disease and use of a treatment medication. Patient reported outcome (PRO) measures about information needs, adverse drug reactions/events (ADRs)/(AEs), and quality of life were collected using a novel tool that enabled in-clinic reporting via tablet and linkage with clinical registry data.¹ PROs were analyzed to identify participant concerns and data relevant to addressing them. Site IRBs approved the research.

Evaluation Results

186 parents and 88 self-reporting teens have entered data (participation rate 82%). Of parents, 54% have children 2-12 years old, 46% have a teen. Among patients, most have JIA (93%); 78% are female. 38% of parents rated “serious long-term side effects of medication” their top concern, followed by “medication safety” (29%). Other issues (e.g., dose/schedule) were of lesser concern. Aggregate PROs address top concerns and knowledge gaps (Figure 1).

Results: 27% of parents reported a medication related ADR/AE. Of these, 55% (15% in all) reported multiple. Problems were common among methotrexate users: 54% of parents reported child restlessness/irritability, 52% reported stomach ache, nausea, or vomiting.

Conclusion

Findings support acceptability and utility of an informatics-enabled participatory model of engaging a clinical registry cohort in providing health information to answer their prioritized questions. Future work will focus on evaluating feedback of summary information to participants to ascertain value for decision-making, and connect Registry with PRO data to investigate treatment experiences in relation to clinical disease measures. This work is supported by 1R01LM011185.

**Transition of Care from an Academic Cancer Center to Community Providers and Survivorship care: Would a Patient Care Team Portal Help?**

Philip E. Whalen MA, Marina Oktapodas, and Carmelo Gaudioso MD PhD Roswell Park Cancer Institute Buffalo, NY

**Abstract**

In the transition of care from an academic cancer center to community providers and survivorship, cancer patients’ continuity and quality of care are susceptible to the vagaries of communication, care coordination, and the relationship between providers. The aims of the present study were to a) characterize patients and provider’s experience with transition of care (e.g., needs, preferences, issues, and concerns); b) discern their attitudes and openness toward a patient care team portal designed to facilitate communication and coordination of transitional and survivorship care; and c) identify the essential functional requirements of the proposed patient care team portal. This research hopes to better future interactions between patients, academic cancer centers, and community providers through a patient care team portal designed to facilitate the sharing of information and knowledge in such a way that the transition of care and survivorship care processes are improved.

**Introduction and Background**

Following the HITECH act of 2009, many healthcare institutes began the construction and use of electronic medical records (EMR). Because of this, adoption of portal technologies, which have the potential to fulfill meaningful use requirements of the act, has become widespread with twenty-six billion dollars of a total government allotted thirty-three billion dollars of incentive money pledged as of September 2014 (CMS Data). While a patient portal has been shown to serve as an effective patient-provider communication tool, it requires optimization guided by well characterized users’ preferences and concerns to effectively facilitate transition of care and survivorship care.

**Methodology**

Qualitative survey data were collected during single sessions of focus groups following guided and open discussions examining the potential benefits and issues of using a patient care team portal during transitional and survivorship care. Surveys and discussions were conducted with three separate groups: 42 cancer patients, 32 community physicians, and 7 academic cancer center physicians. Themes were identified using a methodology presented in E.H. Bradley et al., 2007, utilizing conceptual codes and inductive reasoning.

**Results**

A few main themes and concerns emerged during group discussion of the use of patient care team portals in support of survivorship and transition of care: a) a need for better communication between all three cohorts; b) a lack of medical information sharing and care coordination between all three cohorts; and c) a lack of trust between the community physicians and academic cancer center physicians regarding the return of the patient to community care. Themes A and B were endorsed by all cohorts while theme C was primarily endorsed by the two physician cohorts. As such, provider-patient and inter-provider communication, sharing of medical records and disease specific educational information, and guidance were suggested as features of the portal to alleviate these concerns and provide a more coordinated care team as well as an overall improvement in transition of care and survivorship.

**Conclusion**

Recognizing the limitation of the small number of academic physicians, the present study demonstrates the strong favor of stakeholders in the development of a patient-provider portal. Main themes and issues were identified and solutions were developed. Using these qualitative data, we plan to implement and test in real time a module of an existing portal as a central information hub to promote coordination of care and effective communication between all stakeholders.
Increasing Patient Enrollment in Clinical Trials Using a Web Based Recruitment Application

Nancy Whipple, BSN, MS, MM1, Inna Natanel, BA1, Harley Ramelson, MD, MPH1,2,3
1Partners HealthCare Inc, Wellesley MA; 2Harvard Medical School, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA

One study found that in the United States, 34% of the trials recruited less than 75% of their planned sample.1 The primary barriers include: patients’ lack of awareness of relevant trials (40% of adults report that they do not understand the idea of a clinical trial), patients’ fear of being a test subject; concerns about cost and insurance coverage, and general fear of the unknown. Traditional methods of recruitment can be both costly and difficult to anticipate or control.

At Partners HealthCare Systems (PHS) there are over one million outpatient visits and over one hundred thousand inpatient admissions each year. Yet only a small percentage of patients are involved in research studies and clinical trials. In the spring of 2015 PHS will launch a new secure website to assist in the recruitment of patients into clinical trials. Health On-Line for Patient Enrichment (HOPE) is a tool that is designed to provide patients with a view of current clinical trials. It will simplify the process of communication between the patient and the trial administrator and will potentially increase the number of patients enrolled in clinical trials. HOPE will be accessible via a link that is prominently shown on the home page of the PHS Patient Portal: Patient Gateway. Because Patient Gateway is supported by the patient’s clinicians, patients have a high degree of confidence in the content of the site and a feeling that the site is a credible source of information. Patients will receive a secure mail message from the HOPE Team inviting them to explore the site.

The HOPE site will directly address patient concerns and fears. The site will describe the numerous benefits of participating in clinical trials. The patient will be guided through the process of expressing interest in a clinical trial. The site will also provide detailed information about the trial, so that the patient can be more informed about the specific trial. This Information includes clinical eligibility, patient responsibilities (time commitment and activities), duration of trial, and compensation.

Patient experience goals:

- To provide a sense of community, focused, disease-specific, health areas patients may join are created. Community membership provides patients with targeted educational material and events (e.g. webinars, teleconferences), as well as a list of all active trials and the patient’s relationship to them.
- To keep patients engaged, periodic messages are sent that are of particular interest to them. Recipients are based on the communities patients have joined and trials they have expressed interest in. In addition, educational materials, web conferences/dial-in informational sessions, and news items are updated frequently.
- To entice patients to periodically return to the HOPE site, a list of timely, newsworthy items related specifically to HOPE and to clinical trials in general is maintained.

Associated with the HOPE site is an administration tool to maintain the content of the site. The tool also provides the ability to update the status of the patient in relation to a trial (e.g. enrolled, ineligible, and dropped out). We will also be able to report on patient activity on the site. Standard reports will provide usage of specific functionality including measuring the interest in particular health areas, educational materials and events. The analysis will include determining the effectiveness of the various components of the site and determining both the rates of trial enrollment and the rate of retention of enrolled patients. It is our hypothesis that trial enrollment will increase and effective recruitment will lead to long term patient retention.

Augmenting Psychiatric Care: A Participatory Mobile Framework

Kandace M. Whiting, DNP, RN-BC, James Rosser, LCSW, Kenneth Wells, MD, MPH, Armen Arevian, MD, PhD
UCLA Resnick Neuropsychiatric Hospital, Los Angeles

Introduction

Mobile interventions are increasingly used to augment care and facilitate home-based communication, real-time monitoring, and just-in-time interventions. As more mobile health interventions are implemented, there is increasing evidence that a “one size fits all” approach has significant limitations. Community-partnered participatory techniques (CPPR) improve patient engagement and clinical outcomes; however, they are resource intensive and costly to implement in given the iterative nature of intervention technology development. The Chorus Participatory Mobile Framework (CPMF) is designed to address these challenges by allowing individuals to create mobile health interventions quickly at low cost using a simple web interface.

Aim

The UCLA Neuropsychiatric Hospital Partial Hospitalization Programs (PHP) provide psychiatric services for adults and children with acute mental illness on an outpatient basis. Though patients receive extensive support during program hours, support provided after program hours is limited. Consistently, patient satisfaction metrics highlight after hours support as an area for program improvement. To address this gap, we developed patient-tailored mobile interventions such as SMS reminders and mobile web applications to provide patients additional support after hours.

Methods

Using the CPMF, we partnered with providers and patients to develop patient-tailored mobile interventions such as SMS reminders and mobile web application. To do so, we invited PHP providers and patients to in-person workshops to develop initial mobile intervention tools. These workshops involved an iterative cycle of four steps: 1) identification of barriers and opportunities for improvement, 2) generation of messaging content, 3) creating working prototypes of the mobile tool, and 4) testing mobile tools in real-time. Developed tools are customizable and intended to be specifically tailored to individual patient treatment plans, communication preferences, and experiences. After initial prototypes were developed, we offered PHP patients the opportunity to receive additional support after hours by partnering with providers to develop individualized interventions using the CPMF in real-time. Therefore, patients were able to directly create the mobile interventions that they would then use.

Conclusions

The CPMF provides a novel method for providers and patients to co-create mobile health interventions in real-time designed to augment outpatient psychiatric services. This method combines the best practices of community-partnered participatory research principles along with patient-centered design to ensure that health interventions are relevant to individual patient needs. Importantly, CPMF meets a key methods gap by offering an opportunity to implement scalable methods to engage patients, families, and providers through personalized and adaptable mobile health interventions.

A Centralized Data Collection and Management Tool in the VA: REDCap

Erika Whittier, MPH,1 Denise M. Hynes, MPH, PhD, RN,1,2 Peter Watson, PhD,3,4
1VA Information Resource Center, Edward Hines, Jr. VA Hospital, Hines, IL;2College of Medicine and School of Public Health, University of Illinois at Chicago, Chicago, IL; 3University of Colorado School of Medicine, Denver, CO; 4Denver VA Medical Center, Denver, CO;

Introduction:
The Department of Veterans Affairs (VA), Office of Research and Development (ORD), supports health research at more than 150 VA facilities nationwide.1 This research has significantly contributed to advancements in health care for Veterans and created innovations that advance health care for the nation. Collaborations that bring together clinicians, program leaders, and researchers within VA facilities, across multiple VA sites and across service areas are critical to this success, and finding efficient ways to bridge research coordination across these areas is essential. REDCap, Research Electronic Data Capture, a web-based application software that allows users to build, share and manage databases and surveys quickly and securely,2 is an instrumental part of bridging these efforts.

Methods:
The VA Information Resource Center (VIReC) partnered with the VA Informatics and Computing Infrastructure (VINCI) to manage the implementation of REDCap within the VA. REDCap is used widely by groups (including National Institutes of Health and numerous academic affiliates of VA Medical Centers for research purposes). Many VA investigators have experience with REDCap through their academic affiliations, thus the community of current REDCap users within the VA is large.

Sought a data management tool that would allow integration across multiple project teams within the VA that: 1) Resides in a centralized location, 2) Provides a secure way of collecting and sharing data in a web-based environment, 3) Provides a secure tool to develop surveys and databases from conception to production on the Web without additional software requirements for researchers.

The implementation began with phased roll-outs across the VA. REDCap was first tested with five groups of testers: three experienced with REDCap, two groups with no experience. Groups were given details instructions and each asked to complete project specific tasks in REDCap. The next phase of Beta testing surveyed 30 beta test users to examine utility of the system, utility of education materials and users’ experience.

Conclusions:
VA REDCap is currently available to researchers with Institutional Review Board Approved research protocols and Quality Enhancement Research Initiative Investigators. Users are able to set up databases, and collect and manage data which is stored on a centralized secure server. Users are also able to generate surveys that can be administered through the VA’s intranet. There are currently 257 projects and 592 users. Examples of current projects include a database for managing data collected from a pilot intervention to improve care coordination between VA and non-VA providers using the Blue Button feature of MyHealthE Vet and a cross-sectional study designed to examine suicide risk assessment practices of VHA Suicide Prevention Coordinators.

Routine Collection of Patient-Reported Data in Electronic Form in Clinical Settings: An Analysis of Available Technologies

Adam B. Wilcox, PhD; Susan Tew, BSN; Justin Poll, PhD
Intermountain Healthcare, Salt Lake City, UT

Introduction

Studies of the relative contribution of different determinants to health estimate medical care as a minor contributor, while social circumstances and behaviors contributing the majority of the difference in health outcomes. These factors often must be assessed from patients directly. However, if they are not recorded in electronic form, the data are not available for decision support, longitudinal monitoring or retrospective analysis. Collecting patient-reported data in electronic form is thus critical for transforming the healthcare system.

Currently, most collection of patient-reported data is done with paper forms, but must be transcribed to electronic form. The high cost of transcription makes this approach rarely sustainable. Patient portals can collect information from patients directly in electronic form, but are rarely used and do not support clinical workflows. Two additional methods for patient data collection, that support clinical workflows but do not require manual transcription are scanned forms and tablet-based data collection. Here we describe our analysis comparing scanned forms and tablet computers for collecting patient-reported data.

Methods

Three experts in data collection applications, patient-facing technology, and data collection methods performed this analysis. First, we identified a list of important characteristics important for data collection technologies. For each characteristic, we then rated the two technologies on a 3-point scale (positive, neutral, negative) in terms of how well the characteristic was supported by the technology. Characteristics were then grouped by functional categories, and the technologies were compared across the different categories.

Results

Thirteen characteristics among 4 functional categories were compared. Overall support was equal between scanning and tablets for categories of institutional cost, security, and patient acceptance. However, for functionality, tablets were better than scanned forms for 5 of 6 characteristics. These results suggested a strong advantage for tablets over scanned forms.

Characteristics where tablets provided better support were data security, patient matching, workflow integration, data timeliness, branching logic, extensibility, and patient preference. Scanned forms had lower theft risk, had better disaster recovery support, and lower patient-perceived security risk. The technologies were perceived as equivalent in overall equipment costs, infection control risk, and training costs.

Discussion

Our analysis concluded that tablets were better than scanned forms for collecting patient-reported data in electronic form. The differences were primarily due to advantages in functionality, where support for branching logic and extensibility were important advantages for tablets. Others have studied different technologies for data collection including tablets and scanned forms, however, these studies presumed use of the technology by research data collectors, rather than by patients. Many of the categories used were consistent among the studies, which supports the overall conclusion of the analysis. Future work should focus on demonstrating the use of tablets for patient-reported data collection, and analysis of the adoption and consistency of use.

Using Informatics Tools to Standardize the Request, Adjudication and Monitoring of Non Formulary Agents at a VA Facility
Lisa Winterbottom MD, MPH, Judith McConnachie MPH, Thomas Brenk MPA, Jianji Yang PhD, Brian M Wilcox, Pharm.D
VA Portland Healthcare System, Portland, Oregon

Introduction
VA’s electronic medical record system does not have a standardized platform to order non-formulary medications. Facilities developed their own methods to review, approve and order these medications, usually with consult submission to approving pharmacists. The request, adjudication process and monitoring vary by site. When the requests are approved, patients are placed on medications that are most likely high cost and/or have significant safety concerns, requiring close oversight and monitoring. Review of this care requires manual chart reviews that are labor intensive and may not be consistently done for all patients on non-formulary medications. This is a well-recognized patient safety and cost issue in all facilities and authors submitted a proposal and were awarded with a VA Innovation Grant. The grant allows us to collaborate with VA Pharmacy Benefits Management (PBM) to re-engineer and standardize the non-formulary medication request/approval and patient monitoring processes, leveraging capabilities of clinical informatics tools to efficiently support real-time population monitoring. The program will consist of three components: 1) development of standardized tools to support non-formulary medication ordering, review, and approval for use; 2) development of a registry to support population level and efficient patient-level clinical monitoring; and 3) human intervention by a dedicated pharmacist to use the developed tools for appropriate review, approval, and monitoring of patients. The program will be piloted at the VA Portland Health Care System (VAPORHCS) with a robust evaluation to determine impact. After initial piloting, the program will be extended to additional sites in the region with consideration for national use.

Proposed Methods
Program development: A clinical informatics team at VAPORHCS will partner with PBM to develop the standardized Consult template prototype in VA’s Computerized Patient Record System (CPRS) to collect clinically relevant data based on the medication’s “criteria for use” at the time medication request. This information may include the medication name, indication, planned duration, last labs etc. as well as specialized fields of information for a specific drug or drug class. We will partner with VISN 21 on the use of their developed adjudication process involving a uniform note using several searchable data fields. A web-based non-formulary medication monitoring registry will be developed to support two aspects of monitoring. Firstly, it will help track the status of all requests from submission to approval/denial. Secondly and importantly, the registry will support close monitoring of the patients on any non-formulary medications at a population-level as well as a detailed patient-specific level for safety reviews by assembling and displaying clinically relevant information at a glance. Built-in registry logic will also highlight possible concern areas to alert reviewers of priority reviews needed. A dedicated pharmacist will both review requests for the designated non-formulary medications as well as use the registry for close monitoring and timely intervention as needed for patients using the designated medications. Interventions may include stopping medications, titrating doses, directing patient to provider review, etc.

Pilot and Evaluation: The program will be tested in the VAPORHCS with selected medications. Evaluation will be performed to assess improvements in safety monitoring and early intervention when indicated (e.g. doses adjusted, labs ordered, etc); staff satisfaction with process for monitoring non-formulary medications; and financial impacts. Rollout to additional test facilities and nationwide: If the evaluation indicates positive impact, the program is expected to roll out to additional test facilities and then nationwide.

Expected Impact and Current Status
We expect Veterans will benefit due to the improved patient safety from active monitoring. Providers and pharmacists will experience a more efficient monitoring process. Facilities may see a reduction in medication cost due to the standardized request process and better management. The architecture of the informatics tools (CPRS consult and registry) proposed (Figure 1). Input on drug candidates solicited; chart reviews being performed to assess identification of data points. Partnerships with external and internal stakeholders are established. Tools to be tailored to drugs selected with goals of scalability, feasibility, sustainability.
A BI Tool to Monitor the Intervention Efficiency of Antibiotic Therapy in Leukemia Patients
Cai Wu, MS
The University of Texas MD Anderson Cancer Center, Houston, TX

Abstract
A BI tool with Hyperion Reporting Studio was developed to monitor the efficiency of the intervention process for the MDACC antimicrobial stewardship team on daptomycin, linezolid, vancomycin usage in leukemia patients. Daily defined dose (DDD) per 1000 patient days, days of therapy (DOT) per 1000 patient days, Cost per 1000 patient days, mean duration per 1000 patient days, and patient length of stay (LOS) were the measurement indexes. The SPC control chart of the each index was generated to measure the efficiency of the intervention on the antibiotics.

Introduction
The use of broad-spectrum antibiotics is a well-known risk factor for infection in bacterial and fungal in leukemia patients. Increasing of duration of patient exposure to antimicrobials increase the likelihood of colonization with resistant organisms. The University of Texas MD Anderson Cancer Center (MDACC) antimicrobial stewardship aims to optimize antimicrobial use in hospitalized cancer patients by involving a continuous effort of healthcare providers. Its goals are to improve outcomes, minimize therapy cost, and reduce the resistance of antimicrobial use. In order to monitor the efficiency of the intervention process and analyze the duration of antibiotic therapy in leukemia patients, a business intelligence (BI) tool with Hyperion Reporting Studio was developed for Antimicrobial stewardship team.

Measurement Indexes
Based on WHO Anatomical Therapeutic Chemical (ATC) Classification System Defined Daily Dose (DDD), DDD per 1000 patient days, days of therapy (DOT) per 1000 patient days, cost per 1000 patient days, mean duration per 1000 patient days, and patient length of stay (LOS) were used for the measurement of the efficiency of the intervention process. The selected antibiotics were daptomycin, linezolid, vancomycin. Patients were in hospitalized adult leukemia patients (Age >= 18 at the antibiotic dispensing date).

Monitoring Process
The data sources were pharmacy Centricity database and institutional enterprise data warehouse. Hyperion Interactive Reporting Studio 11 was used to query the weekly patient antibiotics usage and LOS from both data sources before and after intervention. The antibiotic therapy duration was based on the antibiotic dispensing starting date of the patient visit, and LOS was based on the admission starting date of the patient visit.

With selected time period, all antibiotic measurement indexes were calculated, the mean, upper control limit (UCL) and lower control limit (LCL) of each drug were generated and charted for the intervention statistical process control (SPC) chart (Fig. 1); Mean and median duration therapy and patient LOS chart was created for easy viewing (Fig. 2).
Visualizing Clinical Workflow using Time and Motion Data

Danny T.Y. Wu, MS¹, Nikolas Smart, MS², Sang-Jung Han, MS¹, Maria Majeed, MS¹, Jin Han, MS¹, Suinan Li, MS¹, Fan Zhang, MS¹, Kai Zheng, PhD¹, ²
¹School of Information; ²School of Public Health; University of Michigan, Ann Arbor, MI

Abstract

Understanding clinical workflow is crucial to improving quality, safety, and efficiency of patient care delivery. A common source of data for studying clinical workflow is through time and motion studies, which however generate multi-dimensional datasets that are very difficult to analyze. To address this challenge, we used three visualization techniques to visualize time and motion data to allow for easy identification of important workflow patterns. These visualizations help us better analyze physical movements, relationships between locations and activities, and the magnitude of change in workflow.

Introduction

Studying clinical workflow to detect deficiencies and optimize processes has great potential to improve quality, safety, and efficiency of patient care delivery. Clinical workflow is commonly characterized using data collected via time and motion observation, which has been a gold standard for quantitative workflow studies.¹ Because time and motion data contain many dimensions, such as locations, timestamps, activities, and roles, challenges remain in effectively analyzing such data to identify important workflow patterns. To address this challenge, we used three visualization techniques to explore potentially interesting clinical workflow patterns from a time and motion dataset that we collected in an ambulatory primary care practice. These visualizations were designed to allow for easier and more effective human inspection of patterns related to physical movements, relationships between locations and activities, and the magnitude of change in workflow.

Method

The dataset contained 68 observation sessions whereby independent human observers shadowed clinicians to collect time and motion data. Each session lasted 3.2 hours on average. The clinician participants included four providers, two nurses, one assistant and one receptionist. Their activities were categorized into three levels: task, category, and theme. Three visualization techniques were used to support the analysis of the data.

Results

Figures 1–3 show the three visualizations. Figure 1 is a path graph illustrating clinicians’ physical movements in the clinic. Figure 2 is a sequence sunburst chart illustrating the relationships between locations and activities. Figure 3 is a horizontal multi-bar chart illustrating the magnitude of workflow change between two calendar months in which the observations took place. We are currently using these visualizations to guide our analysis of important workflow patterns in the study clinic.

Conclusion

We implemented three visualization techniques to identify important workflow patterns in a time and motion dataset. The analysis is ongoing and the findings will be validated using other sources of workflow data collected from the same clinic.

Use of an Electronic Health Record as a Research Tool: Frequency of Exposure to Targeted Medical Conditions and Health Care Providers’ Clinical Proficiency

Tim Wysocki, PhD, Center for Healthcare Delivery Science, Nemours Children’s Clinic, Jacksonville FL
James Crutchfield, PhD, Mission Systems and Training, Lockheed Martin Corporation, Orlando, FL
Maria Carmen G. Diaz, MD, Division of Emergency Medicine, Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE
James P. Franciosi, MD, MSCE, Division of Gastroenterology, Hepatology and Nutrition, Nemours Children’s Hospital, Orlando, FL

INTRODUCTION: Pediatric medical care frequently requires complex decision making and nuanced judgments that tend to deteriorate over time if those skills are not used. Frequency of exposure to specific health care problems is known to be an important influence on maintenance or decay of health care providers’ clinical proficiency in managing those problems. The electronic health record (EHR) could be used to quantify frequency of exposure and to select clinical problems for study that provide opportunities to understand 1.) Whether health care providers’ clinical proficiency in managing a specific health condition tends to decay with increasing duration since the prior exposure to that condition; and 2.) Which characteristics of the work, the worker and the workplace affect the magnitude of decay in clinical proficiency. This study sought to demonstrate utility of the EHR in identifying and forecasting specific clinical skill domains in care for specific targeted medical conditions that may yield the greatest benefits in terms of quality and safety of care.

METHODS: This research was conducted at Nemours Children’s Health System in the Delaware Valley and Florida. The data reported here were obtained at the health care provider level in a completely de-identified, aggregated manner from Nemours EHR Data Warehouse for the most recent 2-year period. The criteria for selection of targeted clinical problems for further study were: high frequency of care encounters; varied types of providers; adequacy of EHR; variable frequency of exposure to that problem within providers; presence of evidence-based practice guidelines; variability in health care providers’ performance; controversy among experts about optimal management; and interest among clinical divisions to facilitate this research. Based on those criteria, the research team selected (from an initial list of 100 candidates) nine clinical problems for further study, including obesity, influenza vaccination, gastroesophageal reflux disease (GERD), concussion, supracondylar fracture, idiopathic scoliosis, headache, encopresis-constipation and type 1 diabetes mellitus. Health care providers, recognized within Nemours as having special expertise on each condition were recruited to serve as subject matter experts (SMEs) for a series of task analysis interviews, often supplemented with published practice guidelines, designed to define optimal clinical management of each problem and to specify EHR data elements that could quantify expression. The team developed a Δ-t statistic, time since the provider’s prior clinical encounter with the targeted clinical problem, as an index of frequency of exposure. The team also collected certain worker (e.g. health care provider demographics, time since prior board certification, EHR proficiency) and workplace (e.g. on-call schedule, clinic appointment density) variables from sources other than the EHR itself.

RESULTS: The nine clinical problems were evaluated across the Nemours healthcare system, using aggregated data from 2013. Encounter frequency ranged from 1566 cases of encopresis-constipation to 220,774 encounters for influenza vaccination. Mean Δ-t ranged from 1.72 days, for obesity, to 30.79 days for influenza vaccination. Based on the relatively low number of cases, encopresis-constipation appeared with the next highest value with a mean Δ-t of 23.25 days. Maximum Δ-t ranged from 285, for obesity to 497 for headaches. Obesity, influenza vaccination and GERD demonstrated a maximum Δ-t of somewhat less than a year, but the rest indicated greater than 400 days. Except for influenza vaccination, the distribution of Δ-t for each clinical condition fit a Gamma distribution (P < 0.001), indicating that the appearance of patients for each of these conditions follows a Poisson distribution. The distribution for influenza vaccination differed due to seasonality of administration, but still generally fit the distribution. Number of different clinicians seeing these conditions averaged 250, with Type 1 diabetes having the smallest number of different professionals, at 114.

DISCUSSION: This project demonstrates the utility of the EHR as a research tool in studies of quality and safety of care and specifically frequency of exposure of health care providers to specific health care problems. We believe that the use of the EHR to characterize frequency of exposure of health care providers to specific health care problems will allow health care organizations to be better prepared to identify intervention loci that can lead to improved quality and safety of care in a cost efficient manner. Subsequent steps in our research include building a multivariate model to enable prediction of clinical skill decay/maintenance and to test interventions focused on preventing decay of clinical knowledge and skills.
PheWAS Network Analysis and Visualization

Yaomin Xu, Todd Edwards, Lisa Bastarache, Rebecca Jerome, Shilin Zho, Eric S Torstenson, Wei-Qi Wei, Jana K Shirey-Rice, Erica Bowton, Yu Shyr, Jill M. Pulley, Joshua C. Denny
Vanderbilt University, Nashville, TN, USA

Abstract
Understanding the genetic determinants of complex diseases is essential in personalized genomic medicine. In this work, we will demonstrate an exploratory data analysis framework, integrating networks and statistical modeling techniques, to build a set of graphic representation and analysis strategies depicting complex associations between genetic architecture and disease risks. We will illustrate with a case study of our approach applied on a dataset from Vanderbilt EMR-linked biobank with 30,000 subjects and 1500 disease codes.

Introduction and background
In genetic association studies of complex diseases, we expect many genes affect each disease and each gene affects many diseases, and together they form a networked, many-to-many relationship that is challenging to characterize or make sensible inferences. Dense phenotypic data from a DNA biobank linked to Electronic Medical Records provide unique opportunities to unravel the complex disease genetic associations(1). Network modeling provides an effective technique to model complex data relationship as graphs and facilitate exploratory data analyses and data visualization(2). We aim to utilize the network modeling integrating genetic architecture and disease associations to characterize the complex 1) disease similarities and 2) gene-gene interactions from a phenome-wide association study (PheWAS).

Method
Assuming that disease risk varies among different sub-populations determined by genetic variants, we first characterize the gene-based genetic architecture using a coherent genetic network. Second, we calculate the risk profiles over the estimated genetic architecture. Third, we quantify the disease similarities and genetic interactions based on the correlation of the calculated risk profiles. Fourth, we model the disease similarity or gene-gene interaction using weighted networks. Finally, we analyze the network topology to identify the interesting disease genetic relationship such as coherent disease clusters of a given gene and genetic modules of a given disease. We model this against the PheWAS performed for variants predicted to confer risk to several autoimmune disease.

Results
Our approach assembles phenome-wide disease genetic associations into 1) a gene-centric disease networks that characterizes the relationship of diseases based on their risk patterns over the genetic networks, 2) a disease centric genetic networks that characterizes the gene-gene interactions based on risk profile among individuals, and 3) a gene-disease bipartite networks that characterizes many-to-many relationships of multiple disease with multiple genes. Specifically, in our association, the visualization allows data-up assembly and testing of haplotypes associated with disease.

Conclusion
In summary, we presented a novel network-based approach to facilitate PheWAS data visualization and analysis and help better understand complex disease genetic associations.

Simplified Spectrographic Display for Bedside Electrographic Seizure Detection in the ICU

Peter Z. Yan, M.D.1, Zachary Grinspan, M.D., M.S.2
1 Department of Neurology, New York-Presbyterian Hospital - Weill Cornell Medical Center, New York, NY
2 Center for Healthcare Informatics and Policy, Department of Healthcare Policy and Research - Division of Health Policy and Economy, Department of Pediatrics - Division of Child Neurology, Weill Cornell Medical College, New York, NY

INTRODUCTION: A seizure is a temporary dysfunction of the brain involving excessive synchronous neuronal discharge. A seizure lasting more than 5 minutes (status epilepticus) is life threatening. In ICUs, seizures are often non-convulsive (up to 1/3 of patients in neurologic ICUs), detectable only on EEG. Early treatment is key, as more than 80% of patients respond to treatment if it is initiated within 30 minutes, but less than 40% respond if treatment is delayed for two hours or longer. Mortality (33%-57%) can double if seizures are untreated after 24 hours.1 As such, continuous EEG (cEEG) is commonly used to identify seizures in medical or neurologic ICUs. However, this produces hours of EEG records to be read by a sub-specialized neurologist, who gives report to the ICU physician usually 1-3 times daily, a workflow which may delay treatment.2

A simplified seizure visualization display for bedside ICU physician could potentially reduce this delay. Current EEG visualization systems are primarily designed for the neurophysiologist; these systems are complicated and poorly suited for physicians without sub-specialized training.

METHODS: We applied two spectrographic variations to EEG data of 186 seizures from 24 pediatric patients: a median power spectrogram (MPS; a novel method) and a hemispheric asymmetry spectrogram (HAS; adapted from published research and commercial software.) MPS is less sensitive to artifacts and serves as a generalized seizure detector (figure 1). HAS serves as a simplified focal seizure detector (figure 2). In combination, we expect most seizures will appear in at least one of the spectrograms. Power spectograms were produced with short time Fourier transforms (hamming window, window length = 2s, FFT length = 212, 50% overlap). The median power of each frequency bin per minute was calculated for the median power spectrogram. The sum of the power on the left minus the right was calculated for the hemispheric asymmetry spectrogram. EEG data was acquired from the CHB-MIT scalp EEG database.3 All signal processing was performed with MATLAB. Spectrograms were qualitatively reviewed for harmonic resonance, or vertical “ripples”, indicative of electrographic seizures as well as other obvious changes from background.

RESULTS: One non-subspecialist (PY) identified 88% (162 of 186) of seizures in an initial non-blinded review. This is compared with published reports of 79-83% seizure detection involving traditional color density spectral array (CDSA) by non-subspecialists or certified neurophysiologists.4,5 Qualitative review of the EEG waveforms suggests that majority of missed seizures (14 of 186) consisted of slow delta seizures on the EEG.

CONCLUSIONS: Preliminarily, the combination of a median power and hemispheric asymmetry spectrogram detect seizures more frequently compared to CDSA in published reports. This raises the possibility that the MPS+HAS display will be easier to use and more sensitive in seizure detection when compared to current methods.

NEXT STEPS: A robust evaluation with multiple blinded readers is in progress, which will include estimates of sensitivity, specificity, and inter-interpreter variability. A new graphical user interface is also in development to facilitate review of the spectrograms. The eventual implementation will be integration into an ICU dashboard, such that electrographic, physiologic, and pharmacologic data will be displayed side by side in real time to assist the ICU physician with clinical decisions.

GeoHealth Informatics: Applying Geographic Information Science (GIS) to Support Heart Failure Self-Care

Nan Ye, M.S., Daniel Johnson, Ph.D., Richard J. Holden, Ph.D.
IUPUI, Indianapolis, IN

Research question
Patients with heart failure experience challenges performing daily self-care activities such as exercise, taking medications, monitoring for symptoms, diet, and less frequent activities such as attending appointments and managing medication supply. This study’s research question is, how can geographic information science and systems (GIS) facilitate heart failure self-care and mitigate self-care barriers?

Methods
Based on recent studies of heart failure self-care and secondary analyses of data from 61 older adults with heart failure, we identified common geospatial factors shaping self-care. We then identified opportunities for GIS to facilitate self-care through a combination of searches of: 1) existing software and devices with GIS functionalities and 2) literature on GIS applications to chronic illness self-care.

Results
Diet management was influenced by location in several ways, including the proximity of fast food restaurants and distance from sources for healthy foods. Being located in one’s home versus eating out affected diet, although this depended on patients’ circumstances such as the presence of a family member at home. Physical conditions such as weather and steep terrain, lack of nearby exercise facilities, and inadequate transportation affected patients’ ability to exercise or attend cardiac rehabilitation sessions. Distance from the pharmacy, pharmacy and clinic hours, and comfort driving were examples of geospatial factors influencing medication management. Various other geospatial barriers were identified; some (e.g., transportation) affected multiple self-care behaviors. Several existing GIS software applications and tools in the market can potentially assist heart failure self-care, e.g.:

- **On-demand transportation options** (e.g., Uber) could overcome distances and lack of personal vehicle
- **Wearable/personal devices** with GPS and other sensors can detect problems, connect patients to clinicians and caregivers, and provide feedback on entering a ‘geo-fenced’ area (e.g., vibrate near low-walkability street).
- **Food system maps** (e.g., [http://mdfoodsystemmap.org/map/](http://mdfoodsystemmap.org/map/)) can show food deserts and guide patients to healthy food resources or allow patients to recommend or rate local restaurants based on sodium content.
- **Geospatial data collected from a panel of patients** can inform clinicians of the challenges and resources that patients, individually and in groups, may encounter in their places of work, residence, and daily activity.

Conclusion
Barriers to and resources for heart failure self-care vary by physical-spatial, social-cultural, and organizational context. GIS technology can help patients better understand, organize, and access resources to make informed self-care decisions and overcome self-care barriers. This poster will demonstrate opportunities for GIS to improve health and disease management by leveraging GIS tools to help patients with chronic disease bridge specific self-care gaps. Challenges to be discussed include device cost, tool usability issues, patient privacy, uncertainty about patient behavior and self-care adherence from GIS data, the need for resources specific to older patients and patients with heart failure, and issues related to caregiver support. We argue for developing what we call GeoHealth Informatics, an area that crosses health informatics with health geography to support better health and disease management.

Intelligence in Usability Survey Research (iUSuR): an Online Usability Question Bank for Usability Survey Research

Po-Yin Yen, RN, PhD¹, Nima Esmaili Mokaram, BS², Gina Torelli, BS³, Alissa Schultz, RN, MA, MS¹,⁴, Xiaonan Ji, MS¹,²
¹Dept of Biomedical Informatics, ²Dept of Computer Science & Engineering, ³Dept of Industrial Engineering, ⁴College of Nursing, The Ohio State University, Columbus, OH

Abstract
Because of low cost and easy administration, usability survey research is commonly used to evaluate health information technology (HIT) for general user satisfaction or technology acceptance. However, support and resources for usability survey research are limited. We created an online usability question bank to help researchers search and select appropriate instruments for their HIT usability survey research.

Introduction
Usability survey research uses survey instruments (aka questionnaires, scales, or surveys) to evaluate HIT. Numerous survey instruments have been developed and validated. However, these survey instruments are often changed or manipulated.¹ It is common for researchers to create new and/or modify existing instruments, because of missing or dissimilar interpretation of usability concepts from existing surveys, or lack of awareness of current, validated instruments. We collected validated questionnaires for technology evaluation and developed an online usability question bank, Intelligence in Usability Survey Research (iUSuR)² to assist researchers conducting usability survey research.

Methods
Currently, iUSuR contains 246 questionnaires consisting of 6970 individual questions. We established a database using MySQL, storing information of entity, referential, and domain integrity constraints, and set up a database driven web application using PHP and CodeIgniter Framework. The application uses object-oriented and component-based structure with model-view-controller (MVC) architecture pattern to organize and present the website. We stored three types of data from each survey instrument: 1) full citation - including author(s), year, title, journal, and cited count; 2) usability concepts measured, validation methods and types, full questions, and answer types; 3) advanced features to have individual questions tagged with usability taxonomy, to enhance the categorization. These advanced features also enable searching across the survey instruments, to identify physical features, personal interactions, task performance, organizational roles, personal characteristics and intention to use.³

Results
iUSuR allows researchers to browse and select existing survey instruments, or aggregate questions from multiple instruments as needed (Figure 1). When used as a collaborative tool, iUSuR’s analytic system tracks usage data on all survey instruments. Each time a user selects and/or modifies a survey questionnaire or question, it automatically returns anonymous usage data to the question bank. Users can base their decision on the usage data to justify selection of an original or modified question or, secondary modification of the question for their individual study needs.

Conclusion
iUSuR is an inventory of usability survey instruments as well as a collaborative site for researchers. Future plans include the implementation of an expert system to provide usability concept recommendations; thus assisting low cost, efficient, and effective HIT usability survey research.

Annotating Recommendation Sentences in Radiology Reports

Meliha Yetisgen, PhD1,2, Prescott Klassen, MS2, Lucas H. McCarthy, MD3,1, Tom H. Payne, MD4, Martin L. Gunn, MB ChB5

1Biomedical and Health Informatics, 2Department of Linguistics, 3Department of Neurology, 4Information Technology Services, 5Department of Radiology, University of Washington, Seattle, WA

Abstract

Communication of follow-up recommendations when abnormalities are identified on imaging studies is prone to error. The absence of an automated system to identify and track radiology recommendations is an important barrier to ensuring timely follow-up of patients especially with non-acute incidental findings on imaging studies. We are in the process of building a natural language processing system to identify clinically important follow-up recommendations in free-text radiology reports so that the reports can be flagged and separate workflow processes can be initiated to improve the consistency and quality of care delivery. To accomplish this, we are creating a multi-institutional radiology report corpus annotated for clinically important recommendation information.

Dataset

We created a large-scale radiology report corpus containing 745,058 reports from three different institutions including Harborview Medical Center, University of Washington Medical Center, and Seattle Cancer Care Alliance. The corpus covers a range of imaging modalities, including radiographs, computed tomography, ultrasound, and magnetic resonance imaging.

Annotation Process

We define recommendation as a statement made by the radiologist in a given radiology report to advise the referring clinician to further evaluate an imaging finding by either other tests or further imaging. When we analyzed our corpus, we observed that there are various different types of recommendation mentions in radiology reports. Based on this analysis, we grouped the recommendations under the following four categories; (1) Non-contingent clinically important recommendation (e.g., CT chest is recommended to further evaluate the lung mass.), (2) Contingent clinically important recommendation (e.g., If this breast lesion has not been previously evaluated, recommend referral to the breast service for further evaluation), (3) Clinically important recommendation likely reported (e.g., L distal radius fracture x 1 week, please also follow-up to rule out scaphoid fracture compared with last week's x-rays), (4) Clinically unimportant recommendation (e.g., Consider an MRI of the forearm if diagnostic certainty is desired).

Using the BRAT rapid annotation tool, two clinical experts annotate the boundaries of recommendation sentences and assign each annotated sentence to one of the four categories. Because manual annotation is a time-consuming and labor intensive process, we can only annotate a small portion of our large radiology report corpus. To make the process faster, we use a semi-automatic annotation approach where we train an initial statistical classifier on a small set of labeled examples we created for preliminary work. By manipulating the configuration of the classifier, we build a very high recall (90.18%) but low precision model (35.07%). Details of this seed dataset and classification approach can be found in [1]. We run this model on a randomly selected set of reports from our un-annotated corpus and present the annotators only reports that include recommendation sentences identified by the model. The annotators read the complete reports to correct system-generated annotations or add new annotations.

Conclusion

Our two expert annotators annotated 50 reports for recommendation sentences. The interrater agreement on the first set of 50 reports is Kappa 0.43 and an F1-score of 0.59. One of the main reasons for these low agreement scores, is the subtle differences in the perception of importance of recommendation sentences by the annotators as they assign categories. To resolve the disagreements, we scheduled multiple meetings. The annotators completed the annotation of 567 radiology reports using updated guidelines based on inter-annotator agreement stage. They highlighted 265 sentences as category 1, 90 sentences as category 2, 222 sentences as category 3, and 160 sentences as category 4.

Anchor time extraction for building timeline from Korean clinical narratives

Wangjin Yi¹, Seongkeun Park, MD. Ph.D² and Jinwook Choi, MD. Ph.D²,*
¹Interdisciplinary program in Bioengineering, Graduate School, Seoul National University; ²Department of Biomedical Engineering, College of Medicine, Seoul National University

Introduction: To build a timeline extraction and visualization system¹ for Korean clinical narratives this research focuses on recognizing the anchor time as the first part of whole system. A clinical narrative contains valuable information on a patient’s progress of a disease. However, it is hard to efficiently extract information on Korean narratives since free word order of the language makes its expressions complex to be processed.

Anchor Time Extraction using Conditional Random Fields: An anchor time presents one or more events with a group on a certain point in a timeline, and provides clues for following the progression of a patient’s history. We define the two types of anchor times as points (date, time) and intervals written as time expressions. Since they are morphologically similar to lab values, to distinguish them precisely, we formulate the task of extracting anchor time as a sequence labeling. One of the most popular sequencing model, Conditional Random Fields (CRF)², is used to enhance contextual label structure. The best performance in a similar task (i2b2 2012) is F1 of 0.91³ by using CRF.

Tokenization by letter types: In most cases, two or more distinct tokens are in a singleton term in our corpus (e.g., number + Korean). Since the features in the CRF are based on tokens, we additionally tokenize singleton terms by letter types to achieve better generalization.

Feature extraction: Features used in this research are grouped as three types; 1) morphological features (Korean morphemes of the current token), 2) dictionary features (Temporal noun lists, modifiers around temporal expressions), 3) contextual features (token context within window size 3, the occurrence of white spaces)

Experimental Results: We randomly selected 600 discharge summaries of patients, who admitted for any chief complaints and discharged in January 2013, from the electronic health record system of the Seoul National University Hospital. The collection was divided to three distinct sets and we tested the CRF extraction system on each set. Based on exact matching, the performance was evaluated by Precision (P), Recall (R), and F1 (F) with 10-fold cross validation for each set. The performance on the set is 0.897 (P), 0.831 (R), and 0.862 (F) (averaged value). For performance validation, we additionally used a different kind of narratives and same kind but written at different time; 1) 200 admission notes of patients who discharged in January 2013, 2) 200 discharge summaries of patients discharged in 2003. Especially, clinical narratives written in 2003 were created right after the adoption of the EHR in the hospital, and contained writing errors making them noisy for processing. The performance on the admission notes in 2013 is 0.922 (P), 0.856 (R), and 0.888 (F). And the performance on the discharge summaries in 2003 is 0.946 (P), 0.893 (R), 0.919 (F). They are achieved when we use 2nd order CRF.

To evaluate the effectiveness of the tokenization method, we compared the performances of the extraction systems trained on each text set tokenized by white space and letter types for both set of discharge summaries. We confirmed overall improvement in F1 when the extra tokenization was applied (+0.196, +0.129 for 2013 and 2003 respectively).

Limitation: This research performed on a small set of clinical narratives created in a single institution. However, to overcome this limitation we gathered various kinds of narratives and tested on multiple settings.

Conclusion: To recognize anchor time from Korean clinical notes a CRF extraction system was used and it is highly effective based on a text tokenized by letter types. And the model is more effective when the test sets are noisy.

Annotation of Disease Characteristics for Cancer Liver Stage Prediction

Wen-wai Yim¹, Sharon W. Kwan, MD², Guy Johnson, MD, PharmD²
Meliha Yetisgen, PhD¹,³
¹Biomedical and Health Informatics, ²Department of Radiology, ³Department of Linguistics, University of Washington, Seattle, WA

Abstract
Liver cancer is one of the leading cancer-related causes of death worldwide that occurs across different lifestyle and genetic environments. Despite availability of many new treatments, deaths due to liver cancer have increased in the United States even as those of other cancers have decreased and more than 80% of patients in all stages do not survive past 5 years. To facilitate evidence-based research in liver cancer, we (a) define a set of domain-related characteristics to annotate, (b) construct a workflow to support annotations at several levels, and (c) evaluate the consistency of our annotation scheme through a double annotation experiment. In this abstract, we describe our annotation process, as well as our inter-annotator agreement for our task.

Introduction
Liver cancer is a deadly disease with only a 17% 5-year survival rate across all stages, which occurs over different lifestyle and genetic environments. In the United States, liver cancer incidences are projected to increase with larger contributions of obesity-related cases. Because the liver is a vital organ involved in multiple roles, liver cancer often occurs along with other liver problems such as cirrhosis. Therefore, there are many competing risks of mortality that affect treatment options. To determine the best treatments given certain patient characteristics, a large diverse dataset must be collected and reviewed. However, the process of manual chart review is time-consuming and expensive. In order to build an automatic system of liver cancer stage extraction, we annotated a cohort of patients from the University of Washington Medical Center for liver cancer disease characteristics. To do this, our clinical experts first identified 14 parameters to annotate and created annotation guidelines for marking up clinical documents at both a text-span and patient level. After constructing our annotation workflow, we tested inter-annotator agreement on a sample of 20 patients.

Annotation
Our domain experts identified a set of 11 entity categories along with specific values each can take on for text-span annotation: (1) ascites—accumulation of fluid in peritoneal cavity (e.g., “no significant ascites”) with values (None, Mild, Moderate-Severe), (2) Child-Pugh—a measurement of liver cirrhosis (e.g., “Child’s B”) with values (A,B,C), (3) ECOG (Eastern Cooperative Oncology Group) Performance Status—a scaled measure of general well-being (e.g., “ECOG 0”) with values (0,1,2,>=3), (4) Extrahepatic Invasion—spread of cancer outside of the liver (e.g., “No evidence of extrahepatic extension”) with values (No, Yes), and several other entities. In some cases, non-explicit text evidence was highlighted (e.g. Ascites: None, “no free fluid in abdomen”). Patients not meeting cohort criteria were also identified for removal during annotation. Annotated report types included a variety of clinical notes (e.g. admit, interventional radiology, surgery), as well as CT or MRI abdomen radiology reports. Each liver cancer entity also had a corresponding patient level annotation to resolve possible conflicting information represented in different text-spans annotated for the same entity. In addition, BCLC (Barcelona Clinic Liver Cancer), CLIP (Cancer of the Liver Italian Program), and AJCC (American Joint Committee on Cancer) liver cancer stages were annotated at the patient level. Annotations for text-span and patient level labeling were performed using brat, a web-based annotation software, and an in-house python user interface software, respectively. Two annotators, both interventional radiology attending physicians, annotated text-spans for the 11 entities in the clinical notes of 20 patients. Afterwards, patient level annotations were annotated by the consensus of the two annotators. Of the 20 patients 3 were excluded due to irrelevant diagnosis. Inter-rater agreement showed an entity micro f1-measure of 0.910 at the patient level, 0.854 at the document level and 0.729 at the partial text-span level.

Future Work
We are in the process of annotating a 236-patient corpus to build an automatic liver cancer stage predictor. However, our methods may be useful for other types of cancer prediction, clinical cohort selection, and medical concept recognitions systems.

Predicting Autonomy for Physical Activity using Data Mining Techniques
Sunmoo Yoon, RN, PhD1, Niurka Suero-Tejeda, MS, MA1, Suzanne Bakken, RN, PhD1,2
1School of Nursing, 2Dept. of Biomedical Informatics, Columbia University, NYC, NY

Abstract
We applied data mining techniques to a community-based behavioral dataset to develop prediction models for gaining insights for a social media-based intervention for an urban underserved population. Environmental and modifiable personal factors influenced both positive intrinsic motivation ‘willing to make time for physical activity’ and negative intrinsic motivation ‘hard to make time for physical activity’. Data mining methods were useful to build physical activity prediction models prior to designing self-management interventions.

Introduction
Lack of physical activity poses a serious health threat to racial and ethnic minorities. In a previous study, we found that autonomy (‘willingness to make time’) influenced achievement of physical activity goals. The Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research (WICER) project aims to build an infrastructure to understand health behaviors to improve the health among an urban underserved population. Twenty-eight percent of those who completed the WICER survey reported use of social media. Consequently, social media has the potential to be an interventional platform for promoting physical activity. To examine this potential, this study aimed to develop prediction models for autonomy for physical activity by applying data mining techniques.

Methods
We extracted data on the sample participated behavioral survey (n=5,653) from the WICER research data warehouse using the REDCap. 122 behavior variables were iteratively selected from 945 variables by a domain expert (SY). 106 variables were further selected after applying M99.0 algorithm to remove useless attributes. Six unique variables were selected using CFS attribute evaluator1 to discover variables that were strongly related to physical activity. We applied a classification algorithm (J48) to iteratively generate models with random 10-fold validation. We selected final models based on predictive ability and clinical meaningfulness of variables.

Results
Environment factors (having place for exercise, and availability of fresh fruits and vegetables in the neighborhood) and personal modifiable factors (computer time and perceived weight) were the main predictors of willing to make time for physical activity (accuracy 74%, AUC=.72). Those with having place for exercise were more likely to willing to make time for physical activity. Among those with having no place for exercise, having fresh fruits and vegetables in their neighbor, perceived weight as normal and computer use ≤5hours/day was associated with increased likelihood of willing to make time for physical activity (Figure 1). Factors influencing negative motivation included cost barrier for exercise, self-confidence of work ability (score 1-5), and the social behavior of attending meetings (accuracy 65%, AUC=.66%). Participants with cost barrier and self-confidence score of work ability ≤3 were more likely to have negative motivation (Figure 1).

Conclusion
Data mining methods were useful for domain experts to build prediction models for autonomy of physical activity.

Using TURF Framework to Improve EHR-CPOE Medication Dosing in Renal Impaired Elderly

Rafeek A. Yusuf, MBBS¹, Mandana Salimi, BS¹, Min Zhu, PhD, MD¹
¹The University of Texas Health Science Center at Houston, School of Biomedical Informatics, Houston, TX

Introduction

Older adults (age>65 years) will account for 20% of the United States population by 2030. In older adults, renal impairment is evident due to decreased glomerular filtration rate, renal tubular function, and creatinine clearance¹. In 2011, the United States spent $49.3B on End Stage Renal Disease (ESRD) programs. Some studies show the positive impact of Computerized Physician Order entry (CPOE) in reducing mortality rate. Studies have revealed the necessity of adjusting the dosage of medications in the presence of renal insufficiency. If it is not adjusted, patients' lives may be put at risk. CPOE supports electronic ordering of medications. However, CPOE with poor user interface may result in technology-induced errors and pose risks to patients. As such, it is important to evaluate the usability of CPOE user interfaces, identify potential issues, and based on well-established framework, design new interfaces that address identified gaps.

Methods

First, the authors evaluated an existing EHR-CPOE module used for prescribing for older adults with renal impairment. Evaluation for usability issues was performed both electronically and manually using: (1) Usability heuristics, (2) User testing, and (3) System Usability Scale (SUS). Second, the authors used TURF framework² to analyze and redesign the existing EHR-CPOE interface, then developed a prototype with a graphical software. Finally, both existing and redesigned interfaces were evaluated for efficiency using the Keystroke Level Model-Goals, Operators, Methods, and Selection (KLM-GOMS) method.

Results

The existing EHR revealed poor usability and learnability. 11 violations of 6 types were noted; average severity rating of these problems was 3 (i.e. major violation); and SUS score was 10. For example, there were too many objects and related objects were not placed properly on the existing interface. The redesigned interface was less cluttered and related objects placed in close proximity. 25 steps were involved using existing versus 7 for redesigned EHR-CPOE module. Redesigned solution took 16.92 seconds versus 61.77 seconds for existing module to prescribe. Frequency distribution of KLM operators utilized in the existing versus redesigned solution of the EHR-CPOE module are shown in the bar graph below (see figure 1).

Conclusion

Use of evidence-based heuristics for evaluation of optimal EHR user interface design requires testing under realistic conditions. Usability testing can be used to demonstrate association between different usability problems and specific medical errors.

![Figure 1. Bar graph comparing KLM-GOMS operators between existing and redesigned EHR-CPOE.](image_url)

Hochheiser, PhD6, Charlene Weir, PhD7, Kristin Bell, MD5, Mark T. Gabuzda, MD4, Neil Farber, MD1, Braj Pandey, MD1,2, Alan Calvitti, PhD2, Lin Liu, PhD1, Richard Street, PhD9,10,11, Zia Agha, MD1,2,4

1University of California, San Diego, San Diego, CA; 2Veterans Medical Research Foundation, VASDHS, USA; 3University of California, Irvine, Irvine, CA; 4West Health Institute, La Jolla, CA; 5University of Michigan, Ann Arbor, Michigan; 6University of Pittsburgh, Pittsburgh, PA; 7University of Utah, Salt Lake City, Utah; 8VA San Diego Healthcare System, San Diego; 9Texas A&M University, College Station, TX; 10Baylor College of Medicine, Houston, TX; 11Houston VA Center for Innovations in Quality, Effectiveness and Safety

Introduction

While EHR systems can improve the efficiency and quality of clinical practice, the use of EHRs is commonly associated with increased workload such as prolonged documentation time and new types of documentation tasks1, resulting in end user frustration. Nonetheless, few studies have examined what accounts for the extra workload. This work aims to understand the sources of the extra workload brought upon by the use of EHRs. Doing so, we hope to provide sociotechnical solutions that can alleviate the increasing workload faced by healthcare providers.

Materials and Methods

Semi-structured interviews were conducted with 14 physicians at the VA San Diego Healthcare system. Interview questions were aimed at understanding how physicians use EHRs before, during and after clinical encounters. We used affinity diagram, a common method in qualitative studies, to analyze the interview data2.

Results and Discussion

The analysis shows that the use of EHRs led to extra work for physicians. Most physicians complained that they now spend more time during and outside of visits to catch up on EHR-associated tasks. We categorize the sources of the extra workload into the following categories: 1) Poor usability. Physicians have to perform many clicks to enter orders, and also have to manually enter information for medication lists, which can be time consuming. 2) New tasks enabled by EHRs, such as how there are an overwhelming amount of clinical reminders built in the systems that require physicians to review and approve. 3) Changed work responsibilities. The convenience of EHRs resulted in new work responsibilities for physicians, such as how primary care physicians now have to serve as cosigners for a variety of tasks in the EHRs. 4) Administrative tasks. EHR systems have various quality assurance and administrative functions built in, which require extensive documentations by the physicians. More analysis is needed to evaluate the new tasks imposed on healthcare providers, and to carefully redesign the work responsibility, the functionality and usability of the EHR systems. As part of a larger study, we plan to recruit more participants to increase sample size. We also plan to analyze the collected video-recorded EHR activities and medical visits to further understand the sources and impact of the extra work.

Predicting Future Anxiety and Depression Diagnoses among College Students Utilizing Electronic Health Data

Jinghe Zhang, MS, Hao Wu, MS, Adrienne Keller, PhD, James Turner, MD, Laura E. Barnes, PhD
University of Virginia, Charlottesville, VA

Introduction
College students responding to the Spring 2014 American College Health Association-National College Health Assessment reported feeling things were hopeless (46%), felt overwhelming anxiety (54%) and more than 80% reported feeling overwhelmed by all they had to do (86%). This critical subpopulation of Americans is facing significant levels of mental health problems, challenging colleges to provide accessible and high quality behavioral health care. However, psychiatric disorders are frequently unrecognized in primary care settings, posing physical, emotional, economic, and social burdens to patients and others. Toward the goal of earlier identification and treatment, we developed and evaluated predictive models that use electronic health record (EHR) data for predicting the diagnoses of anxiety and depression.

Methods
We used anonymous/de-identified archival EHR data collected between Jan 1st, 2011 to Dec 31st, 2014 to develop computational models for predicting anxiety and depression. Our dataset contained 182,845 distinct female patients in the control group (without any mental health diagnoses) and 14,417 patients in the target group (with an anxiety and/or depression diagnosis). Data consist of structured ICD-9 diagnosis codes and demographic data from 9 universities. The ICD-9 codes are aggregated into 283 clusters according to the AHRQ Clinical Classifications Software. We extracted the visit history of patients before their first diagnosis of anxiety/depression in the target group. By selecting patients with at least three visits, there are 88,247 female patients in the control group and 3,553 females in the target group. 80 diagnostic groups are selected using information gain according to their predictive capability of anxiety/depression. Of the selected diagnoses features, “viral infection”, “medical examination/evaluation”, and “immunization and screening for infectious disease” are much more prevalent among patients without mental disorders, while “thyroid disorders”, “headache (including migraine)”, “malaise and fatigue” appears much more frequently among patients diagnosed with anxiety or depression in their later visits.

Instead of traditional predictive models that work well for the average patients, we adopted the idea of personalized prediction according to case based-reasoning where a new problem is solved based on the solutions of other similar past problems. In this research, we computed the pairwise similarity between patients using Jaccard similarity index which captures the occurrences of clinical events in one’s medical history. Three classifiers are built to perform prediction on a patient’s clinical outcome. Model A: K-nearest-neighbors (KNN) with majority voting; Model B: weighted KNN which compares the sums of similarity scores between similar patients and the new patient; Model C: nearest centroid method, in which the centroid is the patient most similar to all other patients in the same class on average and the new patient is assigned the label of the class whose centroid is the closest to this patient.

Results and Conclusions
In our analyses, 3,500 patients are randomly sampled from each group to eliminate the impact of class imbalance. All the classifiers are trained and tested using 10-fold cross validation. The values of k in KNN models are [1, 5, 9, 13, 17, 21]. The performances of those models are evaluated using accuracy, sensitivity, positive predictive value, specificity, and negative predictive value. Model A and B achieve comparable performance with little difference. Overall, the optimal classifier is the weighted KNN when k is 20 and achieving an overall accuracy of 66.3%, a positive predictive value of 69.9%, and a recall of 57.4%.

The developed models could be used to aid clinicians in identifying patients at a high risk of anxiety and depression. However, one limitation is that visits are treated as unordered sets without consideration of potentially important sequential information. Future work will consider sequential modeling approaches. The granularity of the EHR data is another limitation of the current work in terms of its relevancy to anxiety/depression as well as how clinicians use this information to make diagnoses. Practical tools supported by the algorithms in this research could be developed to help students understand their risk of anxiety or depression according to their medical history.

Evaluating Efficient Clinician Utilization of Electronic Health Records

Yongkang Zhang, MS¹, Marie Krousel-Wood, MD MSPH¹,², Richard V. Milani, MD²,
Allison B. McCoy, PhD¹,²
¹Tulane University, ²Ochsner Health System, New Orleans, LA

Introduction

Hospitals and other health care providers are putting increased efforts into efficient utilization of electronic health records (EHRs) due to their potential to improve health care quality and safety. Analyzing the actual utilization of EHRs by clinicians therefore is of considerable importance to improve the adoption of EHRs. While prior work has evaluated clinician-reported EHR utilization, studies based on data directly from the EHR about clinicians’ behaviors, which may present stronger evidence, have not been reported.

Methods

We performed this study at a not-for-profit academic health system in southeast Louisiana consisting of 8 hospitals and over 38 health centers in urban and rural settings. Recently, clinicians began using a comprehensive, commercial EHR (Epic 2010, Madison, WI) in both inpatient and ambulatory settings after having used a basic, locally-developed EHR for more than a decade. We analyzed twelve measures of utilization of the new EHR system in four categories, including patient information review, timely completion of activities, order set use, problem list use, and preference list use. These variables were defined as key functionalities by the EHR vendor to be used to assess clinicians’ utilization of EHR. Data were directly extracted from the EHR’s clinical data warehouse. We used descriptive analysis to show the variability of efficient EHR utilization and linear regression analysis to test the clinician characteristics associated with EHR utilization. Analyses were conducted with Stata 13.0.

Result

Data were analyzed for 287 clinicians, consisting of 39,421 encounters during a one month time period, approximately six months after the health system implemented the new EHR. Data show variability in efficient EHR utilization among clinicians. Clinicians highly used the EHR to review the patient information. More than 75% of encounters’ medications, patient history, allergies and problem list were marked as reviewed by clinicians respectively. Clinicians also used the EHR frequently to complete activities in a timely manner. We found that 72.30% of the results-related messages were reviewed in less than 12 hours from being received and 55.41% of patient call messages were reviewed in less than 24 hours. Further, 64.22% of encounters were closed on the same day. Clinicians entered 40.11% of encounters diagnoses onto the problem list, and 69.88% of orders were placed from a preference list. However, the use of order sets was low among physicians. We found that merely 6.65% of orders were placed from an order set, and an order set was used in only 4.66% of closed encounters for face-to-face visits. Low order set utilization is expected, as order sets are designed for inpatient admission orders and not ideal for outpatient visits. We found the utilization of the EHR was associated with several clinician characteristics. Generally, clinicians working in inpatient setting were less likely to use features analyzed in this study compared to those working in outpatient settings. Primary care clinicians were more likely to use these features compared to medical and surgical specialty clinicians. Clinician age was significantly associated with use of order sets in closed encounters for face-to-face visits; we found that younger clinicians were more likely to use order sets compared to older clinicians.

Conclusion

Clinicians showed variability with respect to efficient EHR use. The EHR was highly used for data access and reviewing messages in a timely manner. Some of the frequently used features are related to Meaningful Use incentives. Order sets were seldom used among clinicians, which may be related to local configuration or training. Clinicians’ individual characteristics are related to the efficient EHR use. Further research is warranted and underway to evaluate the implications of efficient EHR utilization on clinician satisfaction and patient outcomes.
Social Media and Autism Support: Health Information Seeking in Facebook by Autism Patients and Caregivers

Yuehua Zhao, MS¹, Priya Nambisan, PhD²
¹School of Information studies, University of Wisconsin -Milwaukee; ²College of Health Sciences, University of Wisconsin - Milwaukee

Background and Significance
The online communities on social media sites provide an efficient platform to autism patients and their caregivers where they can ask for help and advice from other users, make contributions to others, receive assistance from the group members, and share their experiences in the community. In this study, we specifically focus on what kinds of information is being exchanged in an Autism Facebook group and we will classify them into various categories.

Method
We collected data and we are in the process of analyzing the posts from one of the largest Facebook group focused on autism. In total, 17389 group posts and comments ranged from April 2009 to March 2015 were collected by NVivo 10 and NCapture. Content analysis methods is being employed to evaluate the kinds of information users share in this group. This study will address two research questions: 1) what are the characteristics of the autism group on Facebook? 2) What types of information do users share and exchange within the online group?

Results
From April 2009 to March 2015, there were 7709 initial messages posted by 1395 unique group members in autism group, and 9679 messages replied by 1679 users. The average number of comments and likes for each post is 1.26 and 3.03, respectively, which demonstrated the active interaction and strong enthusiasm within the groups. Based on the statistics, users preferred to express their favor of the posts rather than making comments on others’ messages. The potential reason could be the ease of pressing the “Like” button for users when they saw interesting messages posted on the group wall.

All the posts and comments were then imported to SPSS Text Analytics for Surveys software. In total, 15031 records were processed by the natural language processing tools and eventually classified into 9 topics by manual revisions and modifications through data coding analysis: (1) parenting (2513); (2) social support (2245); (3) education (999); (4) research (588); (5) symptom (709); (6) career development (852); (7) therapy (153); (8) relevant diseases (921); (9) daily life (609).

It is not surprising that parenting issues come up frequently, because autism commonly appears in the first 3 years of life and parents usually trying to cope with the stressful situation were seeking help and support from the Facebook group. Given that one of core features of autism patients is difficulty with social interactions and communication, autistic children often face learning disorders. Therefore, education is a popular topic in this group., 999 messages pertained to education, including special education programs, training skills, tutors, etc.

The “relevant diseases” category had 921 posts and comments from group members and carried 10% weight among the record set. The nature of autism and the fact that is one of a spectrum of pervasive developmental disorders probably contributed to this - a lot of posts inquired about the difference between several different but relevant diseases, such as asperger syndrome, pervasive developmental disorder - not otherwise specified (PDD-NOS) and childhood disintegrative disorders.

Conclusions
Facebook group has been used as an efficient platform by autistic patients and their family members. The group was very active and members provided strong support to each other. The topics discussed by group members reflected users’ concerns about autism. Through the coding analysis, this study did a first level classification of topics discussed in this group and our findings show that autism is chronic disease users were more concerned about dealing with it in their day-to day life than the medical aspects of it.
Understanding the Use of Adverse Events Criteria in Radiation Therapy: A Literature Mining Approach

Yi Zhen¹, MS, Yuliang Jiang², MD, Jackie Wu³, PhD, Lulin Yuan³, PhD, Yaorong Ge¹, PhD
¹Department of Software and Information Systems, University of North Carolina at Charlotte, Charlotte, NC
²Department of Radiation Oncology, Peking University 3rd Hospital, Beijing, China
³Department of Radiation Oncology, Duke University Medical Center, Durham, NC

Introduction

Accurate scoring and reporting of adverse events in radiation therapy are important for radiation toxicity monitoring and treatment quality improvement. Standardized criteria for scoring adverse events after radiation therapy facilitate normalized evaluation and reporting terms of adverse events and allow accurate analysis of toxicity results at large scale and across multiple studies. Three of the most commonly used criteria RT clinical studies are the Common Terminology Criteria for Adverse Events (CTCAE), the Radiation Therapy Oncology Group (RTOG), and the Late Effect Normal Tissue Task Force (LENT)/subjective, objective, management, analytic (SOMA). These standards have been revised multiple times in recent years. In particular, CTCAE is strongly promoted as the standard for adverse event reporting. However, there is a lack of studies to understand how the various standards have been used in RT clinical studies. This project aims to develop a text mining based method for investigating the usage trend of the three most commonly used adverse events criteria in published literature. In this report, we will address three specific questions: (1) the portion of studies that use each standard; (2) the trend of usage in recent years; (3) the types of adverse events that are reported by each standard.

Methods

We analyzed 531 published articles from January 2010 to December 2012. A total of 668 articles were found in MEDLINE with a search strategy that organized the search terms in following three groups: “radiotherapy, chemoradiotherapy, brachytherapy”, “toxicity, side effect, adverse event, adverse reaction, complication”, and “CTC/CTCAE or LENT-SOMA or RTOG, RTOG/EORTC”. We exclude 104 articles due to inadequate information, and 33 duplicated articles. All selected full articles were downloaded and extracted into text files for analysis. The basic workflow of our project consisted of data preprocessing, statistics calculation, and classifier modeling. We separately used regular expression and Naïve Bayes Classifier to categorize these 531 published articles based on the adverse events criteria applied. In parallel, a radiation oncology physician reviewed all the articles and produced the usage trending data manually. Finally, the manual results were used as a gold standard to assess the text mining results using both approaches.

Results

Based on regular expression analysis, we identified 320 articles using CTCAE, 311 articles using RTOG, 49 using the LENT-SOMA, and 140 using a combination of two or three criteria. From the Naïve Bayes Classifier, we found 340 article using CTCAE, 303 articles using RTOG, 28 using the LENT-SOMA, and 180 using two or more criteria. Compared to the results labeled by the domain expert, the results from the regular expression method reported comparable counts and similar overall usage trends. The results from the Naïve Bayes classifier are also similar to that of the domain expert’s, however the usage trends for the combined-criteria group was over-estimated. As seen in the results, the CTCAE is becoming the most commonly used criteria over time. And RTOG is the most used criteria in 2010, but since 2012 CTCAE has taken over as the most frequently used criteria. We notice that lung cancer studies heavily favor CTCAE while the head and neck cancer studies seem to favor the RTOG standard. We also notice that prostate cancer contributed most radiation therapy articles in the study period while the rectal cancer has least number of studies.

Conclusion

The text mining method based on regular expression is effective in identifying the use of various standard adverse events criteria in RT clinical studies. The analysis shows increased use of CTCAE overall and especially in lung cancer, but also continued use of RTOG in head and neck cancer studies.
Medication Adherence to Oral Hypoglycemic Agents and Hospitalization Cost in Medicaid Patients with Type 2 Diabetes

1Vivienne J. Zhu, MD.,MS. 1Wanzhu Tu, Ph.D, 1Marc B. Roseman, 2J. Marc Overhage MD.,PhD.
1Regenstrief Institute, Inc. Indianapolis, Indiana and 2Cerner, Malvern, PA

Objective: Medication adherence is a major factor impacting patient health outcome and utilizations. Using real world clinical data, we analyzed the correlation between medication adherence to oral hypoglycemic agents (OHA) and the cost of hospitalization related to type 2 diabetes (DM2).

Methods: A sample of Medicaid patients with DM2 who had OHA dispensing records between January 1, 2001 and December 31, 2008 was identified in the Indiana Network for Patient Care (INPC). OHA adherence was measured by the proportion of days covered (PDC) in every 6-month interval starting from the patient’s first OHA dispensing event and further dichotomized using a conventional cut-off point (0.8). The relationship of OHA adherence to healthcare cost during the subsequent six month interval was examined. Healthcare cost included cost of DM2 related hospitalizations and OHA medication expenses under the Medicaid coverage. Mixed effects linear models with repeated measures were used for analyses. Selected patient demographic and clinical factors were included to control the possible confounders.

Results: Among 8,889 eligible patients, 8,288 were OHA non-adherent patients (67.8% female, 76.2% white and mean age of DM2 onset 45.5 years) and 601 were OHA adherent patients (62.6% female, 84.3% white and mean age of DM2 onset 49.4 years). In the non-adherent group, the mean OHA medication expense was $62 and 2,856 (34.5%) patients had at least one hospitalization with an average cost of $6,179. In the adherent group, the mean OHA medication expense was $132 and 200 (33.4%) patients had at least one hospitalization with an average cost of $5,459. The leading comorbidities were hypertension and ischemic heart disease in both groups. After adjusting for confounders, adherence to OHA was associated with lower hospital cost (β = -416, p<0.0001) and higher OHA medication expenses (β =256, p<0.0001). Other factors significantly affecting hospital cost were age of DM2 onset (β =11.1, p<0.0001), female gender (β =-135, p=0.003), ischemic heart disease heart disease (β =701, p<0.0001), stroke (β =536, p=0.006) and hypertension (β =-125, p<0.0001).

Conclusion: In our observational analysis of Medicaid claims data, healthcare costs were significantly lower in patients with DM2 who were adherent to their OHA when compared with those who were non-adherent even after accounting for the higher medication costs.
Facebook and depression: How people with depression use Facebook to manage their depression.
Maryam Zolnoori, Priya Nambisan, Timothy B. Patrick
zolnoori@uwm.edu

Introduction
Internet has provided efficient and effective platform for accessing/sharing health information among patients and caregivers. The recent study conducted by Moorhead, Hazlett, Harrison, Carroll, Irwin, Hoving 1 showed that 61% of adults go online to search for health information and 39% use social media to communicate with patients with the same experiences. To respond to the needs for health information, several applications were created on web 2.0 to allow generating and sharing contents by healthcare consumers. Applications such as virtual content communities (eg, YouTube) and social networking sites (eg, Facebook and twitter) deal with two dimensions of user experiences including cognitive and emotional dimensions 2.
